Tutorials 38

Installing and maintaining IBM API Connect 39
Kubernetes, OpenShift, and Cloud Pak for Integration 40
Planning your deployment 40
Prerequisite skills for administering API Connect 40
Key concepts: Custom Resources, Operators, and Operands 40
Deployment overview for endpoints and certificates 41
Deployment profiles, topologies, and strategies 41
Deployment and component profiles 42
API Connect deployment profiles for OpenShift and Cloud Pak for Integration 42
Component profiles, CPU limits, memory limits, and licensing 44
Management subsystem deployment profile limits 44
Portal component deployment profile limits 51
Analytics component deployment profile limits 53
DataPower gateway deployment profile limits 55
Multiple data center deployment strategies 55
Two data center warm-standby deployment on Kubernetes and OpenShift 56
Two data center deployment examples and diagrams 57
OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration 60
Network requirements for inter-subsystem communication 61
Enable JWT security instead of mTLS 62
In-cluster service communication between subsystems 63
Kubernetes ingress controller prerequisites 63
Persistent Volume (PV) requirements 64
Load balancer configuration 65
Firewall requirements 67
Planning your analytics deployment 70
Key Concepts: Cert-manager, Issuers, and Secrets 71
Webhooks deployed and managed by the API Connect Operator 73
Administering API Connect in your container environment 74
Namespaces in your container environment 74
Custom Resources and Custom Resource Definitions 74
Managing your API Connect CRs 76
Installing API Connect 76
Deployment requirements 76
IBM API Connect Version 10 software product compatibility requirements 79
API Connect licenses 80
Deployment procedures 80
Obtaining product files 81
Verifying the integrity of IBM product files 83
Deploying on Kubernetes 84
Deploying operators and cert-manager 84
Deploying operators in a single-namespace API Connect cluster 84
Deploying operators in a multi-namespace API Connect cluster 86
Installing cert-manager and certificates in a two data center deployment 89
Customizing certificates during installation on Kubernetes 90
Generating custom certificates using cert-manager 93

Generating custom certificates using cert-manager in a two data center deployment 94
Generating custom certificates manually 95
Deploying API Connect subsystems with custom certificates 96
Installing the API Connect subsystems 97
Installing the management subsystem 98
Installing the gateway subsystem 100
Installing the developer portal subsystem 103
Defining multiple portal endpoints for a Kubernetes environment 106
Installing the analytics subsystem 107
Creating the analytics CR 107
Installing analytics 109
Installing a two data center deployment on Kubernetes 109
Converting a single data center to a two data center deployment on Kubernetes 113
Troubleshooting installation on Kubernetes 117
Deploying on OpenShift and Cloud Pak for Integration 118
Configuring FIPS support on OpenShift 118
Preparing for installation 121
Operator, CASE, and platform requirements 122
API Connect configuration settings 122
Basic configuration settings 123
Management subsystem settings 124
Gateway subsystem settings 126
Developer Portal subsystem settings 128
Analytics subsystem settings 128
Additional Kubernetes settings 129
Configuring timeouts for management endpoints 130
Installation procedures with IBM Cloud Pak for Integration 131
Installing API Connect in a single namespace on OpenShift 131
Installing operators 131
Setting up a certificate issuer 135
Installing the management subsystem in a shared namespace 137
Installing the gateway subsystem in a shared namespace 140
Installing the portal subsystem in a shared namespace 143
Installing the analytics subsystem in a shared namespace 146
Installing API Connect subsystems in different namespaces or environments on OpenShift 149
Installing operators 149
Installing the management subsystem 152
Extracting the management ingress-ca certificates 156
Installing the gateway subsystem 156
Installing the portal subsystem 161
Installing the analytics subsystem 164
Installing with the top-level CR on OpenShift 167
Installing operators 167
Installing API Connect 171
Air-gapped installation 173
Installing with a bastion host 174
Installing with a portable computer or storage device 178
Installing a two data center deployment with Cloud Pak for Integration 182
Planning and initial preparation 183
Preparing your active data center 183
Preparing your warm-standby data center 186
Installing API Connect on the active data center 187
Installing API Connect on the warm-standby data center 189
Installing a two data center deployment on OpenShift 191
Planning and initial preparation 192
Preparing your active data center 192
Preparing your warm-standby data center 194
Installing API Connect on the active data center 198
Installing API Connect on the warm-standby data center 200
Enable additional features post-install 202
Enable management CA verification on REST API calls 202
Enable JWT security and disable mTLS between subsystems 203
Troubleshooting installation on OpenShift 203
Upgrading API Connect 205
Upgrading on Kubernetes 205
Planning your API Connect upgrade on Kubernetes 206
Pre-upgrade preparation and checks on Kubernetes 208
Upgrading DataPower Operator and Operand independently of the APIC 210
Upgrading API Connect on Kubernetes 211
Upgrading the management subsystem on Kubernetes 214
Upgrading the portal subsystem on Kubernetes 214
Upgrading the analytics subsystem on Kubernetes 215

Upgrading the gateway subsystem on Kubernetes 216
Troubleshooting upgrades on Kubernetes 217
Enabling gateway peering and verifying cluster status 218
Upgrading on OpenShift and Cloud Pak for Integration 219
Planning your API Connect upgrade on OpenShift 219
Operator, CASE, and platform requirements for upgrading 221
Pre-upgrade preparation and checks on OpenShift 222
Resolving duplicate users before upgrade on Cloud Pak for Integration 224
Pre-upgrade preparation for air-gapped environment using a bastion host 226
Pre-upgrade preparation for air-gapped environment using a portable storage device 229
Upgrading API Connect on OpenShift 234
Troubleshooting upgrade on OpenShift 238
Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.7 or later 242
Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.5 243
Upgrading a 2DCDR deployment on Cloud Pak for Integration from V10.0.7 or later 245
Upgrading a 2DCDR deployment on Cloud Pak for Integration from V10.0.5 246
Maintaining API Connect 248
Advanced configuration 249
Installing License Service 249
Installing the Automated API behavior testing application 249
Installing the toolkit 251
Customizing user-facing certificates 253
Changing deployment profiles on Kubernetes and OpenShift 253
Changing deployment profiles on OpenShift top-level CR 254
Changing the deployment profile on Cloud Pak for Integration 255
Replica override for microservices 255
Enabling Developer Portal feature flags on Kubernetes 256
Enabling Developer Portal feature flags on OpenShift and Cloud Pak for Integration 257
Enabling UI feature flags on Kubernetes 259
Enabling UI feature flags on OpenShift and Cloud Pak for Integration 259
Adding external annotation to routes and ingresses 260
Advanced configuration for the management subsystem 261
Updating management subsystem password, keys, and secrets 261
Changing the cloud administrator password 262
Changing the database encryption key 262
Changing the registration client_id and client_secret for applications 264
Configuring maximum size of client requests to the Management subsystem 266
Setting rate limits for public APIs on the management service for a Kubernetes environment 266
Enabling API discovery on Kubernetes 267
Enabling governance on Kubernetes 269
Configuring monetization on Kubernetes 270
Enabling billing feature on OpenShift and Cloud Pak for Integration 272
Restarting the Management subsystem pods 272
Disabling the PDB for the management EDB database 273
Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later 274
Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later 274
Advanced configuration for the analytics subsystem 275
Advanced configuration for the gateway subsystem 276
Customizing a DataPower deployment 276
Updating the gateway password, secrets, and certificates 276
Changing the gateway administrator password 277
Changing the gateway client secret 278
Updating the gateway peering certificate 278
Updating the gateway director and invocation endpoint profiles 278
Overriding the default DataPower image, version, and license 278
Overriding pod CPU and memory settings 279
Enabling autoscaling of gateway pods 279
Configuring rate limits on the gateway nodes 280
Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment 281
Overriding DataPowerService spec properties 282
Advanced configuration for the portal subsystem 282
Updating portal keys and secrets 282
Changing the secret for portal data and system tools 282
Changing the portal client_secret 284
Backing up, restoring, and disaster recovery 284
Backing up and restoring the management subsystem 285
Taking a management infrastructure configuration backup 285
Configuring management database backups 286
Running an on-demand backup of the management database 288
Restoring from a management database backup 289
Restoring the management database with a backup CR 289
Restoring the management database with a backup ID 290

Recovering from a disaster 291
Troubleshooting management database backup and restore 292
Backing up and restoring the developer portal 294
Taking a portal infrastructure configuration backup 294
Configuring portal database backups 295
Running an on-demand backup of the portal database 297
Managing your remote portal database backups 299
Restoring from a portal database backup 299
Recovering from a disaster 302
Troubleshooting portal database backup and restore 303
Backing up and restoring the analytics subsystem 304
Backing up and restoring on OpenShift top-level CR 304
Backing up your OpenShift top-level CR API Connect deployment 304
Disaster recovery on OpenShift top-level CR 304
Backing up and restoring on Cloud Pak for Integration and OpenShift top-level CR 305
Backing up your Cloud Pak for Integration API Connect deployment 305
Recovering from a disaster on Cloud Pak for Integration 306
Maintaining a two data center deployment 308
Key concepts of 2DCDR and failure scenarios 308
Failing over to the warm-standby 310
Backup and restore requirements for a 2DCDR deployment 313
Removing a two data center deployment 313
Verifying replication between data centers 316
Synchronizing the ingress-ca certificates between sites 317
Troubleshooting a two data center deployment 318
Renewing TLS certificates 320
Renewing cert-manager controlled certificates 321
Renewing the management-ca with the ManagementSecretRotation CR 321
Renewing the portal-ca with the PortalSecretRotation CR 322
Renewing the analytics CA 323
Renewing the ingress-ca 324
Copying renewed ingress-ca to subsystems in different namespaces 325
Renewing end-entity certificates 325
Monitoring cert-manager certificate renewal 326
Renewing custom certificates 326
List of Issuers, CA certificates, and secrets 327
List of ingress certificates 327
List of intra-subsystem certificates 329
V2018 upgrade: List of certificates to update manually 331
Renewing certificates in a two data center deployment on Kubernetes and OpenShift 331
Monitoring and health checks 333
Monitoring on Kubernetes 333
Monitoring subsystems on Kubernetes 333
Monitoring Postgres disk usage 333
Monitoring platform health using Kubernetes events 335
Monitoring on OpenShift 335
Monitoring the API Connect cluster on OpenShift 335
Monitoring Postgres disk usage on OpenShift 337
Monitoring platform health on Red Hat OpenShift using Kubernetes events 338
Monitoring on Cloud Pak for Integration 339
Monitoring the API Connect cluster on Cloud Pak for Integration 339
Monitoring Postgres disk usage on Cloud Pak for Integration 340
Obtaining simple health check data of Developer Portal sites by using a REST API call 342
Logging 343
Gathering logs 343
Changing logging levels 344
Troubleshooting 344
Power-cycling check on OpenShift and Cloud Pak for Integration 345
Uninstalling API Connect 345
Uninstalling API Connect subsystems 345
Removing API Connect 347
Removing API Connect on OpenShift or Cloud Pak for Integration 349
VMware 350
Planning your deployment 351
Prerequisite skills for administering API Connect on VMware 351
Deployment overview for endpoints 351
Planning your deployment topology and profiles 352
Enable JWT instead of mTLS 353
Firewall requirements on VMware 353
Firewall enabled ports for clustered OVA deployments 356
Load balancer ports for clustered OVA deployments 357
Load balancer configuration in a VMware deployment 357

Multiple data center deployment strategies 360
Two data center warm-standby deployment strategy on VMware 361
Planning your analytics deployment 362
API Connect TLS certificate best practices 362
Customizing your user-facing certificates 363
Installing API Connect 364
IBM API Connect Version 10 software product compatibility requirements 365
VMware deployment overview and requirements 365
API Connect licenses 367
Preparing to install API Connect in VMware 368
Verifying the integrity of IBM product files 369
Installing the management subsystem on VMware 370
Preparing the management subsystem for deployment 370
Deploying the management subsystem OVA 373
Verifying the management subsystem installation 374
Installing the analytics subsystem on VMware 376
Preparing the analytics subsystem for deployment 376
Deploying the analytics subsystem OVA 379
Verifying installation of the analytics subsystem 380
Installing the developer portal subsystem on VMware 381
Preparing the portal subsystem for deployment 382
Configuring two NICs on the portal 386
Deploying the portal subsystem OVA 386
Verifying installation of the portal subsystem 387
Defining multiple portal endpoints for a VMware environment 388
Deploying DataPower Gateway virtual appliance 391
Installing DataPower Gateway 391
Configuring DataPower Gateway for API Connect 392
Configuring DataPower API Gateway 392
Configuring DataPower Gateway (v5 compatible) 395
Best practices for enabling TLS in API Connect peer groups and managing certificate expiry 398
Sample configuration for multiple peering objects on gateway services external to Kubernetes 399
Post-deployment steps 403
Installing a two data center deployment 403
Upgrading API Connect 410
Planning your API Connect upgrade on VMware 410
Pre-upgrade preparation and checks VMware 412
Control Plane files for earlier releases 414
Upgrading management, portal, and analytics on VMware 417
Upgrading DataPower Gateway 421
Upgrading a two data center deployment 422
Troubleshooting upgrades on VMware 422
Maintaining API Connect 424
Advanced installation on VMware 425
Installing the IBM License Metric Tool on VMware 425
Installing the toolkit 251
Installing the Automated API behavior testing application 427
Advanced configuration on VMware 428
Adding a static route on a virtual machine 428
Adding disk space to a VMware appliance 429
Appliance boot mode configuration 430
Running commands at boot with iso-ignored boot mode 431
Changing deployment profiles on VMware 432
Changing the DNS server configuration 433
Configuring API Connect subsystems in a cluster 434
Overriding NTP server configuration 437
Configuring SSHD to limit access to your deployment 438
Enabling Developer Portal feature flags on VMware 439
Specifying a range of allowable client IP addresses for the portal 440
Managing an appliance data disk 440
Replica override for microservices on VMware 440
Testing a new configuration against a current cluster 441
TLS certificate concepts and operations 441
Certificate reference VMware 442
Customizing user-facing certificates 447
Certificate expiry and renewal 448
Extracting and copying certificates 449
Rotating the portal intra-subsystem certificates on VMware 449
Updating the gateway peering certificate 450
Apicup certs command reference 451
Certificate validation reference 452
Use JWT security instead of mTLS between subsystems 452

Credentials and encryption secrets reference 453
Advanced configuration for management subsystem 453
Setting rate limits for public APIs on the management service 454
Configuring maximum size of client requests to the Management subsystem on VMware 455
Enabling API discovery on VMware 456
Enabling governance on VMware 457
Configuring monetization on VMware 458
Enabling UI feature flags on VMware 459
Configuring rate limits on the gateway nodes on VMware 460
Backing up and restoring on VMware 461
Project directory backup 461
Backing up and restoring the management subsystem 462
Backing up your management certificates 462
Configuring management database backups 463
Running an on-demand backup of the management database 465
Restoring from a management database backup 466
Management subsystem disaster recovery 467
Backing up and restoring the portal subsystem 468
Configuring portal database backups 469
Running an on-demand backup of the portal database 471
Restoring the portal database backup 472
Portal subsystem disaster recovery 473
Backing up and restoring the analytics subsystem 473
Using VM snapshots for infrastructure backup and disaster recovery 474
Disaster recovery 475
Disabling and re-enabling the analytics subsystem on VMware 475
Maintaining a two data center deployment 476
Backup and restore considerations for a two data center deployment 476
How to failover a two data center deployment 477
Failover steps when active site is responsive 477
Failover steps when active site is inaccessible 478
Removing a two data center deployment 480
Monitoring and health checks 480
Checking cluster health on VMware 481
Monitoring Postgres disk usage on VMware 481
Obtaining simple health check data of Developer Portal sites by using a REST API call 482
Monitoring with SNMP 483
Logging 484
Configuring remote logging for a VMware deployment 484
Gathering logs in a VMware environment 486
Changing logging levels 488
Troubleshooting 489
Recreating a calico pod that is in the CrashLoopBackOff state 489
Running a filesystem check on a VMware root partition 489
Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment 490
Troubleshooting analytics on VMware 491
Migrating v5-compatible APIs to API Gateway 491
Preparing the environment 491
Planning your API migration 492
Downloading and extracting the data to migrate 492
Converting v5-compatible API definitions 493
Reviewing APIs converted to DataPower API Gateway 498
Messages generated during conversion of APIs to DataPower API Gateway 498
Parse actions added to the API assembly after migration 534
Fine-tuning APIs after migration 535
Frequently asked questions about migrating APIs to API Gateway 535
Configuring migration options for DataPower API Gateway 537
Pushing custom policies and gateway extensions to the DataPower API Gateway 541
Pushing provider organization data 543
Migrating from v10 to v10 on a different form factor 546
v10 migration overview 547
v10 migration requirements 549
v10 migration steps 551
Preparing the source system 551
Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration 552
Installing the target system on VMware 555
Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration 556
Restoring the target system on VMware 561
Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration 562
Verifying the target system on VMware 563
Migrating from OpenShift to Cloud Pak for Integration on the same cluster 563
v10 migration troubleshooting 564
The API Connect operations tool: apicops 565

Using Config Sync to replicate consumer-side catalog data 565
Downloading the Config Sync utility 566
Running Config Sync as a standalone binary 566

Configuring and managing your server environment 566
Cloud Manager configuration checklist 567
Activating your Cloud Manager user account 567
Accessing the Cloud Manager user interface 568
Defining your Cloud Manager topology 569
Creating an availability zone 570
Registering a gateway service 571
Policies deployed on registration 574
Registering an event gateway service 574
Registering an analytics service 576
Registering a portal service 578
Associating an analytics service with a gateway service 579
Enabling OpenTelemetry configuration 580
Setting visibility for a service 581
Managing authentication and security 582
User registries overview 582
Configuring an Authentication URL user registry 583
Configuring a shared custom user registry 585
Configuring an LDAP user registry in the Cloud Manager 590
Using the CLI to configure a shared LDAP user registry 593
Configuring a Local User Registry 599
Configuring an OIDC user registry in Cloud Manager 600
Setting visibility for a user registry 606
Deleting a user registry 607
Removing a user from a user registry 607
Removing yourself from a user registry 607
Removing another user from a user registry 608
TLS profiles overview 609
Creating a TLS server profile 611
Creating a TLS client profile 612
Defining elliptic curve cryptographic schemes for a TLS client profile 613
Creating a keystore 614
Creating a truststore 615
Managing TLS profiles, keystores, and truststores 615
Using OpenSSL to generate and format certificates 616
OAuth Provider overview 617
Configuring a native OAuth provider 618
Configuring basic settings for a native OAuth provider 620
Configuring scopes for a native OAuth provider 620
Configuring user security for a native OAuth provider 621
Configuring tokens for a native OAuth provider 622
Configuring token management and revocation for a native OAuth provider 623
Configuring introspection for a native OAuth provider 624
Configuring metadata for a native OAuth provider 625
Configuring the OIDC parameters for a native OAuth provider 626
Editing a native OAuth provider by using the API Editor 626
Configuring a third-party OAuth provider 627
Configuring scopes for a third-party OAuth provider 628
Setting the visibility for OAuth providers 629
OAuth concepts for API Connect 630
OAuth user scenario 630
OAuth introspection for third-party OAuth providers 631
Oauth metadata URL and authentication URL 633
Scope 635
Tokens 639
Refresh tokens 639
OAuth revocation URL 640
Authenticating and authorizing through a redirect URL 642
Token management with the DataPower Gateway (v5 compatible) 643
Token management with the DataPower API Gateway 645
Authentication URL 648
Custom forms for user security 649
Creating a custom HTML login form for user security 649
Creating a custom HTML authorization form for user security 650
Securing an API with a JSON Web Token 651
Troubleshooting OAuth 651
Configuring the cloud settings 652
Change the name of your cloud 653
Configuring an email server for notifications 653
Setting up notifications 654

Customizing email notification templates 655
Configuring invitation timeouts 657
Configuring API key settings 657
Using the CLI to modify cloud settings 657
Configuring Base64 encoding for temporary tokens 658
Configuring the password-reset notification and timeout 659
Selecting user registries for Cloud Manager and API Manager 659
Setting a default user registry for Cloud Manager and API Manager 660
Configuring timeouts for access tokens and refresh tokens 661
Viewing platform and UI endpoints 661
Configuring the default gateway services for Catalogs 662
Managing the public/private key pairs for signing tokens 662
Configuring public/private key pairs for tokens 663
Configuring governance in the Cloud Manager 665
The governance ruleset lifecycle in the Cloud Manager 668
Updating rulesets and rules with the toolkit CLI 669
Administering provider organizations 670
Creating a provider organization 670

API Connect overview

IBM® API Connect is an integrated API management offering, with capabilities and tooling for all phases of the API lifecycle. IBM API Connect 10.0.8.2 is a Support Cycle-2 release, and is the follow-on release to 10.0.8.1. Support Cycle-2 (SC-2) is the new name for Long Term Support (LTS), such as the 10.0.5.x and 10.0.1.x. releases. If you're looking for a different version of API Connect, use the Change version list in the navigation pane to select the version that you require.

Key steps of the API lifecycle include create, secure, manage, socialize, monetize, and analyze. IBM API Connect Version 10 delivers enhanced capabilities for the market-leading IBM API management solution. In addition to the ability to deploy in complex, multi-cloud topologies, this version provides enhanced experiences for developers and cloud administrators in your organization.

IBM API Connect has two main focuses: the first is providing best in class API Management tooling, and the second is having a cloud native solution. This allows users to create, manage, and secure applications that are deployed across a variety of on-premises and cloud environments.

The following table explains the key phases in the API lifecycle in more detail.

Table 1. Key phases of the API lifecycle

Lifecycle Phase	Description
Create	Develop and write API definitions from an API development environment, eventually bundling these APIs into consumable products, and deploying them to production environments. For tutorials, walk-throughs, and in-depth guides for building, testing, and deploying APIs and Products in API Connect, see Tutorials, and Developing your APIs and applications.
Secure	Leverage the best-in-class API Gateway, gateway policies, and more, to manage access to your APIs and back-end systems. To learn more about adding security to your API, see *Enforcing security requirements on an API* for the OpenAPI version that you are working with: • OpenAPI 2.0: Enforcing security requirements on an API • OpenAPI 3.0: Enforcing security requirements on an API To learn more about how to add API Gateway policies to your API, see API policies and logic constructs.
Manage	Governance structures are built in to the entire API lifecycle, from managing the view/edit permissions of APIs and Products being deployed, to managing what application developers can view and subscribe to when APIs are deployed. To understand and leverage API Connect management and governance controls along the API lifecycle, see Managing your APIs.
Socialize	API Connect comes with an advanced Developer Portal that streamlines the onboarding process of application developers, and can be completely customized to an organization's marketing standards. To understand more about using the Developer Portal, see Developer Portal: Socialize your APIs.
Monetize	Bundle APIs into Products and Plans with monetization schemes that are built into those Plans, thereby opening up digital revenue streams. To understand more about how to leverage monetization strategies in API Connect, see Monetizing your Products.
Analyze	Developers and Product Managers alike are given the tooling in API Connect to understand their API traffic patterns, latency, consumption, and more to make data driven insights into their API initiatives. To learn more about how to leverage API Connect analytics tooling, see API Analytics.

API Connect has four major components: API Manager, Analytics, Developer Portal, and Gateway. These four components can be deployed in a variety of hybrid and multi-cloud topologies. The API Connect infrastructure can either be deployed and managed by an IBM team in an IBM Cloud environment, or it can be deployed and managed by the customers in their own dedicated environment or third-party cloud. There is also the option for having hybrid scenarios, for example, with the API Connect Reserved Instance Offering, users are able to have their API Manager and Developer Portal running in the IBM Cloud, but then place remote gateways next to their back-end services.

Configuration of customer deployed API Connect clouds is done through the Cloud Manager. For in-depth guides and instructions see Configuring and managing your server environment.

For information about the API Connect components that provide these capabilities, and details about the strategy for packaging and publishing APIs for use by API consumers, see:

- Packaging strategy and terminology in API Connect
- API Connect components

Note: For a comprehensive technical guide to best practices, considerations, and deployment options for API Connect, see the API Connect v10.x Whitepaper.

What's new in the latest release (version 10.0.8.2)

Find out about the newest features and the latest updates in API Connect.

IBM® API Connect 10.0.8.2 is a Support Cycle-2 release, and is the follow-on release to 10.0.8.1. Support Cycle-2 (SC-2) is the new name for Long Term Support (LTS), such as the 10.0.5.x and 10.0.1.x. releases.

Attention: IBM has identified and addressed an issue that may occur during upgrades to API Connect version 10.0.8.2, affecting database encryption transformation. To resolve this issue, we have released **v10.0.8.2-ifix1** as a full installation image.

- **New deployments:** Perform a fresh installation using **v10.0.8.2-ifix1** to avoid encountering this issue.
- **Existing deployments:** If you have already upgraded to v10.0.8.2 and are experiencing this problem, upgrade directly to **v10.0.8.2-ifix1** (a complete replacement, not an incremental patch). If you have not yet upgraded to 10.0.8.2 then upgrade directly to **v10.0.8.2-ifix1**.

Before upgrading to APIC **v10.0.8.2-ifix1**, you must run the **`apicops preupgrade`** command to check for:

- Recent encryption-related issues
- Invalid gateway-extensions

For detailed upgrade or installation steps, refer to the IBM documentation.

Product files and release notes

- Access the latest files from IBM Fix Central by searching for the API Connect product and your installed version. Full installation files for IBM API Connect can be downloaded from Passport Advantage.
- For details on the specific APARs that are included in this release, links to downloads, and additional blogs and conference notices, see the IBM API Connect 10.0.8.2 Support Announcement page.
- For more details about support lifecycle policies at IBM, such as Support Cycle-2, see IBM Software Support Lifecycle Policies.

Upgrading from API Connect 10.0.5.x

If you're upgrading to 10.0.8.x from 10.0.5.x, you should also note the major updates that were delivered to API Connect in versions 10.0.6.0 and 10.0.7.0. For a list of the key changes, see Upgrading to 10.0.8.x from 10.0.5.x.

IBM API Connect 10.0.8.2 includes the following enhancements.

What's new for Developers

AI Gateway functionality on DataPower® API Gateway

Previously, there was a restriction that prevented you from enabling AI Gateway if your own gateway-extension was deployed on the gateway, and vice-versa. This limitation has now been removed starting with version **10.0.8.2**.

With this change, you can now deploy your own gateway-extension and enable AI Gateway on the same gateway instance without any restrictions

For more information, see Using the AI Gateway to support APIs for AI applications.

Out-of-the-Box (OOTB) gateway policy deployment

Starting in IBM API Connect 10.0.8.2, when a DataPower API Gateway is created (registered) in IBM API Connect, the system will automatically deploy out-of-the-box (OOTB) gateway policies.

For this release, the following OOTB policy is deployed upon gateway registration: Token Mediation policy.

When upgrading to IBM API Connect 10.0.8.2, all existing DataPower API Gateways will automatically receive the new OOTB policy(ies) after the API Management subsystem upgrade.

AI Gateway feature adds support for Gemini

API Connect now provides a policy that enables your API to send requests to Gemini, and supports the following operations:

- **`POST models/[model]:generateContent`**
- **`POST models/[model]:countTokens`**
- **`POST models/[model]:embedContent`**
- **`POST models/[model]:batchEmbedContents`**
- **`GET models/[model]`**
- **`GET models`**

For more information, see Using the AI Gateway to support Gemini APIs.

What's new for API product managers

API Product recommendation for consumers

The new API Product Recommendations block on the Developer Portal displays product recommendations for the API consumers. The API products are suggested to the users based on the current subscription plan and browsing history. For more information, see Configuring API product recommendations.

New analytics filter operators

Analytics filters now include two new operators: **`isset`** and **`isnotset`**.

- **`isset`**: This filter displays only fields that have any value, including non-empty strings, numbers, or any other non-null value.
- **`isnotset`**: This filter displays fields that contain **`empty`** strings or **`null`** values.

For more information, see Filtering displayed data.

Enhanced table sorting in analytics discover view
You can now sort the discover table in ascending or descending order by clicking on the column headers. For more information, see Discover view.

Enhancements to Analytics detail reports
Analytics detail reports have been enhanced to include charts for data sent and received. This improvement applies to reports for the following:

- APIs
- Products
- Applications
- Consumer organizations

For more information, see Reports view.

What's new for Developer Portal site administrators

New Case Studies Module in the Developer Portal
The Developer Portal now has a new module which introduces a new content type called **Case Modules**. This will help community managers and API Product business owners to promote and highlight API Products socialized in the Developer Portal. For more information, see Adding a case study.

What's new for DevOps

Configuring analytics offload plugins with a password-protected keystore
You can now use a secret to provide the password to be used with a password-protected keystore for storing the CA certificate for the target offload server instead of providing the password in plain text. For more information, see Configuring offload server certificates on Kubernetes and OpenShift.

Cert-manager is upgraded to version 1.16.3
API Connect 10.0.8.2 uses cert-manager 1.16.3. If your environment requires a manual installation or upgrade of cert-manager, the instructions are included as part of the API Connect installation and upgrade procedures.

Support for external annotation and label configuration
You can now configure external annotations and labels to route and ingresses. For more information, see Adding external annotation to routes and ingresses.

- **What's new in version 10.0.8.1**
  IBM API Connect 10.0.8.1 is the follow-on fix pack to 10.0.8.0. This page details the enhancements in IBM API Connect Version 10.0.8.1 since 10.0.8.0.
- **What's new in version 10.0.8.0**
  IBM API Connect 10.0.8.0 is a Support Cycle-2 release, and is the follow-on release to the prior Continuous Delivery (CD) releases 10.0.7.0 and 10.0.6.0. Support Cycle-2 (SC-2) is the new name for Long Term Support (LTS), such as the 10.0.5.x and 10.0.1.x. releases. This page details the enhancements in API Connect 10.0.8.0 since 10.0.7.0.
- **Upgrading to 10.0.8.x from 10.0.5.x**
  If you're upgrading to IBM API Connect 10.0.8.x from 10.0.5.x, you should note the following major updates that were delivered in the earlier 10.0.x releases of 10.0.6.0 and 10.0.7.0.

What's new in version 10.0.8.1

IBM® API Connect 10.0.8.1 is the follow-on fix pack to 10.0.8.0. This page details the enhancements in IBM API Connect Version 10.0.8.1 since 10.0.8.0.

For details on the specific APARs that are included in this release, links to downloads, and additional blogs and conference notices, see the IBM API Connect 10.0.8.1 Support Announcement page.

What's new for Developers

AI Gateway functionality on DataPower® API Gateway
Enabling this feature activates AI Gateway policies on the DataPower API Gateway, allowing you to create REST proxies that utilize the AI Gateway to control access to AI models. For more information, see Using the AI Gateway to support APIs for AI applications.

Local Test Environment updates

- You can now configure the toolkit credentials for the Local Test Environment by using the following command:

  ```
  apic client-creds:set ~/.apic-lte/credentials.json
  ```

- You can now launch the API Designer user interface by using the following command:

  ```
  APIC_DESIGNER_CREDENTIALS=~/.apic-lte/credentials.json <path-to-designer>
  ```

For more information, see Starting the Local Test Environment and Preparing an API for testing in the Local Test Environment

Language configuration for CLI command outputs
You can now set the language for CLI command outputs by using the **--lang** flag. This flag allows you to receive command outputs in your preferred language from a list of supported languages. For more information, see Setting the language.

Bulk import feature for AsyncAPIs from EEM
A bulk import feature is now available, enabling users to select and import multiple AsyncAPI definitions from Event Endpoint Manager (EEM) into API Connect. For more information, see Importing an AsyncAPI from Event Endpoint Management.

New statuses for tracking product lifecycle operations.
You can now track product lifecycle operations for DataPower® API Gateway-compatible products using new statuses. For more information, see Publishing a draft product.

What's new for API product managers

Analytics client dashboard includes longitude and latitude
: The map of IP addresses in the client dashboard now shows the longitude and latitude, in addition to the geohash.

Analytics consumption report
: A new API consumption report is available from the Cloud Manager and API Manager UIs. The consumption report contains the same data as the consumption dashboard, and can be used to report usage for consumption-based licensing. For more information, see Counting total API calls.

Governance service updates
: The following governance service updates are now available.

- Product scanning. You can now run governance scans on the products in your catalogs and spaces, to validate the products that they contain, as well as running scans on the APIs. For more information, see Scanning your catalogs and spaces.
- Tags in API rulesets. You can now add one or more tags to your governance service API rulesets. If you have matching tags in both your APIs and rulesets, then the appropriate rulesets are pre-selected for your validation scans, and the governance process can be run more quickly and effectively. For more information, see Configuring governance in the Cloud Manager and Configuring governance in the API Manager.

The Config Sync feature is no longer a Technology Preview
: The Config Sync feature is fully released and supported. See Using Config Sync to replicate consumer-side catalog data.
Config Sync records the number of resources that are processed during a synchronization in the analytics subsystem. The results can be viewed in the consumption dashboard. For users on call volume licensing, the amount of data that is synchronized is converted to API calls and is included in your call volume license.

What's new for API consumers

New analytics charts in the Developer Portal
: The Developer Portal analytics view has two new charts at both application and consumer organization scope:

- Top APIs over time.
- Top products over time.

New features in Consumer Catalog
: The Consumer Catalog now supports the following:

- Local user registry, OIDC user registry, or LDAP registry.
- Ability to view analytics for an application.
- Ability to delete consumer accounts.

For more information, see Consumer Catalog and Developer Portal considerations

What's new for Developer Portal site administrators

Limiting API details visibility for non-authenticated users
: In the previous releases, both the authenticated and non-authenticated users can view all the API details if the respective API product is viewable. Now, you can limit the API details visibility for non-authenticated users by selecting the **`Show API details to anonymous users`** setting in the Developer Portal. For more information, see Configuring the API details visibility for non-authenticated users.

Additional options for selecting email recipients in the Portal mailing wizard
: The Portal users can now select a consumer organization or groups of consumer organizations in mailing wizard. For more information, see Emailing consumer organizations.

Admin Portal updated to Drupal 10.3
: The Admin Portal has been updated to Drupal 10.3 which uses a new Admin navigation. The portal tutorials and other Drupal admin related docs are updated to reflect the new Admin navigation.

What's new for DevOps

Support for restricted pod security enforcement using namespace labels
: API Connect 10.0.8.1 on Kubernetes now supports deploying subsystems in namespaces configured with the **`"enforce=restricted"`** policy.

Replicating analytics data to a 2DCDR warm-standby data center
: If you have a two data center warm-standby deployment, you can configure the analytics subsystem in your active data center to offload incoming API event records to the analytics subsystem in your warm-standby data center. For more information, see Replicating analytics data to a 2DCDR warm-standby data center.

Automated API behavior testing: Smart generation and Autotest assist are now available in API Connect on Kubernetes and OpenShift Container Platform
: Beginning with API Connect 10.0.8.1, the Smart generation and Autotest assist features of the Automated API behavior testing application are available in API Connect when deployed on Kubernetes or OpenShift Container Platform. These test features are not available when you deploy API Connect on VMware.
For instructions on enabling these features on Kubernetes or OpenShift Container Platform, see the "Enabling Autotest Assist Smart Generation" section of Installing the Automated API behavior testing application.

Analytics data retention period defined by deployment profile
: The default retention period of analytics data was set to 30 days for one replica profiles and 90 days for three replica profiles. In V10.0.8.1, the default retention period is set according the analytics deployment profile:

Table 1. Default analytics retention periods

Profile	Retention (days)
n1xc2.m16	3
n1xc4.m32	30
n1xc6.m48	45

Profile	Retention (days)
n3xc4.m16 - DEPRECATED	2
n3xc4.m32	30
n3xc6.m48	45
n3xc8.m64	45

Analytics offload support for two parallel pipelines
: In previous releases, all analytics offload targets were configured in `spec.external.offload` and run in series. A second pipeline configuration section (`spec.external.offload2`) is added in V10.0.8.1, which runs in parallel. For more information about analytics offload, see Offload to third-party systems.

Ability to increase analytics Logstash persistent queue size
: A new `ingestion.queue.defaultQueueSize` property is added to the analytics subsystem. Users can increase the queue size following the steps here: Logstash persistent queue.

Filter `apicup certs list` output for user-facing endpoints and credentials
: Two new arguments are added to `apicup certs list`:

  - `apicup certs list --endpoints` outputs only user-facing endpoint certificates.
  - `apicup certs list --creds` outputs only credentials and encryption secrets.

Update to Ubuntu Linux on VMware
: The Ubuntu Linux version is upgraded to from v20.04 to v22.04. Extra upgrade steps are required, see Upgrading management, portal, and analytics on VMware.

Cert-manager is upgraded to version 1.12.13
: API Connect 10.0.8.1 uses cert-manager 1.12.13. If your environment requires a manual installation or upgrade of cert-manager, the instructions are included as part of the API Connect installation and upgrade procedures.

Support for API Connect operator at different version from API Connect subsystems
: You can now run the API Connect operator at a different version from the API Connect subsystems. See the supported combinations in the installation documentation for your platform Kubernetes, OpenShift, and Cloud Pak for Integration.

What's new in version 10.0.8.0

IBM® API Connect 10.0.8.0 is a Support Cycle-2 release, and is the follow-on release to the prior Continuous Delivery (CD) releases 10.0.7.0 and 10.0.6.0. Support Cycle-2 (SC-2) is the new name for Long Term Support (LTS), such as the 10.0.5.x and 10.0.1.x. releases. This page details the enhancements in API Connect 10.0.8.0 since 10.0.7.0.

For details on the specific APARs that are included in this release, and links to downloads, blogs, and conference notices, see the IBM API Connect 10.0.8.0 Support Announcement page.

Upgrading from API Connect 10.0.5.x

If you're upgrading to 10.0.8.x from 10.0.5.x, you should also note the major updates that were delivered to API Connect in versions 10.0.6.0 and 10.0.7.0. For a list of the key changes, see Upgrading to 10.0.8.x from 10.0.5.x.

What's new for Developers

Support for OIDC discovery
: API Connect now provides native support for OIDC discovery, which allows a client to query attributes of the provider itself. You can supply the provider's URL as the OpenIDConnect Discovery path while Configuring the OIDC parameters for a native OAuth provider.

The Automated API behavior testing application is now available from the API Manager home page
: If your cloud administrator installed the Automated API behavior testing application, you can access it by clicking the Test tile on the API Manager home page. For information on using the test application, see Testing an API with Automated API behavior testing.

New API discovery capability
: Now, you can quickly discover the APIs in your organization, and pull them automatically into your API Manager, by using GitHub, DataPower® API Gateway proxy, and OpenTelemetry collectors. For more information, see API discovery.

Governance service updates
: The following updates to the governance service are now available:

  - The governance service is now available from the main navigation bar by clicking the Governance icon  . Previously, the governance service was accessed from the Resources section.
  - You can now run scans on your catalogs and spaces to validate the APIs that they contain by using Spectral rulesets. For more information, see Scanning your catalogs and spaces.
  - The ability to create and manage product rulesets, as well as API rulesets, is now available; see Configuring governance in the Cloud Manager, and Configuring governance in the API Manager.
  - You can now also run validation scans on your product documents, as well as on your API documents. For more information, see Validating an API or product document by using the governance service.
  - Spectral 2.0.1 is now supported.

LoopBack is no longer supported
: Beginning with API Connect 10.0.8.0, LoopBack is no longer supported. LoopBack is not included with the toolkit, and is not discussed in this documentation.

Toolkit CLI documentation relocated
: The toolkit CLI documentation is now published at https://ibm-apiconnect.github.io/clidocs, instead of in the reference section of this collection.

Importing AsyncAPI with Event Endpoint Management

You can now import an AsyncAPI that was exported from Event Endpoint Management. For more information, see Importing an AsyncAPI from Event Endpoint Management.

Creating AsyncAPI with Event Endpoint Management
: You can now create AsyncAPI by using Event Endpoint Management. AsyncAPI managed in Event Endpoint Management is read only in API Connect. For more information, see Creating an AsyncAPI with Event Endpoint Management.

View the subscription task approval history
: You can now view the complete history of subscription task approvals. For more information, see Approving product lifecycle and subscription requests.

Download event logs from the gateway service
: You can now download event logs from the gateway service. For more information, see Reviewing processing status and downloading event logs for gateway.

Added OAuth authorization support for four grant types
: Added OAuth authorization support for the following four grant types:

  - Access Code
  - Application
  - Implicit
  - Password

  For more information, see Sending the API request.

What's new for API product managers

API Connect Backstage plug-in
: The plug-in provides a centralized view of APIs and products across multiple API Connect clouds, organizations, and catalogs. It enables API teams to manage and monitor their API assets efficiently. For more information, see [Technology Preview] Using API Connect Backstage plug-in.

New Consumer Catalog for testing and subscribing to APIs
: You can now use a Consumer Catalog for testing and subscribing to APIs. The Consumer Catalog is a non-customizable, self-service, web-based site for application developers to test and subscribe to the APIs that are published in your catalog. The site uses less resources when compared to the Developer Portal, and offers quick and basic credential access. The Consumer Catalog is ideal for smaller API catalogs and internal users, who are looking for a lightweight consumer experience with basic functionality. A customer can have either a Developer Portal or a Consumer Catalog to test and subscribe to the APIs that are published in your catalog. For more information, see Consumer Catalog and Developer Portal considerations.

New graphical representation of API event latency
: The API latency visualizer has a new horizontal bar that highlights where most of time is spent in the processing of an API call.

Analytics `event_id` generation
: The auto-generated **`event_id`** for analytics API events is now generated based on a hashed version of the **`datetime`**, **`transaction_id`**, and **`client_id`** fields combined by using the SHA1 algorithm.

  This change prevents the analytics subsystem from ingesting duplicated API events, which can be caused by gateway failure.

New **`gateway_type`** field in analytics API events
: The API event records have a new field **`gateway_type`** that indicates the type of gateway and version that processed the API call. For example, **`apigw/10.5.3.0`**. API event record fields are listed in API event fields.
  All gateway types except for the V5 compatible gateway (**`v5c`**), set the new **`gateway_type`** field when they generate API events.

New **`log_policy`** filter option to select API events by logging type
: Filter the view of your API events by log policy. An example use case is when your analytics persistent storage is near its limit and you want to identify all APIs that are set to payload logging. Disabling payload logging on your APIs reduces persistent storage use.

New analytics chart that shows the distribution of API calls across catalogs
: If the same API is published to multiple catalogs, the new chart shows how calls to that API are distributed across your catalogs.

Analytics consumer's user agent string parsed to provide more details about the user
: To provide more information on who is calling your APIs, the consumer's **`http_user_agent`** string is parsed into individual fields in the API event record, such as **`user_agent.os_version`**. The full list of **`user_agent`** fields is documented in API event fields.

Analytics reports can be exported from the UI as PDF
: The detailed reports in Cloud Manager and API Manager UIs can be exported to PDF.

Analytics dashboards updated
: The following analytics dashboards are updated and the charts are redistributed across the updated dashboards to eliminate duplication:

  - New dashboards: Summary, Applications, Client information, Consumers.
  - Removed dashboard: Usage.
  - Renamed dashboards:
    - Monitoring Latency => Latency.
    - Monitoring Data => Data Transfer.
    - Monitoring Status => Status.

Analytics deprecated product report
: The new report identifies which deprecated products are still being called. With this information, you can identify the consumers who are still using the deprecated APIs and encourage them to switch the new APIs.

Analytics reports available at space scope
: All analytics reports are now available at the space scope, in addition to the existing cloud, provider organization, and catalog scopes.

Links to live analytics data from analytics reports
: New Jump to live data button in the detailed analytics reports. Click Jump to live data to switch to the Discover view and see the current live data at the scope of the report.

Bookmark and share links to specific analytics pages, reports, and dashboards

You can bookmark and share analytics pages, reports, and dashboard views that include your filters.

Analytics CLI bucket_interval query parameter
: The analytics CLI dashboards query has a new query parameter: `bucket_interval`. The `bucket_interval` parameter allows you to specify the interval between data points. For example, if you are querying for analytics data for the last week (specified with the `--timeframe` parameter), and you want 4 data points per day, then set `bucket_interval` to 6 hours (`6h`).
The CLI `apic dashboards` operations are documented here: https://ibm-apiconnect.github.io/clidocs/docs/v1008/analytics/apic_dashboards

Analytics GeoIP is enabled by default
: The analytics `ingestion.geoIPEnabled` property is set to true by default.
When `ingestion.geoIPEnabled` is set to true, geographical information that is related to the callers IP address is included in API event records.

New links to analytics data from API Manager UI
: The Manage Catalog and Manage Space views now have links to the analytics data and reports.

Consumer organization reports include a table of applications that are owned by the consumer
: The detailed reports for consumer organizations now include a table that shows the applications that are in the consumer organization, and how many API calls each application made. Clicking the application name in this table takes you to the detailed report for the application. The application reports also include a link to the owning consumer organization report.

Analytics Logstash gelf output plug-in removed.
: The output plug-in https://www.elastic.co/guide/en/logstash/current/plugins-outputs-gelf.html is removed from the analytics subsystem.

What's new for API consumers

New Consumer Catalog for testing and subscribing to APIs
: API consumers can now use a Consumer Catalog for testing and subscribing to APIs. The Consumer Catalog is a non-customizable, self-service, web-based site for application developers to test and subscribe to APIs. The site uses less resources when compared to the Developer Portal, and offers quick and basic credential access. The Consumer Catalog is ideal for smaller API catalogs and internal users, who are looking for a lightweight consumer experience with basic functionality. You can have either a Developer Portal or a Consumer Catalog to test and subscribe to the APIs that are published in a catalog.
For more information, see Consumer Catalog and Developer Portal considerations.

What's new for Developer Portal site administrators

Updates to the `custom-module` and `custom-theme` Developer Portal commands
: The `custom-module:create-import` and `custom-theme:create-import` commands now include a `--wait` flag to give you more control over the command completion time. Previously, the cache rebuild was automatically included as part of the task. Now, if you want to include the cache rebuild as part of the task, you must include the `--wait` flag. If you run the commands without the `--wait` flag, the cache is rebuilt in the background after the task is complete. For more information, see Using the **custom-module** commands and Using the **custom-theme** commands.

New Developer Portal **maintenance** commands
: The following **maintenance** commands can be used to manage the maintenance operations on your Developer Portal:

  - `apic maintenance:disable` - Disable your maintenance operations.
  - `apic maintenance:enable` - Enable your maintenance operations.
  - `apic maintenance:rebuild_node_access` - Rebuild the node access table for your maintenance operations.
  - `apic maintenance:search_api_index_rebuild` - Rebuild and re-index the search API index of your maintenance operations.
  - `apic maintenance:search_api_index_status` - Print the search API index of your maintenance operations.
  - `apic maintenance:status` - Get the current mode of your maintenance operations.

  For more information, see Using the maintenance commands.

New Developer Portal **memcache** commands
: The following **memcache** commands can be used to manage the default caching store operations on your Developer Portal:

  - `apic memcache:disable` - Disable your default caching store operations and set Drupal to use database as its cache.
  - `apic memcache:enable` - Enable your default caching store operations and set Drupal to use RAM as its cache.
  - `apic memcache:get` - Get the status of your `memcache enabled` operations.

  For more information, see Using the memcache commands.

New Developer Portal **role** commands
: The following **role** commands can be used to complete some Drupal role management tasks on your Developer Portal:

  - `apic role:create` - Create a new user role.
  - `apic role:delete` - Delete an unwanted user role.
  - `apic role:add-permission` - Add one or more permissions to a user role.
  - `apic role:remove-permission` - Remove one or more permissions from a user role.
  - `apic role:get` - Get the details of a specific user role as well as the permissions available.
  - `apic role:list` - List the roles based on a specific role or permission.

  For more information, see Using the role commands.

New Developer Portal `sites` command
: You can now use a `sites:reset-upgrade-attempts` command to reset the upgrade attempt counter within the Developer Portal, so that failed upgrades can be retried. For more information, see Using the **sites** commands.

New Developer Portal **queue** commands
: Use the **queue** commands to list the queued and locked platform tasks on your Developer Portal site. For more information, see Using the **queue** commands.

New Developer Portal **user** commands
: The following **user** commands can be used to complete some Drupal user management tasks on your Developer Portal:

- `apic user:add-role` - Add one or more roles to one or more specified user accounts.
- `apic user:block` - Block one or more users.
- `apic user:information` - Retrieve information about your users.
- `apic user:remove-role` - Remove one or more roles from one or more specified user accounts.
- `apic user:unblock` - Unblock one or more users.

For more information, see Using the **user** commands.

Removing keys that begin with `x-ibm` from the OpenAPI document download

By removing the keys that begin with `x-ibm` from the OpenAPI document download, you can download the OpenAPI documents without any key-value pairs that are IBM specific. Enabling this configuration setting removes the information about the API Management provider from the OpenAPI document that is downloaded in the Developer Portal.

For more information, see Removing keys beginning with x-ibm from OpenAPI document download.

What's new for DevOps

Upgrading the Management subsystem from 10.0.7.0 on VMware requires maintenance mode

If you are upgrading from 10.0.7.0 to 10.0.8.0, you must enable maintenance mode for the Management subsystem before you begin the upgrade. For more information, see step Upgrading management, portal, and analytics on VMware.

New cluster management operations in the analytics API for monitoring analytics ingestion

The Logstash APIs can now be run from the analytics REST API and toolkit CLI to provide more information on analytics ingestion.

Logstash API reference: https://www.elastic.co/guide/en/logstash/current/monitoring-logstash.html.

VMware **apicup certs list** command checks for certificate expiry

The **apicup certs list** command that is used on VMware now checks the expiry date of all certificates that are managed by **apicup**. A warning is output for any certificates that are expired or close to expiry.

For more information about checking certificate expiry on VMware, see Certificate expiry and renewal.

Analytics database backup updates

The analytics database backups can now be directed to a remote SFTP server, or stored locally.

The configuration of analytics backups and the restore procedures is simplified to two restore options:

- Repair. Restores indexes that are corrupted or missing.
- Replace. Restores all data from the backup, overwriting any existing data.

Object-store backups now support path-style hosts.

Note: Analytics database backups that were taken on an earlier release cannot be restored on V10.0.8.0.

Analytics `n3xc4.m16` profile is deprecated

If you are using the analytics `n3xc4.m16` component profile, then switch to the `n3xc4.m32` profile. You can switch to the `n3xc4.m32` profile before or after you upgrade to V10.0.8.0. If you continue with the `n3xc4.m16` profile on V10.0.8.0, then your analytics subsystem might encounter memory limits that inhibit how much analytics data you can retain.

Top-level CR deployment profiles n3xc16.m48 and n3xc12.m40 deprecated

The top-level CR deployment profiles `n3xc16.m48` and `n3xc12.m40` are deprecated, and replaced with the profiles `n3xc16.m64` and `n3xc12.m56`. It's recommended that you switch to one of these new profiles after the upgrade to 10.0.8.0 is complete. For information about switching profile, see ../com.ibm.apic.install.doc/config_ocp_switch_profile.html.

Dedicated storage is the default storage type for analytics

For three replica analytics deployments, the dedicated storage type is now the default type. Not applicable to one replica deployments where the only available storage type is shared.

Backup and restore that uses OADP

For Cloud Pak for Integration users, API Connect subsystem backups can be configured with Red Hat OpenShift API for Data Protection (OADP). For more information about OADP, see Administering backup and restore in Cloud Pak for Integration.

Cloud Pak for Integration integration during installation

The default value for `metadata.annotations.apiconnect-operator/cp4i` is now false in all installation scenarios except for installation with the Cloud Pak for Integration Platform UI.

For more information about Cloud Pak for Integration and API Connect integration, see OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration.

New API discovery optional add-on service

API discovery is an optional add-on to API Connect that can be used to quickly discover the APIs in your organization, and pull them automatically into your API Manager. For information about how to enable API discovery, see Enabling API discovery on Kubernetes and Enabling API discovery on VMware.

Cert-manager is upgraded to version 1.12.10

API Connect 10.0.8.0 uses cert-manager 1.12.10. If your environment requires a manual installation or upgrade of cert-manager, the instructions are included as part of the API Connect installation and upgrade procedures.

Backup certificates requirement for VMware

On VMware deployments, to fully backup API Connect you must run a script to extract the management subsystem certificates. For more information, see Backup management certificates.

LDAP connection pooling for DataPower API Gateway

API Connect now supports LDAP connection pooling for the DataPower API Gateway service. Connection pooling reduces overhead and improves performance by maintaining a pool of connections and assigning them as needed. For more information, see the options in step 4 of Registering a gateway service.

SFTP management database backup support

The management subsystem database can be backed up to a remote SFTP server. In V10.0.7.0, only S3-compatible object-store is supported.

The CRD installation and upgrade processes now require additional parameters

In 10.0.8.0, CRD sizes increased. To ensure successful updates to a CRD, include the `--server-side` and `--force-conflicts` parameters in the `kubectl` apply command during installation or upgrade of CRDs.
The following topics now use the updated command to install or upgrade CRDs:

- Upgrading API Connect on Kubernetes
- Deploying operators in a single-namespace API Connect cluster
- Deploying operators in a multi-namespace API Connect cluster

Rollback scenarios for VMware upgrades
: If certain known problems are encountered during the upgrade process on VMware, a rollback is performed automatically.
In all cases, contact IBM Support for help with resolving the underlying problem before you reattempt the upgrade. For more information, see Upgrade fails with an automatic rollback.

New flag for `install` command when upgrading from 10.0.5.x on VMware
: When running the `install` command to upgrade the management subsystem from 10.0.5.x on VMware, use the `--force-operand-update` flag to bypass the Warning state that occurs due to the change from the Crunchy database to EDB. This new flag is included in the upgrade instructions in Upgrading management, portal, and analytics on VMware.

New OIDC registry option to return third-party tokens as separate claims
: By default, OIDC third-party tokens are returned as part of the access_token that is issued by API Connect. Returning the OIDC third-party tokens as separate claims prevents the access_token from growing too large. For more information, see Configuring an OIDC user registry in Cloud Manager.

Event Gateway Service provides access to event endpoints managed by the Event Endpoint Management application
: You can configure your IBM Event Endpoint Management instance to be registered as an Event Gateway Service in API Connect. With the Event Gateway Service, application developers can discover event endpoints and configure applications to access them through the event gateway.

Upgrading to 10.0.8.x from 10.0.5.x

If you're upgrading to IBM® API Connect 10.0.8.x from 10.0.5.x, you should note the following major updates that were delivered in the earlier 10.0.x releases of 10.0.6.0 and 10.0.7.0.

The following list shows the key updates that were delivered to API Connect in versions 10.0.6.0 and 10.0.7.0. For a complete list of all of the features and updates that were delivered in these previous versions, see What's new in version 10.0.6.0 and What's new in version 10.0.7.0 in the 10.0.x IBM Documentation.

Key updates delivered in 10.0.7.0

Replacement of management database operator
: New Postgres operator on the management component: EDB.
EDB replaces the previous Postgres operator Crunchy.

  The change to EDB results in some changes to the procedures for:

  - Install.
  - Upgrade.
  - Backup, restore, and disaster recovery.
  - Form factor migration.
  - Two data center disaster recovery.

Updates to the Developer Portal local backup process
: The Developer Portal now displays local backups, as well as remote backups, when the following command is run:

  ```
  kubectl get portalbackup
  ```

  Previously, local backups were visible only inside the portal pod.
  Note that the Developer Portal retains only three system backups, and three backups per site, for local backups. Running a new local backup will cause the oldest backup to be deleted.

New backup, restore, and disaster recovery documentation
: For Kubernetes, OpenShift, and Cloud Pak for Integration, the disaster recovery section is merged with the backup and restore section, and the requirement to backup the subsystem YAML files and Kubernetes secrets is more prominent. See Backing up, restoring, and disaster recovery.
For VMware, there is a new management subsystem backup section for v10.0.7.0. See Backing up and restoring the management subsystem.

API key now supports multiple uses
: When defining the API key timeout in Cloud Manager, you can additionally choose whether to allow an application to exchange the API key for an access token multiple times. For more information, see Configuring API key timeouts.

OpenShift: Support for FIPS configuration on the API Connect cluster
: For new deployments, you can configure support for the Federal Information Processing Standards (FIPS) protocol on the cluster. You must configure FIPS support before installing the OpenShift cluster. For more information, see Configuring FIPS support.

Cloud Pak for Integration replaces IAM with Keycloak as the OIDC provider, and user accounts might require updates
: Starting with 2023.4 (API Connect 10.0.7.0), Cloud Pak for Integration uses Keycloak as an OIDC provider to authenticate users instead of IAM (Identity and Access Management). Due to differences in how Keycloak and IAM treat user names, you might need to manually merge duplicate user accounts to ensure users can log in after the upgrade. For more information, see Resolving duplicate users before upgrading on Cloud Pak for Integration.

Cloud Pak endpoints are deprecated for API Connect
: Beginning with version 10.0.7.0, API Connect no longer uses the Cloud Pak `cpd` routes for endpoints when deployed as a component of Cloud Pak for Integration. Instead, the component uses the typical default API Connect routes (or the custom endpoints configured in the CR). This change affects both new installations and upgrades from previous versions of the API Connect component in Cloud Pak for Integration.

If you want to deploy the API Connect component with Cloud Pak endpoints, or you need to preserve your existing endpoints (for example, to support existing bookmarks and automation features), you can enable the use of Cloud Pak endpoints when installing or upgrading the API Connect component in Cloud Pak for Integration 2023.4.1 or later. For more information, see Deploying on OpenShift and Cloud Pak for Integration or Upgrading on OpenShift and Cloud Pak for Integration.

VMware: New apicup command to get node status from your local machine

The new `apicup subsys status` command can be run locally to get a node's status without requiring you to first SSH into the node.

Updates to the list of blocked Drupal modules

The following Drupal modules are now unsupported and their installation is blocked in the Developer Portal:

- All of the advanced aggregation modules; `advagg`, `advagg_mod`, `advagg_js_minify`, `advagg_css_minify`, `advagg_ext_minify`, `advagg_validator`, and `advagg_bundler`. These modules are blocked due to incompatibility with the current Drupal version.
- `statistics` module. This module is being deprecated by Drupal.
- `tfa` module. Two-factor authentication isn't available within the Developer Portal. If multi-factor authentication is required, it can be configured within an OpenID Connect (OIDC) user registry; see Creating an OIDC user registry.

For more information about custom modules, see Installing custom modules.

Key analytics updates

The following major analytics updates were delivered:

- Analytics inactive product report. New report in the API Manager UI that highlights products that have no subscriptions, no recent traffic, or no traffic at all.
- Analytics API call volume leaderboard. The reports tab in the analytics view includes a leaderboard of the top APIs, products, plans, applications, and consumer organizations.
- Analytics consumer trend report. The reports tab in the analytics view includes a new consumer trend report that shows changes to the number of applications and subscriptions in consumer organizations over time.
- Detailed API, Product, Plan, Application, and consumer organization analytics reports. Detailed analytics information about specific APIs, products, plans, applications, and consumer organizations. For example, for an API, details of all the consumer organizations that use it. The detailed reports are accessible from the leaderboard in the reports view.
- Analytics persistent queue is enabled by default. The persistent queue feature is enabled by default on new 10.0.7.0 or later installations. If you are upgrading from 10.0.5.x or 10.0.6.0, the feature is automatically enabled during upgrade.
- New analytics API event fields. When using API Gateway 10.5.3 or later, two new fields are included in API event records:
  - `api_resource_id`: String containing the resource ID for the API used by the gateway. Format is `api_name:api_version:method:path`.
  - `gateway_service_name`: The name of the gateway service, as configured in the Cloud Manager UI.
- Monitor analytics ingestion. You can now monitor analytics ingestion by exposing the Logstash API by using the analytics Cluster Management API. For more information, see `Resource: Clustermgmt (ingestion)` in the API for the API Connect analytics subsystem documentation.

Updates to the assembly authoring experience in the API editor

The API editor for viewing and editing the assembly section of APIs in the API Manager and API Designer is updated with a new user experience. The overall capability remains the same, but the visual components for working with the flow canvas, the policy palette, and the policy properties are updated. For more information, see Including elements in your API assembly.

Key updates delivered in 10.0.6.0

Migrate v5-compatible APIs to the DataPower API Gateway

If your deployment includes v5-compatible APIs, they can only be used with the DataPower v5-compatible Gateway (also known as the v5c gateway). To use the v5-compatible APIs with the DataPower API Gateway, you must migrate the APIs to the newer format. For more information, see Migrating v5-compatible APIs to API Gateway.

(Kubernetes, Red Hat OpenShift) Improved platform health status monitoring using Kubernetes events

A new feature is enabled in the IBM `APIConnect` operator on Kubernetes and Red Hat OpenShift to generate CR events whenever there is a change in the top-level CR (APIConnectCluster) or subsystem CRs (`ManagementCluster, GatewayCluster, AnalyticsCluster, PortalCluster`) status conditions. Along with CR status conditions, you can monitor these events by using any third-party alerting system.
For more information, see Monitoring platform health using Kubernetes events or Monitoring platform health on Red Hat OpenShift using Kubernetes events.

Red Hat OpenShift-based deployments now manage foundational services through the API Connect operands

In previous releases of API Connect, a deployment on Red Hat OpenShift (including as a capability in Cloud Pak for Integration) managed the use of IBM Cloud Pak foundational services through dependencies that are enforced by OLM at the operator level. In API Connect 10.0.6.0 and later, the dependency on foundational services is no longer managed at the operator level by OLM, but is instead handled at the operand level by the API Connect operator. This change provides more flexibility going forward by allowing the APIC operator to enforce the dependency only on the operands that actually require it.
This change applies only to new installations and upgrades from 10.0.5.3 or later. For more information, see the appropriate installation instructions for your Red Hat OpenShift environment.

New governance optional add-on service

The governance service is an optional add-on to IBM API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process. For information about how to enable this add-on, see Enabling governance on Kubernetes, and Enabling governance on VMware.

Analytics long-term data

By default analytics event data is retained for up to 30 or 90 days, dependent on the deployment profile. With the new long-term data feature, event data is summarized and added to a new summary data index that has a 1 year default retention period. The summary data allows the product manager to view long-term trends. To view the summary data, the UIs have a new Reports tab, see Analytics dashboards. New REST API and toolkit CLI operations are also provided to access the summary data shown in the UI Reports tab.
Note: If you are upgrading from v10.0.5.x, the summary data is gathered for all new API events after upgrade to 10.0.6.0 or later is complete. Existing API event data from 10.0.5.x is not added to the summary data index.

Updated schema editor design for API definitions

The Definitions section of the API editor in the API Manager and API Designer UIs is updated to improve the user experience when creating and editing schema definitions. For more information, see Defining schemas for an API.

Language versions offered by API Connect

API Connect is offered in several languages, as enabled by the operating platform on which the product is installed.

Note: When API Connect is deployed as a Cloud Pak for Integration capability, it is translated to the same set of languages as the Cloud Pak for Integration product.

- Brazilian Portuguese
- Chinese (Simplified)
- Chinese (Traditional)
- Czech
- Dutch
- English
- French
- German
- Italian
- Japanese
- Korean
- Polish
- Spanish
- Turkish

Known limitations

This page describes the known limitations for API Connect 10.0.7.0 and later.

Note: The limitations that are documented on this page will be removed as they are addressed in the IBM® API Connect product. For the most up-to-date list of product limitations, visit the English version of this page.

Issues transforming database encryption during upgrade operation to v10.0.8.2

IBM has identified and addressed an issue that may occur during upgrades to API Connect version 10.0.8.2, affecting database encryption transformation.
To resolve this issue, we have released **v10.0.8.2-ifix1** as a full installation image.

- **New deployments:** Perform a fresh installation using **v10.0.8.2-ifix1** to avoid encountering this issue.
- **Existing deployments:** If you have already upgraded to v10.0.8.2 and are experiencing this problem, upgrade directly to **v10.0.8.2-ifix1** (a complete replacement, not an incremental patch). If you have not yet upgraded to 10.0.8.2 then upgrade directly to **v10.0.8.2-ifix1**.

Before upgrading to APIC **v10.0.8.2-ifix1**, you must run the **`apicops preupgrade`** command to check for:

- Recent encryption-related issues
- Invalid gateway-extensions

For detailed upgrade or installation steps, refer to the IBM documentation.

Warning message after upgrading from version 10.0.5.x to version 10.0.8.x

After upgrading from API Connect v10.0.5.x to v10.0.8.x, users encounter the following warning message in the analytics component:

```
Warning: The transform of API event data into long term summary data has encountered problems. Contact your system
administrator to investigate further. Long term summary data in reports may not be complete.
```

This warning is displayed because API event data processed by v10.0.5.x cannot be transformed into long-term summary data that uses v10.0.8.x.

The warning does not affect analytics functions or the accuracy of newly processed data in version 10.0.8.x. To resolve the warning automatically, ensure that the data retention policy is properly configured. As older data is purged, the warning clears. To update the retention settings, see Retention and rollover.

Validating from within a ruleset shows all rules

In the governance service, if you click Validate from within a ruleset, the list of rules shown includes rules that are not part of the selected ruleset. To work around this, manually select the rules that you want to use for the validation.

PK12 Key/Cert pairs created with legacy algorithms are not supported for use with the **`apic-gw-service`**

As a result of increased security requirements in IBM API Connect 10.0.8.0, if you configured your non-container gateways to use a PK12 cert/key pair that was generated with legacy algorithms, the Gateway service will fail to start.
Logs will show the following message:

```
[0x88e00011][apic-gw-service][error] apic-gw-service(default): API Connect Gateway Service
caught unhandled rejection: Error: All sentinels are unreachable. Retrying from scratch after 10ms.
Last error: unsupported
```

To resolve this problem, you must create a new key/cert pair and update your **`apic-gw-service`** object with this configuration. This can be done directly through the DataPower crypto tools, or through a third-party tool such as OpenSSLv3. note that OpenSSLv1 cannot be used because defaults to the legacy algorithms.

Gateway pod might show as not ready after upgrade

Gateway pods might fail to display as READY after upgrading to IBM API Connect 10.0.8.0. The pods will show as RUNNING, but 0/1 READY, as in the following example:

```
$ kubectl get pods -n <namespace>
NAME                                                              READY   STATUS      RESTARTS      AGE
...
gwv6-0                                                             1/1     Running     0             1h
gwv6-1                                                             1/1     Running     0             1h
gwv6-2                                                             0/1     Running     0             1h
...
```

To work around this behavior, use the following command delete the pod that is not ready:

```
$ kubectl delete pod gwv6-2 -n <namespace>
```

If there are multiple gateway pods in the cluster, the delete operation will not result in any service disruption.

Gateway services that span data centers

If you want to configure a gateway service that consists of gateways in different data centers, then note the following points:

- This configuration should be used only if TMS is required and an external OAuth provider cannot be used.
- Network latency between sites must be less than 30 ms.
- For the analytics service to span data centers, network latency between data centers must be less than 10 ms. If you want to associate an analytics service with your gateway service, and cannot meet this latency requirement, then choose one of the data centers to host the analytics service.

Cloud Pak for Integration: Cannot add an API to the Asset Repository

If you are using API Connect as a component of Cloud Pak for Integration, you cannot add an API to the Asset Repository from API Connect.

Cloud Pak for Integration: Problem importing from Asset repository when user remains inactive

If there is no user activity on the page while importing an API from the Cloud Pak for Integration Asset repository, the user might see the following error: `could not add asset, parent window missing`

Work around the issue by reloading the Import API page and then opening the Asset repository again.

Limitations to the updated schema editor for API definitions

The Definitions section of the API editor for the API Manager and API Designer UIs was updated in API Connect 10.0.6.0. However, the `OneOf`, `AllOf`, and `Enum` schema structures aren't handled properly by the UI. You can work around this issue by editing the source YAML of your API document.

API Designer with Local Test Environment (LTE) fails to log in using https://localhost with the error message "Incorrect username, password, or credentials"

If you use the API Designer with the Local Test Environment and attempt to log in using the localhost, the login fails. You can work around the issue by configuring API Designer credentials to with the local host. Complete the following steps:

1. Download and extract API Designer, then install the credentials file as explained in steps 1, 2, and 6 in Installing the toolkit.
2. Edit the designer_credentials.json file and configure the following settings:
   - `"endpoint": "https://localhost"`
   - `"manager_endpoint": "https://localhost/manager"`
   - `"client_id": Client Id`
     The client ID displays on the console when you start the LTE platform-apic-lte. For more information, see Testing an API with the Local Test Environment.
   - `"client_secret": Client Secret`
     The client secret displays on the console when you start the LTE platform-apic-lte. For more information, see Testing an API with the Local Test Environment.
3. Start API Designer and log in with the LTE using https://localhost as the Host URL (the management endpoint).

Gateway timeout when validating very large API documents with the API governance service

If you are validating very large API documents (5 MB, or 100,000 lines, or more), with all of the rulesets selected by default, the API governance service is likely to take longer than 60 seconds to run, and this can result in an HTTP 504 gateway timeout. To workaround this issue, you can take the following actions:

- Validate the API document by using only one ruleset at a time.
- Increase your component deployment profile, for example to a three replica profile. For more information, see Deployment and component profiles, and Planning your deployment topology and profiles on VMware.

New ibm-apiconnect-operator pod fails to start due existing terminating ibm-apiconnect-operator pod holding lock

The IBM APIConnect operator uses leader election (leader-for-life) to ensure that only one operator/controller pod is running/active at a time. This relies on Kubernetes garbage collection to clean up the lock when the old operator pod is deleted. The new ibm-apiconnect operator pod fails to start if an existing terminating ibm-apiconnect operator pod is still holding the lock.

If you suspect you are encountering this issue, verify it by running the following command:

```
kubectl -n <namespace> logs <new-ibm-apiconnect-pod-name> | grep "LockOwner"
```

If the lock is the problem, the log contains a message similar to the following example:

```
existing lock","LockOwner":"ibm-apiconnect-xxxxxx held by
terminating pod
```

Resolve the issue by completing one of the following options:

- Force delete the terminating pod by running the following command:

  ```
  kubectl -n <namespace> delete pod <terminating-ibm-apiconnect-pod-name> --force --grace-period=0
  ```

  Kubernetes deletes the lock when the pod is deleted.

- Remove the lock manually by running the following command:

  ```
  kubectl delete cm ibm-apiconnect-lock
  ```

API Designer might hang while activating a large imported API

When you import a large API using API Designer and attempt to activate the API in the import wizard, the process might hang. If you encounter this issue, you can work around the problem by completing the following steps:

1. On your local file system, locate the autoproduct file called API-NAME-auto-product_API-VERSION.yaml.
2. Delete the file.
3. In API Designer, edit the newly imported API and activate it by clicking the Online toggle.

In general, it is best practice to activate an API using the Online toggle or by publishing the API with the Publish option.

API Designer on Windows: APIs that use WSDL might encounter errors, or fail to activate, publish, or update.
If you activate, publish, or update a REST or SOAP API that uses a WSDL file, the operation might fail and never complete. Work around the issue by using the autopublish API feature in the API editor.

Permission restrictions in the API Designer UI
The API Designer UI currently has the following permission restrictions:

- Developers that have been given only View permissions cannot see the Test tab in the API editor. For developers to be able to see the Test tab, they must be given a different permission level. For information about the default permission levels available, see API Connect user roles.
- Users with API-Drafts permissions, but who don't have any Sandbox Catalog permissions, cannot see the Test preferences in the Sandbox Catalog. For these users to be able to see the Test preferences, they must be given the Developer or Administrator role on the Sandbox Catalog.

Deleted security requirements might remain in the API source
Security requirements that are deleted from APIs in the API Designer and API Manager UIs, might still remain in the source. To work around this issue, click the Source icon </> in the API editor, and manually remove the security requirements.

Sometimes the completion of an SFTP restore on the Management subsystem does not restore the actual data.
There is a known issue where sometimes a restore from the Management subsystem's SFTP backup succeeds but the data is not restored. If this happens, run the restore again.

Customized application view is reset to the default after upgrade if forums are also disabled
When upgrading API Connect version 10.0.5.0 or earlier to version 10.0.5.1 or later, if you have disabled forums on your Developer Portal site, and you have customized the application view, the customized application view will be reset to the default after the upgrade. To work around this issue, you can save the customized application view before running the upgrade, and then import the view into the upgraded Developer Portal.
To save the customized application view, run the following commands:

```
mkdir /tmp/tmp_config_<site-alias>
drush @<site-alias> config-get views.view.applications > /tmp/tmp_config_<site-alias>/views.view.applications.yaml
```

Where *<site-alias>* is the alias of your Developer Portal site.
To import the saved view after the upgrade, put the views.view.applications.yaml file inside a directory where it's the only file, and then run the following command:

```
drush @<site-alias> config-import --partial --source=/tmp/tmp_config_<site-alias>/
```

Cannot add comments to APIs by using the Source view in the API Designer and API Manager UIs
Comments cannot be added to APIs in the API Designer and API Manager UIs by clicking the Source icon </>, and using the hashtag symbol.

Changing Product visibility from Custom to Public doesn't automatically remove the Consumer organizations and groups
In the API Designer and API Manager UIs, changing Product visibility from Custom to Public doesn't automatically remove the consumer organizations and groups, so the Product publish will fail. To work around this issue, manually remove all of the consumer organizations and groups.

Stale cache can result in unexpected behavior in the Cloud Manager and API Manager UI
Having a stale cache in your browser can result in unexpected behavior in the Cloud Manager and API Manager UI, such as fetch errors, incorrect data being displayed, and blank pages. To work around this issue, particularly if you have just upgraded your deployment, complete the following actions:

- Reload the browser window.
- If there is still an issue, clear the browser cache and then log back in to the UI.
- Try using a private browser window.
- If possible, try a different browser type.

If issues persist, contact IBM Support.

The "Select compatible gateway services" option in Test Preferences causes a "404 POST undefined" error while testing the API
In the Test Preferences > Target gateway services setting, selecting Select compatible gateway services and choosing a specific gateway results in a "404 POST undefined" error when you test the API in the API Explorer or the Test tab.
Workaround: To avoid this problem, select the Use all compatible gateway services target gateway option instead.

Analytics command restrictions
The following `--mode analytics` commands work only when the flag `--return_format` is set to either `json` or `yaml`:

- `clustermgmt:catAllocation`
- `clustermgmt:catIndices`
- `clustermgmt:catNodes`
- `clustermgmt:catRecovery`
- `clustermgmt:catShards`
- `clustermgmt:catAliases`

The following commands don't currently work on the Toolkit CLI, as they return only `text/plain`:

- `clustermgmt:getNodesHotThreads`
- `clustermgmt:getNodesHotThreadsById`

Options menus in the Catalog might be hidden
In a Catalog, in any of the different tabs such as Consumers, or Subscriptions, when clicking on the options icon ⋮ the menu items might be hidden. To work around the issue, reload the page and the menu items will appear.

Override plan rate limits are not displayed in the Endpoint tab
Any override plan rate limits that have been added to your API for individual operations are not displayed in the API Endpoint tab in the UI. Only the plan rate limit is displayed.

Consumer rate limit notifications are not available in Version 10
The ability to configure notifications for applications so that API consumers are alerted when the usage of an API is nearing its rate limit is not available.

Configuration update mistakes cause admission webhook errors in OpenShift and Cloud Pak for Integration

In OpenShift and Cloud Pak for Integration, configuration update errors can cause the **APIConnectCluster** instance to go into the Pending state with an underlying component throwing an admission webhook error.

```
oc get apiconnectcluster -n APIC_namespace

NAME   READY  STATUS    VERSION             RECONCILED VERSION   AGE
m1     admission webhook "vmanagementcluster.kb.io" denied the request:
ManagementCluster.management.apiconnect.example.com "m1-mgmt" is invalid: [spec.databaseBackup.restartDB.accept: Invalid
value: false: databaseBackup protocol has changed (from '' to 'objstore') and requires database restart. accept restartDB
to restart database, spec.databaseBackup.restartDB.accept: Invalid value: false: databaseBackup configuration has changed
and requires database restart. accept restartDB to restart database]   Pending   10.0.1.5-3388-eus   10.0.1.5-3388-eus
2d6h
```

The 'strict' SameSite cookie causes incorrect invitations to consumer organizations

Using the 'strict' SameSite cookie might cause invitation links from emails to send users to a registration page where they are asked to create a new consumer organization instead of joining the organization they were invited to.
The workaround is to using the 'Lax' SameSite Cookie attribute.

Limitations to the OpenAPI 3.0 support

IBM API Connect supports the OpenAPI 3.0 specification, with some limitations. For information about what is supported, see OpenAPI 3.0 support.

A GraphQL API that contains a **graphql-input-type-cost** rate limit fails to publish

A GraphQL API created in releases earlier than IBM API Connect Version 10.0.3.0 might contain a **graphql-input-type-cost** rate limit, which is no longer supported. If you attempt to use the automatic activation mechanism to publish the API, or manually add the API to a Product and attempt to publish that Product, the publish operation will fail. You can resolve this problem in either of the following ways:

- Remove the rate limit definition from the OpenAPI source for the API. For example, if the source is in YAML format, remove the following lines:

  ```
  - name: graphql-input-type-cost
    operation: consume
  ```

- Edit the source for the Product and define a **graphql-input-type-cost** rate limit in all of the Plans that include the API.
  Note: You can edit only a manually created Product, not a Product that is generated by the automatic activation mechanism.

Update WSDL option is not supported in the API Designer UI

The Update WSDL option to update the configuration of an existing SOAP API from a WSDL file or a .zip archive, is supported only in the API Manager UI, or by using the developer toolkit. This option is not supported in the API Designer UI.

A Product republish, with the Preserve Subscriptions option, fails after a consumer organization group has been removed from the visibility settings

If you remove a consumer organization group from the custom visibility settings for a Product, and that group contains a consumer organization with an application that is subscribed to the Product, an attempt to republish the Product with the Preserve Subscriptions option will fail even if that consumer organization is then added to the custom visibility settings individually.

For a secured GraphQL API, GraphQL subscriptions cannot be tested by using the Test tab in the user interfaces

For a GraphQL API that is secured by client ID, GraphQL subscriptions cannot be tested by using the Test tab in the API Designer or API Manager user interfaces. The API can still be published and used in production.
You can test GraphQL subscriptions in either of the following alternative ways:

- Remove client ID security from the API, for testing purposes, then use the Test tab.
- Use an external test tool.

A published API whose assembly contains a catch block with an invalid policy will now correctly fail to republish

Previously, policies in an assembly catch block were not validated, so if an incorrect policy configuration was coded in the OpenAPI source for an API, within an assembly catch block, the API would still publish successfully. Now, policies in an assembly catch block are validated, so such an API will fail to republish and will first need to be corrected.

An existing user cannot be added to a Space

If you attempt to add an existing user to a Space, the operation cannot be completed because the Create button is not enabled. Instead, use the invitation mechanism. For details, see Managing Space membership.
Note: The invited user must use the Sign in option on the activation form, rather than completing the registration details and using Sign up.

Simultaneous editing of the same API by multiple users might result in changes being overwritten

If one user saves changes to an OpenAPI 3.0 API, another user who has the same API open in the API editor might have their changes overwritten.

An API developed for IBM API Connect Version 2018.4.1 that uses an **apim.getvariable('message.body')** function call fails in IBM API Connect Version 10

With the DataPower® API Gateway in IBM API Connect Version 2018.4.1, the type of object returned, for XML payloads, by an **apim.getvariable('*context_name*.body')** function call in a GatewayScript policy in an API assembly depends on how the variable is stored in the gateway context, as follows:

- If the variable is stored as a Buffer (because the variable data was written as an XML string), an XML Nodelist is returned provided that ***contextname*.headers.content-type** is an XML type.
- If the variable is stored as a parsed XML Document (because the variable data was written as parsed XML, either as an XML document or an XML Nodelist), an XML document is returned.

With the DataPower API Gateway in IBM API Connect Version 10 however, the same function call always returns an XML Nodelist provided that ***contextname*.headers.content-type** is an XML type. Therefore, such an API developed for Version 2018.4.1 will fail in Version 10 if it is configured to expect an XML document, and will need to be reconfigured appropriately.

The problem does not occur with such an API migrated from IBM API Connect Version 5 because, with that release, **apim.getvariable('*context_name*.body')** also returns an XML Nodelist for XML payloads, nor does it occur if you are using the DataPower Gateway (v5 compatible).

context_name could be **message**, **request**, or the name of the output from an **invoke** policy.

Validate policy limitations when GraphQL response contains a GraphQL server error

When a GraphQL response contains a GraphQL server error and no data, the assembly Validate policy generates an error on the missing data and overwrites the payload. When the response contains partial data and an error, the assembly Validate action validates the data and overwrites the payload. To work around this

limitation, use the condition **`$not($exists(message.body.errors))`** in an assembly switch condition to skip the assembly Validate policy when the response contains errors.

An OpenAPI definition that contains regular expression syntax fails validation

IBM API Connect supports the GO regular expression syntax. When you import an OpenAPI definition into the API Designer or API Manager user interfaces, or validate one with the **`apic validate`**, the validation will fail if the OpenAPI source contains unsupported regular expression syntax, with errors that include **`Does not match format 'regex'`**; for example:

```
- Must validate at least one schema (anyOf) (context:
(root).paths./example/types.post.parameters.0.schema.properties.items, line: 0, col: 0)
- Must validate one and only one schema (oneOf) (context: (root).paths./example/types.post.parameters.0, line: 46164, col:
21)
- paths./example/types.post.parameters.0.schema.properties.items.properties.pattern Does not match format 'regex'
(context: (root).paths./example/types.post.parameters.0.schema.properties.items.properties.pattern, line: 0, col: 0)
```

When scaling down a Kubernetes cluster of DataPower gateways, the cluster might enter an unrecoverable state if the peering primary instance is lost

If you are scaling down a Kubernetes cluster of DataPower gateways, you must first complete the following steps to ensure that the peering primary instance is not lost:

1. List the pods in the cluster; for example:

```
$ kubectl get pods -n apiconnect --selector
app.kubernetes.io/component=datapower,crd.apiconnect.ibm.com/instance=gwv6
NAME     READY   STATUS    RESTARTS   AGE
gwv6-0   1/1     Running   0          3h31m
gwv6-1   1/1     Running   0          3h32m
gwv6-2   1/1     Running   0          3h34m
```

2. Enter the DataPower admin CLI for gateway 0, by entering the following command and logging in at the prompt; for example:

```
$ kubectl attach -n apiconnect -it gwv6-0
```

3. Switch to the API Connect domain and enter config mode:

```
idg# switch apiconnect
idg[apiconnect]# config
Global mode
```

4. Show the gateway peering status; for example:

```
idg[apiconnect](config)# show gateway-peering-status
```

Address	Configuration name	Pending updates	Replication offset	Link status	Primary
1.2.3.1	gwd	0	18331896	ok	no
1.2.3.1	rate-limit	0	3091219	ok	no
1.2.3.1	subs	0	3150127	ok	no
1.2.3.1	tms	0	3063575	ok	no
1.2.3.2	gwd	0	18330948	ok	no
1.2.3.2	rate-limit	0	3091067	ok	no
1.2.3.2	subs	0	3149975	ok	no
1.2.3.2	tms	0	3063257	ok	no
1.2.3.3	gwd	0	18330948	ok	yes
1.2.3.3	rate-limit	0	3091067	ok	yes
1.2.3.3	subs	0	3149975	ok	yes
1.2.3.3	tms	0	3063257	ok	yes

5. For each of the configuration names, set gateway 0 to be the peering primary instance:

```
idg[apiconnect](config)# gateway-peering-switch-primary gwd
The instance is now the primary in the peer group.
idg[apiconnect](config)# gateway-peering-switch-primary rate-limit
The instance is now the primary in the peer group.
idg[apiconnect](config)# gateway-peering-switch-primary subs
The instance is now the primary in the peer group.
idg[apiconnect](config)# gateway-peering-switch-primary tms
The instance is now the primary in the peer group.
```

6. Show the gateway peering status to confirm the changes; for example:

```
idg[apiconnect](config)# show gateway-peering-status
```

Address	Configuration name	Pending updates	Replication offset	Link status	Primary
1.2.3.1	gwd	0	19067953	ok	yes
1.2.3.1	rate-limit	0	3218172	ok	yes
1.2.3.1	subs	0	3277032	ok	yes
1.2.3.1	tms	0	3189160	ok	yes
1.2.3.2	gwd	0	19067953	ok	no
1.2.3.2	rate-limit	0	3218172	ok	no
1.2.3.2	subs	0	3277200	ok	no
1.2.3.2	tms	0	3189160	ok	no
1.2.3.3	gwd	0	19069241	ok	no
1.2.3.3	rate-limit	0	3218172	ok	no
1.2.3.3	subs	0	3277508	ok	no
1.2.3.3	tms	0	3189312	ok	no

Incorrect UI behavior if API changes are not saved before creating a new API version

If you make changes to an API definition and then attempt to create a new API version without first saving your changes, you are not prompted to save your changes until after you have completed the new version creation operation. If you click OK in the prompt, your new version is created but your original changes are lost; to create your new version and retain your original changes, you should click Cancel in the prompt, then click Save to save your original changes.

Truststore and keystore settings in a shared TLS client profile are not reflected in API Manager

If you create a shared TLS client profile in the Cloud Manager user interface and assign a truststore and a keystore, these truststore and keystore settings are not reflected in that TLS client profile in the API Manager user interface and cannot be set there. Furthermore, the TLS client profile list views display the value shared for the truststore and keystore rather than the correct values. To workaround this problem, create the truststore, keystore, and TLS client profile separately for each provider organization in the API Manager user interface, then enable the TLS client profile in your Catalogs as required.

Login to the Cloud Manager or API Manager user interfaces might fail with error 431 if the browser has a large number of cookies

Attempts to login to the Cloud Manager or API Manager user interfaces might fail if the HTTP header or cookie size is larger than 32 KB, a limitation that is imposed for security reasons. To resolve this problem, either clear the browser cache and cookies, or open a private window, then retry.

The `apic cloud-settings:topology` command doesn't return a topology object

If you use the `apic cloud-settings:topology` command without a `--format` parameter, it returns only the string `CloudTopology` rather than the cloud topology. To retrieve the topology object, include the `--format` parameter, with a value of either `yaml` or `json` as required.

The `apic cloud-settings:mail-server-configured` command response is incorrect

If you use the `apic cloud-settings:mail-server-configured` without a `--format` parameter, it returns only the string `MailServerConfigured` rather than a boolean value to indicate whether an email server has been configured in the cloud settings. To retrieve the correct response, include the `--format` parameter, with a value of either `yaml` or `json` as required.

API Designer user interface might not open correctly if there are badly formed OpenAPI YAML files in the startup directory

If, when launching the API Designer user interface, the startup directory that you select contains one or more badly formed OpenAPI YAML files, the interface might fail to load correctly, with an error such as the following:

```
Cannot read property 'type' of null
```

To resolve this problem, remove any invalid OpenAPI YAML files from the startup directory, then restart the API Designer user interface.

Pagination setting is global across the API Connect user interfaces

If you set the Items per page value on any page in the Cloud Manager or API Manager user interface, that setting is then applied to all pages in both user interfaces in the same browser session. If you want to set the value separately for a specific page, open it in a private browser window. Such a setting in a private browser window is specific to that window and is lost when the window is closed.

Setting resource limits in Kubernetes can cause containers to behave oddly at run time

In Kubernetes, you can set resource limits for each container. However, limiting CPU means that the container processes might slow down if they try to use too much. Limiting memory means that the Kubernetes code kills processes that try to allocate memory that would take the container over its limit. These limits can result in odd behavior such as the containers continually trying to start a daemon process, such as nginx or node, and exiting with success immediately.

Field validation for the Client security policy is incorrect

When configuring a Client Security policy in an API assembly in the API Designer or API Manager user interfaces, there is the following incorrect validation behavior:

- The ID Name field is required, but the API definition can be saved without entering a value in the field.
- The Secret Name field is required only when the Secret Required option is selected, but the user interface indicates that the Secret Name field is required regardless. Furthermore, when the field is required, the API definition can be save without entering a value.
- If the Authenticate Client Method is set to Third party, the User Registry Name field is required, but the API definition can be saved without entering a value in this field.

Requests that take longer than the value of the nginx timeout cause a 409 error

Requests that take longer than the value of the `nginx` timeout can cause a 409 error, such as:

```
Another request is operating on portal-subsystem-03729230-4df7-4419-94c9-e7691b616382 with the same name,
please try again.
```

The error occurs because the ingress controller is sending a repeat request when the previous one timed out. Your request will still continue processing in the background.

Adding members to a provider organization might fail

When adding members to a provider organization, the Cloud Manager user interface lists the current owner and members as well. If existing members are selected, the add action will fail.

Upgrading with new certificates breaks analytics ingestion

If the analytics subsystem certificates are modified after installation (by using the **apicup certs set** command , followed by the **apicup install** command to deploy the change to the cluster), the analytics ingestion ingress will no longer be recognized by the Gateway. The analytics service must be re-registered in the Cloud Manager interface so that the new certificates are recognized.

User interfaces are not supported in Microsoft Edge

The API Manager and Cloud Manager user interfaces are not supported in the Microsoft Edge web browser. To work in the user interfaces, use a different browser.

New gateways cannot connect to existing gateways after the gateway peering certificates are changed

Changing the gateway peering SSL certificates after gateway installation causes new gateways to be unable to connect to existing gateways, resulting in an outage. A full restart of the gateway StatefulSet (by deleting all the StatefulSet pods) is required for the gateways to come back online.

No option to bulk delete APIs or Products

In the API Designer and API Manager user interfaces, there is currently no option to delete multiple APIs or Products in a single operation; in the user interfaces, APIs and Products must be deleted individually. However, you can bulk delete APIs and Products by using the REST API or CLI interfaces.

Cannot publish an API that has duplicate security definition entries

The API Designer and API Manager user interfaces allow you to add duplicate security definitions to an API. However, attempts to publish the API will fail with OpenAPI validation errors. Ensure that the security definitions in an API are unique.

Kubernetes might excessively evict pods

In Kubernetes, if insufficient memory, CPU, or storage resources are provided then pods are evicted randomly. To avoid this problem, allocate sufficient resources to the pods. In addition, there are known issues with log rotation in Kubernetes that are documented here: https://github.com/kubernetes/kubernetes/issues/59902. The lack of log rotation can cause logs to grow, limited only by the amount of storage on the node, eventually causing pods to restart. Therefore ensure that appropriate log levels are configured for all API Connect components.

You may also follow the instructions described here https://success.docker.com/article/how-to-setup-log-rotation-post-installation to set the maximum size of the log before it is rolled (max-size) and the maximum number of log files that can be present (max-files). More information about the Docker JSON File logging driver is available here: https://docs.docker.com/config/containers/logging/json-file/.

Logging in to the API Connect user interfaces fails when using the Safari web browser
If you are using the Safari web browser and a Basic Authorization header exists for the same DNS domain in which API Connect is running, attempts to log in to the API Connect user interfaces, or to sign up by using an activation link, fail. To avoid this problem, use an alternative web browser.

Endpoints cannot be changed by using APICUP after they have been configured in Cloud Manager
The changing of endpoints with APICUP after they have been configured in Cloud Manager is not supported. Any such endpoint changes will not be propagated to a running deployment.

An OAuth provider fails if the resources that it references aren't enabled in the Catalog
If you enable an OAuth provider in a Catalog then any resources that it references, such as API user registries or TLS client profiles, must be enabled in the same Catalog; if not, then although the OAuth provider might publish successfully it will fail at run time. For information on enabling resources in a Catalog, see Creating and configuring Catalogs.

Redact conditions within `switch`, `operation-switch`, or `if` policies might not execute after converting to DataPower API Gateway
If an API Connect v5-compatible `redact` policy is found within a `switch`, `operation-switch`, or `if` policy, the migration utility does not move the `redact` policy to the beginning or end of the assembly. The difference in the response between API Connect v5 and DataPower API Gateway may prevent data from being redacted in the DataPower API Gateway.
For example, if an assembly includes a `switch` policy containing four redact conditions followed by an `invoke` policy, each redact condition redacts the response data. After porting to the API Gateway, the redact conditions remain inside the `switch` policy and target the `message.body` property for redaction. These redactions fail to execute because the `message.body` property has not yet been retrieved by the `invoke` policy. To correct this problem, you must move the `invoke` policy before the `switch` policy in the assembly.

Redact on invalid XPath fails after converting to DataPower API Gateway
`Redact` on invalid XPath fails after converting to DataPower API Gateway. ApplicationManagement Unit (AMU) version 10.0.8.0-R0 support the conversion of the Redactpolicy, but only to Redact version 1.5.0, not 2.0.0.

Numerical Handling in YAML Configurations and Precision Constraints in API Manager UI

- In the API Manager UI YAML configurations, numbers in exponential notation (for example 1e20) are handled differently based on their exponent value. Numbers with an exponent less than or equal to 20 are converted to their full integer form (for example 1e20 becomes 100,000,000,000,000,000,000) for display and processing. Numbers with an exponent greater than 20 stay in exponential notation (for example 1e21). Numbers that exceed the range of integers that are supported by DataPower JSON schema validation (-9,007,199,254,740,992 to 9,007,199,254,740,992) result in validation errors or unexpected behavior.
- JavaScript's inherent precision limitations truncate floating-point numbers to approximately 17 significant digits. For example:
  - Input: 0.123456789012345678901234567890
  - Processed Value: 0.12345678901234568

API Connect concepts

To help you get started, read about the API Connect concepts and obtain a high level understanding of the API management solution.

- **Who does what in API Connect?**
  Review the different functions that users can perform in API Connect, the typical set of tasks that is performed by each type of user, and the documentation most often used for each task.
- **Packaging strategy and terminology in API Connect**
  API Connect uses a proprietary packaging strategy for creating and publishing collections of APIs.
- **API Connect components**
  The API Connect components provide a unified user experience across the API lifecycle. Changes in one stage of the API lifecycle are automatically reflected in the other components of API Connect.
- **API Connect support**
  If you experience a problem with IBM API Connect that you cannot resolve, you can check the IBM Support website for the most recent technical bulletins and fixes. Otherwise, you can contact IBM Support.

Who does what in API Connect?

Review the different functions that users can perform in API Connect, the typical set of tasks that is performed by each type of user, and the documentation most often used for each task.

Systems administrators

If you deploy API Connect on premises, then your company manages the systems. Because API Connect comprises multiple servers even in an on-premises deployment, the collection of servers and services is referred to as a (local) cloud. This is unrelated to any servers and systems that are deployed in IBM® Cloud.

In an on-premises deployment, there are two roles for managing your deployment:

- Cloud owner: There is one cloud owner for a deployment, and that person adds other people to the server management team.
- Cloud administrator: Your deployment needs at least one cloud administrator; your company will probably assign multiple people to perform this role. Cloud administrators manage the deployment and configuration of API Connect servers and software.

In the API Connect documentation, cloud owners and administrators are primarily interested in the following sections, which introduce concepts and explain how to deploy, maintain, and configure the components of an on-premises deployment.

Users

At the highest level, API Connect users belong to organizations, which are groups of people. A *provider organization* (often shortened as *p-org*) is a group of people who create, publish, and maintain APIs that are then used by people in a *consumer organization*. Consumers develop their own applications that call the APIs created by providers. A single customer can create multiple provider organizations and consumer organizations. For example, different divisions within a large company might work with different technologies and create entirely different sets of APIs, so it makes sense to group them into different p-orgs. Each provider organization publishes their APIs to a Developer Portal that uses consumer organizations to manage the customers who use those APIs.

At a minimum, you need one provider organization if you want to publish and manage APIs with API Connect, and one consumer organization for each customer.

Provider organization

A provider organization performs many tasks during the lifecycle of an API, from developing, publishing, and maintaining APIs to managing the membership of the organization itself. Each p-org can be as large or as small as needed. A large company might create a p-org for each product team, or for each department but a small company might use a single p-org.
A person can be a member of multiple provider organizations and receive a different set of permissions for each. When the user logs in to API Connect, they select the organization whose resources they will use, and receive the appropriate permissions for that organization for the duration of the session.

The following roles are commonly associated with a provider organization but are not necessarily represented by different people. In a small company, one person might perform all of the API maintenance tasks while in a larger company, several people might take on separate roles.

- Organization Owner: Every provider organization requires one owner to ensure that a user account is associated with the organization. The organization owner has full access to all of the p-org's resources (APIs, Products, Catalogs, and so on) and role cannot be deleted. The organization owner can add people to the organization manager role.
- Organization Manager: Maintaining the organization account is the job of the organization manager. In a large company, several people might share this role. Organization managers add *members* to provider organizations and assign them the permissions needed to perform their jobs. Organization owners and managers typically use the docs on administering provider orgs and administering members and roles.
- API Developer: In API Connect, an API developer creates new APIs and updates existing APIs as needed. The API developer can configure *policies* that define security restrictions, logging rules, and quotas that control access to your company's resources. The API developer might be assigned to work with a specific *Catalog* that manages a subset of APIs, or they might receive access to all of the p-org's Catalogs and the *Spaces* within each. API developers are usually most concerned with documentation related to developing APIs, managing API settings, and authoring policies for APIs.
- API Administrator: After an API developer creates a set of APIs, the API administrator manages the distribution. The API administrator defines *Plans* that determine access to the APIs, collects related APIs into *Products*, and publishes them to the consumer Developer Portals. To complete these tasks, the API administrator uses documentation focused on managing API syndication and working with Products.
- Product Manager: A product manager controls access to the Developer Portal where customers subscribe to APIs and then tracks API usage and performance. For each customer, the product manager creates a consumer organization, assigns a customer representative as the owner, and manages the relationship between the provider organization and each consumer organization. The product manager can customize the appearance of Developer Portal for their p-org as well as provide forums and blogs for their consumers. The product manager uses the API Connect Analytics service to track API usage and performance so that the p-org knows when APIs should be updated or retired. The product manager typically uses documentation on administering consumer organizations, using the Developer Portal, and reviewing API analytics.

Consumer organization

A consumer organization creates applications that use the APIs that are developed by provider organizations. Each provider's APIs are made available to each consumer organization in the API Connect Developer Portal. Members of a consumer organization typically perform two functions:

- Consumer Organization Owner: The consumer organization owner also manages the organization by inviting other members and assigning permissions to each. This role additionally has permissions to customize the Developer Portal where members access APIs that the organization is subscribed to.
- Application Developer: Create applications that invoke APIs shared through the Developer Portal.

The only API Connect feature that API consumers use is the Developer Portal, which is managed by the API provider. There is no need for consumers to read the API Connect documentation.

- **API Connect user roles**
  The IBM API Connect solution provides an infrastructure, tools, and facilities that allows users to create, manage, and stage APIs. The ability to perform tasks in the API Connect user interfaces is controlled through user roles, and the permissions that are assigned to those roles.

API Connect user roles

The IBM® API Connect solution provides an infrastructure, tools, and facilities that allows users to create, manage, and stage APIs. The ability to perform tasks in the API Connect user interfaces is controlled through user roles, and the permissions that are assigned to those roles.

The roles described here are the default API Connect roles. In the API Manager user interface, you can create custom roles; for more information, see: Creating custom roles. You can also create custom roles in the Developer Portal user interface.

The following sections describe the roles and permissions for each of the API Connect user interfaces:

- User roles in the Cloud Manager UI.
- User roles in the API Manager UI.
- User roles in the Developer Portal UI.

User roles and permissions in the Cloud Manager UI

The following table describes the Cloud Manager UI user permissions as configured in the base product. Certain roles can edited as indicated In Table 2, and custom roles can be created. For instructions on how to create custom roles for the Admin organization (Cloud Manager users), see Creating roles in the admin organization.

Table 1. Cloud Manager UI permissions

Permission	Action	Meaning
Cloud Settings	View	View all items on the Cloud Manager > Settings menu (except Roles)
	Manage	Add, update, and delete all items on the Cloud Manager > Settings menu (except Roles)
Member	View	View members on the members list located at Cloud Manager > Members

Permission	Action	Meaning

	Manage	Add and invite members from Cloud Manager > Members
		Note: By default, a user with Member > Manage permission can assign, to themselves or to another user, any role with any permission regardless of the permissions that they themselves have. However, you can apply a restriction such that, for a user to assign a role, they must themselves have at least all of the permissions that are applied to that role. To apply that restriction, complete the following steps:
		1. Log in to your management server from the toolkit CLI as a member of the cloud administration organization; for details, see Logging in to management server.
		2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):
		`apic cloud-settings:update --server mgmt_endpoint_url -`
		where *mgmt_endpoint_url* is the platform API endpoint URL.
		3. Enter the following data, followed by a new line:
		`restrict_member_manage_permission: true`
		4. Press `CTRL D` to terminate the input.

Org	View	Org:View is a permission assigned to all Roles in Cloud Manager. It does not provide access to any functionality. It allows a user to activate their membership. It is the only permission in the Member role.
Provider-Org	View	View the list of provider organizations at Cloud Manager > Provider Organizations
	Manage	Add, edit, and delete provider organizations and invite owners from Cloud Manager > Provider Organizations
Settings	View	View the items on the Cloud Manager > Resources menu plus Roles located at Cloud Manager > Settings > Roles
	Manage	Add, edit, and delete the items on the Cloud Manager > Resources menu plus Roles located at Cloud Manager > Settings > Roles
Topology	View	View the items on the Cloud Manager > Topology menu
	Manage	Add, edit, and delete the items on the Cloud Manager > Topology menu
Analytics	View	View items on Cloud Manager > Analytics, and also create, update, duplicate, delete, share, and unshare saved queries.

The following table lists the various Cloud Manager UI roles and the permissions assigned to them.

Table 2. Cloud Manager UI roles

Role	Permissions	Actions	Default role provides access to	Notes
Owner	All permissions	All actions	All menus	Cannot be modified or deleted.
Administrator	All permissions	All actions	All menus	Includes analytics:view.
Member	Org	View	Membership activation only	Cannot be modified or deleted. Member role is automatically assigned to all users when they activate their membership from the invitation. It allows them to activate but does not provide access to any menus.
Organization Manager	Org	View	N/A	Can be modified and deleted.
	Provider-Org	View, Manage	Provider Organizations menu	
Topology Administrator	Org	View	N/A	Can be modified and deleted.
	Topology	View, Manage	Topology Menu	
	Settings	View, Manage	Resources menu plus Settings > Roles	
Viewer	All permissions	View	All menus, view only	Cannot be modified or deleted.

User roles and permissions in the API Manager UI

The following tables describe the API Manager UI user permissions.

A user with Roles permission can change the permission assignments, and can create custom roles; for more information, see Creating custom roles in the section, Managing your APIs.

Note: In API Manager, the Owner role has full access and cannot be edited or deleted. All other roles, including custom roles, can be deleted. If you delete a role, users lose that role. If a user loses that role, their account remains in API Manager, enabling you to add a role to the user at a future date.

Table 3. Organization permissions

Permissions	Action	Permits the member to
Member	View	View organization's members

Permissions	Action	Permits the member to

	Manage	Manage organization's members
		Note: By default, a user with Member > Manage permission can assign, to themselves or to another user, any role with any permission regardless of the permissions that they themselves have. However, you can apply a restriction such that, for a user to assign a role, they must themselves have at least all of the permissions that are applied to that role. To apply that restriction, complete the following steps:
		1. Log in to your management server from the toolkit CLI as a member of the cloud administration organization; for details, see Logging in to management server.
		2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):
		`apic cloud-settings:update --server mgmt_endpoint_url -`
		where *mgmt_endpoint_url* is the platform API endpoint URL.
		3. Enter the following data, followed by a new line:
		`restrict_member_manage_permission: true`
		4. Press **CTRL D** to terminate the input.

Settings	View	View an organization's configuration settings, including roles, TLS profiles, and user registries. View configuration settings for a Catalog or Space, including policies and OpenAPI extensions.
	Manage	Manage an organization's configuration settings, including roles, TLS profiles, and user registries. Manage configuration settings for a Catalog or Space, including policies and OpenAPI extensions.
Topology	View	Same permissions as **`Settings: View`**.
	Manage	Same permissions as **`Settings: Manage`**.
Org	View	View an organization
Product-Drafts	View	View draft APIs and Products
	Edit	View draft APIs and edit draft Products
Api-Drafts	View	View draft APIs
	Edit	Edit draft APIs and view draft Products
Product	View	View Products
	Stage	Stage Product
	Manage	Manage Product
Product-Approval	View	View Product lifecycle changes
	Stage	Approve the staging of a Product
	Publish	Approve the publishing of a Product
	Supersede	Approve the superseding of a Product
	Replace	Approve the replacement a Product
	Deprecate	Approve the deprecation of a Product
	Retire	Approve the retiring of a Product
Consumer-Org	View	View consumer organization and developers
	Manage	Manage consumer organization and developers
App	View	View both production and development applications.
	Manage	Manage both production and development applications. A member with this permission can also request the promotion of a development app to a production app. This request triggers a task that needs approval by a member with the App-approval Manage permission.
App-Dev	Manage	Same permissions as **`Settings: Manage`**.
App-Approval	View	View application approvals, for requests to promote a development app to a production app.
	Manage	Manage (Approve or Decline) requests for approval to promote a development app to a production app.
Subscription	View	View application Plan subscriptions that have been created by application developers in the Developer Portal.
	Manage	Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.
Subscription-Approval	View	View application Plan subscription approvals.
	Manage	Manage (approve or decline) application Plan subscriptions.
Consumer-Onboard-Approval	View	View consumer onboard approvals.
	Manage	Manage (approve or decline) consumer onboard approvals.
Api-Analytics	View	View analytics data, as well as access and apply saved analytics queries.
	Manage	In addition to the view permissions, the user can create, update, duplicate, delete, share, and unshare saved analytics queries.
Child	View	At the provider organization level, view Catalogs in the provider organization. At the Catalog level, view Spaces in the Catalog.
	Create	At the provider organization level, create Catalogs in the provider organization. At the Catalog level, create Spaces in the Catalog.
	Manage	At the provider organization level, manage Catalogs in the provider organization. At the catalog level, manage Spaces in the Catalog. Management tasks including deleting a Catalog or Space, or transferring ownership of a Catalog or Space.

A user with Settings > Manage permission can change the permission assignments, and can create custom roles; for more information, see Creating custom roles in the section, Managing your APIs.

Table 4. Default API Manager UI roles and the default permissions assigned to those roles.

Role	Role description	Permissions	Actions

Role	Role description	Permissions	Actions
Organization Owner	A provider organization owner has the full set of access permissions to API Connect functions, and also commission APIs and tracks their business adoption.	All permissions	All actions.
Administrator	A provider organization administrator has, by default, the full set of access permissions to API Connect functions, and also commission APIs and tracks their business adoption.	All permissions	All actions.
API Administrator	API administrators manage the lifecycle of APIs and publish APIs for discovery and use.	All permissions	All actions except cannot manage the following permissions: Member, Settings, Topology, and Child.
Community Manager	A community manager manages the relationship between the provider organization and application developers, provides information about API usage, and provides support to application developers.	Member	View
		Settings	View
		Topology	View gateway services or portal services at the provider organization.
		Org	View
		Drafts	View, Edit
		Product	View
		Product-approval	View
		Consumer-org	View, Manage
		App	View, Manage
		App-dev	Manage
		App-approval	View, Manage
		Subscription	View, Manage
		Subscription-approval	View, Manage
		Consumer-onboard-approval	View, Manage
		Api-analytics	View, Manage
		Child	View
Developer	API developers design and develop APIs and applications for the provider organizations to which they belong. Note: The Developer role allows the creation of Products and APIs, and the staging and publishing of Products to a Catalog or Space, when assigned to a user at the provider organization level--but not when assigned to a user who is a member only of a Catalog or Space within a provider organization. A Developer in a Catalog or Space can manage Products that are staged or published to the Catalog or Space.	Member	View
		Settings	View
		Topology	View gateway services or portal services at the provider organization.
		Org	View
		Drafts	View, Edit
		Product	View, Stage, Manage
		Product-approval	View, Stage, Publish, Supersede, Replace, Deprecate, Retire
		Consumer-org	View
		App	View, Manage
		App-dev	Manage
		App-approval	View, Manage
		Subscription	View, Manage
		Subscription-approval	View, Manage
		Api-analytics	View, Manage
		Child	View, Create
Member	Member of a provider organization	Org	View
Viewer	Viewer of a provider organization	Member	View

Role	Role description	Permissions	Actions
		Topology	View gateway services or portal services at the provider organization.
		Org	View
		Drafts	View
		Product-approval	View
		Consumer-org	View
		App	View
		App-approval	View
		Subscription	View
		Subscription-approval	View
		Api-analytics	View
		Child	View

Note: In API Manager, the Organization Owner role has full access and cannot be edited or deleted. All other roles, including custom roles, can be deleted. If you delete a role, users lose that role. If a user loses that role, their account remains in API Manager, enabling you to add a role to the user at a future date.

User roles in the Developer Portal UI

The following table describes the various Developer Portal UI roles that relate to working with APIs and applications. In addition, you can create custom roles for the Developer Portal site itself.

Table 5. Developer Portal UI roles

Role	Role Description	Permission	Actions
Owner	Owns and administers the app developer organization	Organization member	View, Manage
		Organization settings	View, Manage
		Organization view	View
		Consumer product	View
		Consumer app	View or Manage production or development applications
		Consumer app-dev	Manage development applications
		Consumer subscription	View or Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.
		Consumer app-analytics	View application analytics
Administrator	Administers the app developer organization	Organization member	View, Manage
		Organization settings	View, Manage
		Organization	View
		Consumer product	View
		Consumer app	View, Manage production or development applications
		Consumer app-dev	Manage development applications
		Consumer subscription	View or Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.
		Consumer app-analytics	View application analytics
Developer	Builds and manages apps in the developer organization	Organization member	View
		Organization settings	View
		Organization	View
		Consumer product	View
		Consumer app	View, Manage production or development applications
		Consumer app-dev	Manage development applications
		Consumer subscription	View or Manage the application Plan subscriptions that have been created by application developers in the Developer Portal. The Manage permission includes ability to migrate a subscription to another plan.

Role	Role Description	Permission	Actions
		Consumer app-analytics	View
Member	Member of the app developer organization	Organization	View
Viewer	Viewer of the app developer organization	Organization member	View
		Organization settings	View
		Organization	View
		Consumer product	View
		Consumer app	View applications
		Consumer production-app	View production applications
		Consumer app-analytics	View application analytics

Note: A user called admin is created automatically, with full administrator access to the Developer Portal site. The admin user can view Products and APIs but has no access to use APIs. The admin user assumes the email address of the owner of the provider organization associated with the Developer Portal.

Packaging strategy and terminology in API Connect

API Connect uses a proprietary packaging strategy for creating and publishing collections of APIs.

The packaging strategy supports API providers in meeting the requirements of the API consumers. An understanding of the concepts and terminology behind the packaging strategy is required before developing and deploying APIs using IBM® API Connect.

The following sections describe the concepts and terminology behind the packaging strategy for IBM API Connect:

- APIs
- Plans and Products
- Catalog and Spaces
- Organizations and users
- Sample provider organization with two Catalogs

APIs

An Application Programming Interface (API) is an industry-standard software technology. An API is a set of routines, protocols, and tools for building software applications. An API specifies how software components interact and provides quick access to common assets and processes. APIs can be public (such as offered on GitHub), can require client credentials, or can be kept private within an application. Thus, APIs are classified as external (public), partner (protected), or internal (private), based on how they are consumed.

An API is composed of operations, called methods, which are offered in one of the following styles in API Connect:

- A REST API is structured according to the principles of Representational State Transfer. REST APIs use HTTP or HTTPS requests to PUT, GET, POST, and DELETE data (also referred to as CRUD operations). REST identifies resources using URIs. Data can be described in a variety formats (XML, HTML, JSON, TXT, etc.), with JSON being the popular choice. REST APIs specify MIME (Multipurpose Internet Mail Extensions) types. REST is platform- and language-independent and works across firewalls using HTTPS. REST APIs leverage HTTP standards for security, caching, and status codes. HTTP clients and servers are available for all major programming languages and operating system/hardware platforms. REST implementations are easily scaled due to use of HTTP and browsers as a uniform interface.
- A SOAP (Simple Object Access Protocol) API is a web service that is exposed as an API. SOAP interfaces are described in WSDL (Web Services Description Language) format. The WSDL is an XML document describing the structure for headers, messages, URL endpoints, and datatypes used to access a web service. SOAP is considered more secure than REST as it supports WS-Security as well as SSL. SOAP also contains WS-Reliable Messaging for reliability, rather than relying on retrying the operation (as does REST). SOAP requires a client application and is better suited for enterprise applications that require secure transactions.

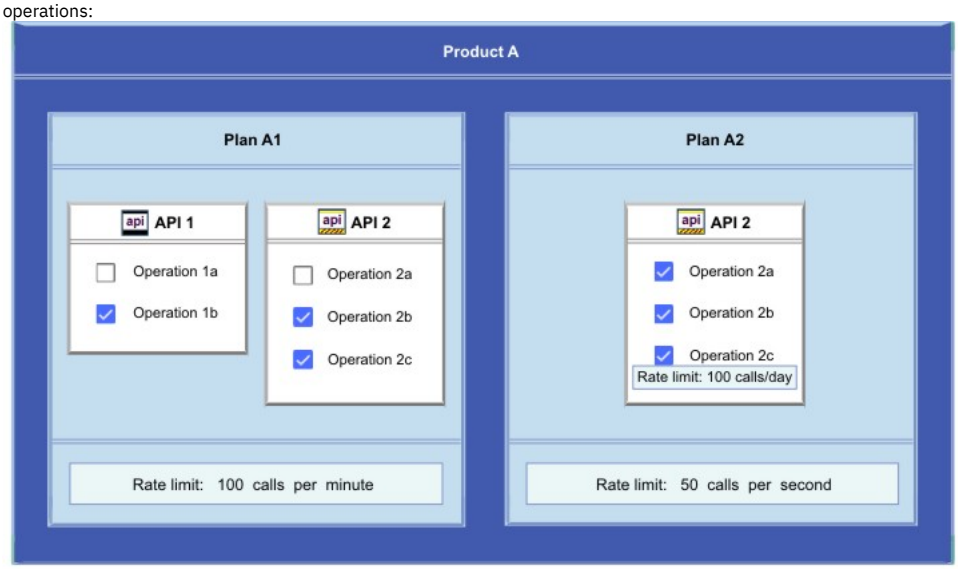
APIs can be versioned and packaged into multiple Products for distribution to API consumers on the Developer Portal. For information about creating and managing APIs, see Developing your APIs and applications and Managing your APIs.

Plans and products

Plans and products are proprietary packaging constructs that are unique to API Connect. API providers use products to offer one or more APIs to the application developers who will consume the APIs (API consumers). The providers use Plans to control access to APIs and to manage API usage. Products are packages that contain both the APIs and the accompanying Plans. See Working with Products.

To make an API available to an application developer, it must be included in at least one product and at least one plan.

Plans perform the following functions:



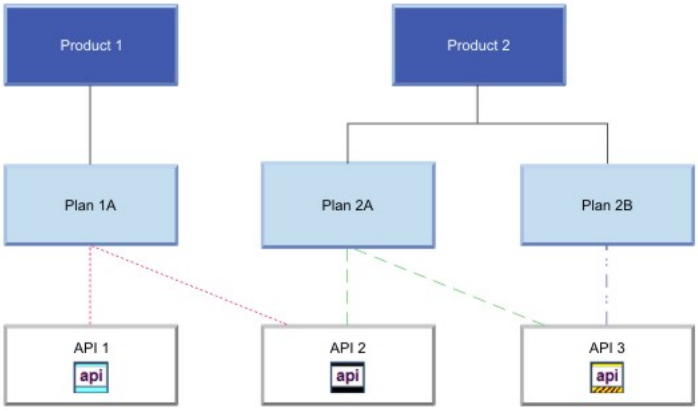
- Control which APIs an application developer can use
- Make available a collection of operations from one or more APIs
- Apply rate limits to APIs to differentiate between offerings
- Implement different rate limits to specify how many requests a consuming application is allowed to make during a specified time interval

A rate limit can be implemented as a default rate that is shared across all operations in a plan, or can be set for specific operations of an API. Plans can use differing rate limits to provide different levels of service to API consumers. For example, a "Demo Plan" might enforce a rate limit of ten calls per minute, while a "Full Plan" might permit up to 1000 calls per second.

A product in API Connect bundles a set of APIs and Plans into one offering that is intended for a particular use. You can create plans only within products, and these products are then published in a Catalog. The following rules apply for the relationship between products and plans:

- A plan can belong to only one product.
- A product can have multiple plans that each contain a different set of APIs.
- A plan in one product can share APIs with plans from any other product.

Multiple plans within a single product provide different levels of performance for the same offering. For example, a product can include a "Demo Plan" that makes a single API available, and a "Full Plan" that makes several APIs available.
The following diagram illustrates how plans can be used to make operations from one or more APIs available, and to set rate limits on both plans and individual operations:



The diagram illustrates the following concepts:

- Product A contains two APIs and two plans.
- Both APIs are included in Plan A1.
- Plan A2 includes only API 2, which is also included in Plan A1. Operation 2a for API 2 is excluded from Plan A1. All operations in API 2 are included in Plan A2.
- Different rate limits are set for the two plans at the plan level. For API 2 in Plan A2, a rate limit is also set specifically for Operation 2c to override the rate limit set at the Plan level.

Products are used to manage the lifecycle of the APIs they contain. The states in the Product lifecycle include draft, staged, published, deprecated, and retired. A product in draft state is moved to the staged state when it is staged to a *Catalog*. A product moves to the published state when the product is published. The APIs in a product become accessible to API consumers when the product is in the published state and they then become visible on a *Developer Portal*. After a product is published, application developers can use the Developer Portal to gain access to its APIs by registering applications to one or more plans in the product.

The following diagram illustrates the hierarchy of Products, Plans, and APIs.

For more information about managing the lifecycle of products, see Working with Products in the API Manager.

Catalogs and Spaces

A Catalog contains a collection of products. Catalogs are staging targets through which products (together with the accompanying plans and APIs) are published on a Developer Portal. Catalogs are used to separate products and APIs for testing before publishing them on a Developer Portal. In a typical workflow, an API provider uses a development Catalog when developing and testing APIs, and uses a production Catalog for publishing APIs that are ready for external use. Each Catalog has an associated Developer Portal for exposing the published products. A Catalog includes runtime capability through an associated gateway service that handles any API requests for the APIs in that Catalog.

API Connect includes a syndication feature that enables API providers to partition a Catalog into multiple staging targets (or *Spaces*) for API development purposes. Each API provider development team can use its own dedicated Space to manage its products independently of other teams. A Space has its own set of capabilities relating specifically to the products and APIs that are created and published to that Space. Products and APIs in all Spaces in a given Catalog are published to the same Developer Portal. Spaces are not visible on the Developer Portal. Application developers who consume the APIs on the Developer Portal are unaware of the Space configuration used by the API Developers. On the Developer Portal, the APIs are seen as a coordinated offering within a Catalog.

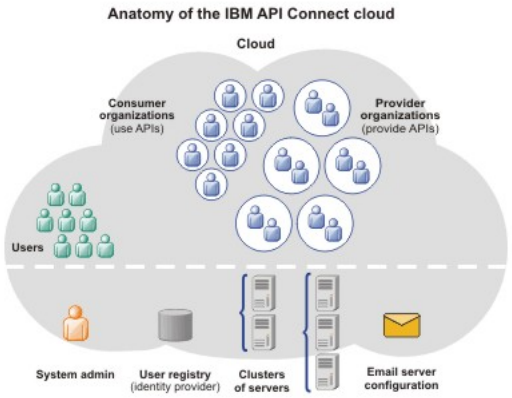
For more information about Catalogs and Spaces, see Working with Catalogs and Using syndication to partition Catalogs into Spaces.

Organizations and users

In the context of API Connect, there are two types of organizations: provider and consumer. An organization can encompass a project team, department, or division.

A provider organization owns APIs, and associated Plans and Products, and can additionally own *provider* applications that are called by APIs. To complete the various functions in the API lifecycle, a provider organization assigns responsibilities for certain tasks. Some standard responsibilities within a provider organization include:

- A provider organization owner who has the full set of access permissions to API Connect functions, and can also commission APIs and track their business adoption.
- API developers who design and develop APIs and applications for the provider organizations to which they belong.
- An administrator who manages the lifecycles of APIs and publishes APIs for discovery and use.
- A "community" manager who manages the relationship between the provider organization and application developers, provides information about API usage, and provides support to application developers.



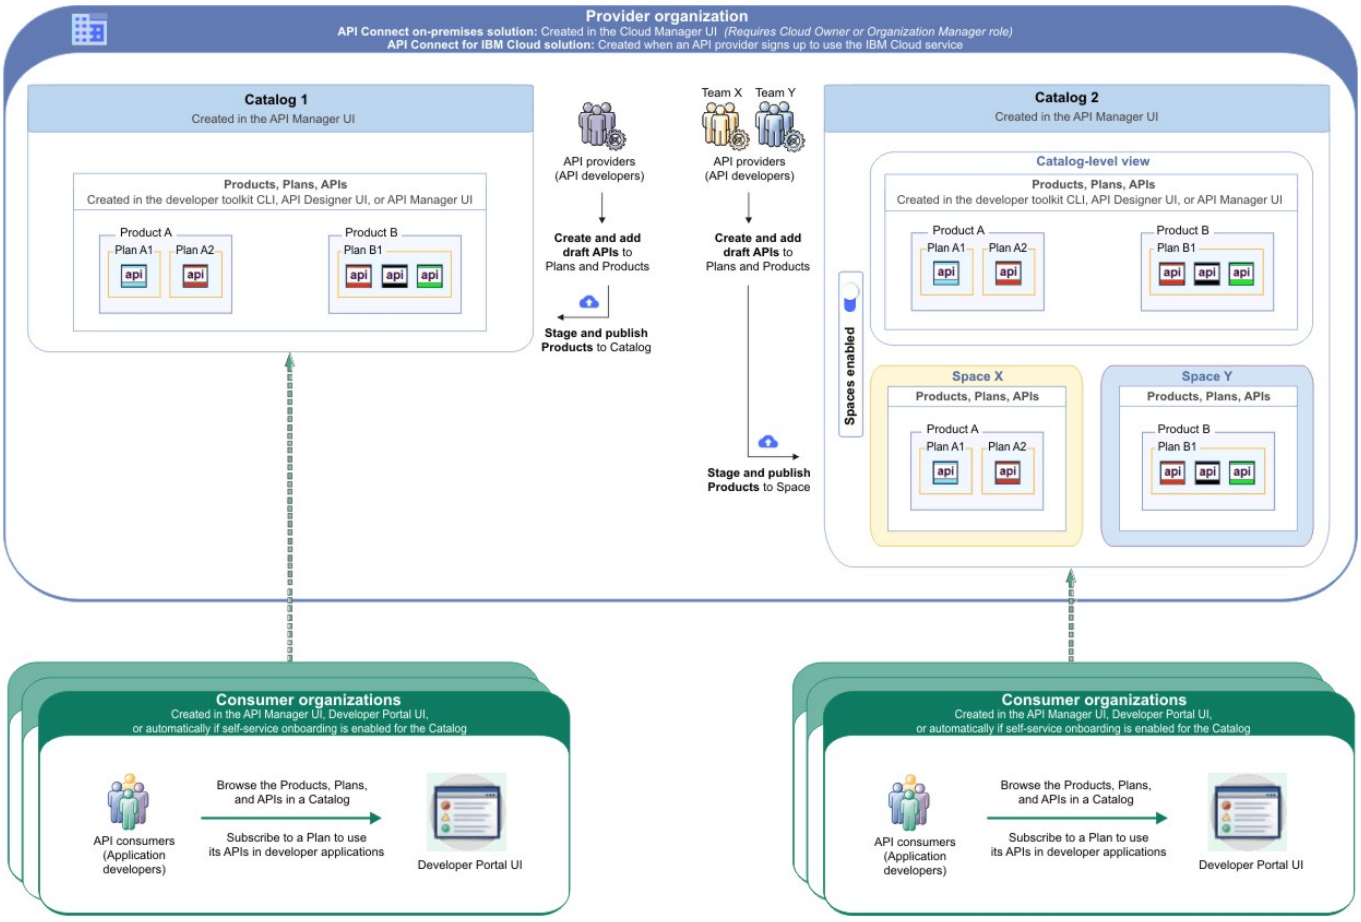
A consumer organization owns only *developer* applications, and consumes the APIs and applications produced by the provider organization. Standard responsibilities within a consumer organization include:

- A consumer organization owner who adds application developers to the consumer organization, views the Products and APIs that the provider organization has made available on the Developer Portal, and subscribes to APIs to use them in applications.
- Application developers who view the Products and APIs that the provider organization has made available on the Developer Portal, and subscribe to use these APIs in applications.

The provider and consumer organization responsibilities map to *roles* within API Connect. Some roles are independent of an organization; for example, an administrator who manages the cloud infrastructure and keeps the system running. For information about the full set of defined roles and access permissions, see API Connect user roles.

Users have an existence in the API Connect ecosystem that is independent of an organization. A user can be a member of more than one provider or consumer organization.

There can be multiple provider organizations in one API Connect cloud, to provide an API development environment for each line of business of an enterprise. The API Connect cloud is a collection of servers that comprise an API Connect installation, including the configuration information and metadata that they contain. The cloud infrastructure is shared by all organizations, and managed independently of them (by a cloud or system administrator). The following diagram shows the relationship between the provider organizations, consumer organizations, and users. The clusters shown are logical groupings of servers with the same capability.



For more information about organizations, see Administering provider organizations and Administering consumer organizations.

Sample provider organization with two Catalogs

The following diagram shows an example for how APIs, Plans, Products, Catalogs, and Spaces fit within provider and consumer organizations. In this example, two Catalogs are created in the provider organization to act as staging targets for different sets of requirements.

- Catalog 1 does not require separation of the Products for use by individual provider development teams, and so does not have Spaces enabled. API developers with access to this Catalog create draft APIs, and stage and publish them as Products to the Catalog. Several consumer organizations are granted permission to explore, discover, and use the published Products and APIs. In each of the consumer organizations, the published Products and APIs from Catalog 1 are exposed on a single Developer Portal.
- Catalog 2 is partitioned into two Spaces (X and Y) so that two provider development teams can manage their Products independently. These teams stage and publish their APIs (as Products) separately to the individual Spaces, to make them accessible to application developers in multiple consumer organizations. In each of the developer organizations, the published Products and APIs from both Spaces are exposed in the same Developer Portal, and application developers who access this portal will see the APIs from both Spaces as a coordinated offering.

- **Understanding rate limits for APIs and Plans**
  In API Connect, you can configure rate limiting on APIs and Plans to manage network traffic and API usage.

Understanding rate limits for APIs and Plans

In API Connect, you can configure rate limiting on APIs and Plans to manage network traffic and API usage.

What are rate limits and burst limits?

A rate limit is the maximum number of calls you want to allow in a particular time interval. Setting rate limits enables you to manage the network traffic for your APIs and for specific operations within your APIs. API Connect supports two types of rate limiting:

Rate limit

Rate limits operate using a fixed time interval (for example, an hour or a day) and are applied consistently based on the start of that interval. For example, if the interval is one hour, the limit will be enforced starting from the top of the hour, regardless of when the first request is made during that hour. If the rate limit is set to 1000 requests per hour, the system will allow up to 1000 requests during the period from 00:00 to 01:00, 01:00 to 02:00, and so on. The request count resets at the top of each hour. Rate limits are designed to manage and control the flow of requests over a specific period, ensuring that the system does not become overwhelmed by too many requests in a fixed time frame.

A specified number of calls to be accepted within a defined time period; for example, 100 calls per minute. In API Connect, rate limits can be defined as unlimited, or with a specified number of calls per second, minute, hour, day, or week.

Rate limits can be "hard" (enforced) or "soft". If the rate limit is hard and a call exceeds the limit, then the call is aborted and an error is returned. A soft rate limit allows the call to complete but logs a warning message. When a hard rate limit is reached, no more calls are accepted from that customer until the beginning of the next time period. For example, you might want to permit a total of 1000 calls per hour (rate limit). If a customer makes 1000 calls in the first 10 minutes, they cannot complete any more calls until the hour has expired.

Burst limit

Burst limits operate with a rolling interval. Therefore, the burst limits continuously evaluate the requests made within a dynamic time window (for example, the past minute). This allows for short bursts of activity, as long as the total number of requests in that rolling window does not exceed the burst limit. For example, If the burst limit is set to 10 requests per minute, the system will look back at the past 60 seconds each time a new request is made and count the total number of requests in that window.

If the total requests in that rolling minute exceed 10, the system blocks the request. Burst limits are intended to allow flexibility for short spikes in traffic, accommodating occasional bursts of activity while still ensuring that the overall rate is kept under control.

A rate limit that is applied to a very small time period. In API Connect, burst limits are defined for multiples of seconds or minutes. Burst limits are always hard. When a burst limit is reached, calls are not accepted until the time period has expired. Once that pause is over, calls continue to be accepted until a hard rate limit is

reached. Configuring a burst limit prevents usage spikes and ensures that the rate limit is evenly spread across its overall time period. For example, you might want to permit a total of 1000 calls per hour (rate limit) and a maximum spike of 50 calls per second (burst limit).

Note:
The system clock determines the start time for rate, and burst limits. The intervals are configured as follows:

- 1 second interval starts at each new second.
- 1 minute interval starts at the beginning of each minute.
- 1 hour interval starts at the beginning of each hour.
- 1 day interval starts at midnight UTC.
- 1 week interval starts on Thursday at 00:00:00 UTC.

Where can you apply rate limits?

You can configure rate limiting at several levels of an API and the Plan containing it. Each of the rate limits is tracked separately and when a hard limit is exceeded, calls at that point are no longer accepted until the start of the next time period.

The following list explains where you can configure rate limits:

Plan: all APIs
: You can define a general rate limit at the Plan level, and it affects all of the consumer orgs that use that Plan. When a rate limit is enforced for a Plan, the limit is checked before every call that involves any API contained in that Plan.
If you exceed the rate limit for a hard limit, the system rejects any API calls prescribed in the plan. For information on setting a rate limit for a Plan, see Editing a draft Product.

  Note: If the subscriber changes to a different Plan, only the Plan-level rates limit are reset. If there is a hard rate limit specified in the API's definition or assembly, that rate limit is still enforced under the new Plan.

Plan: API path and operation
: You can define a rate limit for a specific path and operation of an API within a Plan; for example, you might allow unlimited calls to a GET operation but enforce a limit on PUT operations for the same API. You can even define multiple rate limits on the same path and operation. If the rate limit is enforced, then the limit is checked before every call that involves the API's path and operation. For more information on configuring rate limits on API paths and operations within a plan, see the following topics:

  - Defining rate limits for an API operation
  - Describing Plans in your Product

API assembly
: When you apply a rate limit to an API assembly, the limit only affects calls at that point in the assembly. This allows you to define a more granular rate limit than if you set it on the API definition. If the Plan and the API definition allow a call to proceed but a hard limit that is set on the assembly is exceeded, the call is aborted at the point in the process flow where the rate limit is set. Any actions that appear in the assembly's process flow before the rate limit policy are executed. Only the actions that appear in the flow after the rate limit policy are aborted.

How can you test rate limits?

When you're ready to test rate limits on an API or Plan, execute a larger number of calls than specified by your rate limit, within a shorter period of time. If you set soft rate limits, check for warning messages that indicate when each limit is exceeded. If you set hard limits, you can tell it was enforced when the API call fails. You can also check the error messages to verify which calls exceeded the limits.

For more information on creating and configuring Catalogs, see Working with Catalogs.

API Connect components

The API Connect components provide a unified user experience across the API lifecycle. Changes in one stage of the API lifecycle are automatically reflected in the other components of API Connect.

- Cloud Manager
- The developer toolkit
- API Manager
- API Gateways
- Runtime
- Developer Portal
- API Analytics
- Typical tasks per interface component
- API Connect server requirements

Cloud Manager

The API Connect Cloud Manager component is used to manage the API Connect on-premises cloud. The Cloud Administrator uses this UI to:

- Define the cluster of *Management servers*, *Gateway servers*, and *containers* that are required in the cloud, and configure the topology. For information about Management servers and Gateway servers, see API Connect server requirements. For information about containers, see Runtime.
- Manage (modify, move, remove, restart, reboot) the servers in the cloud.
- Monitor the health of the cloud.
- Define and manage the provider organizations that develop APIs. (Assigned managers or owners of provider organizations can also complete this task.)
- Define additional cloud administrators, or set up users with roles that enable access to specific capabilities.
- Add user registries for authenticating users and securing APIs, and configure the secure transmission of data (for example, through websites).

For more information about the Cloud Manager, see Managing your cloud.

The developer toolkit

The developer toolkit provides the tools for modeling, developing, and testing APIs. The developer toolkit includes a command-line interface (CLI) and a corresponding graphical user interface, the API Designer.

API developers use the API management functions in the API Designer or the CLI to create draft API definitions for REST and SOAP APIs, or for OAuth provider endpoints that are used for OAuth 2.0 authentication. The API definitions can be configured to add the API to a Product, add a policy assembly flow (to manipulate requests/responses), and to define security options and other settings. APIs can then be tested locally prior to publishing, to ensure they are defined and implemented correctly.

Draft APIs (in their containing Products) that are created by using the API Designer, or CLI are published to Catalogs.

The developer toolkit is installed locally, for offline API and application development. For more information about the developer toolkit, see Developing your APIs and applications.

API Manager

The API Manager provides a user interface that facilitates promotion and tracking of APIs that are packaged within Products and Plans. API providers can move the Products through their lifecycle, and manage the availability and visibility of APIs and Plans.

Catalogs and Spaces are created in the API Manager to act as staging targets through which APIs, Plans, and Products are published to consumer organizations. API providers can stage their Products to Catalogs or Spaces, and then publish them to make the APIs in those Products visible on a *Developer Portal* for external discovery.

To control access to the available API management functions, users in the provider organization can be set up in the API Manager UI with assigned roles and permissions. API providers can also use the UI to manage the consumer organizations that sign up to access their APIs and Plans. Developer *communities* can additionally be created as a way of grouping together a collection of consumer organizations to whom a particular set of Products and Plans can be made available.

The API Manager UI also includes functions to manage the security of the API environment, and provides access to analytics information about API invocation metrics within customizable dashboard views.

For more information about the API Manager, see Managing your APIs.

API Gateways

Gateways enforce runtime policies to secure and control API traffic, provide the endpoints that expose APIs to the calling applications, and provide assembly functions that enable APIs to integrate with various endpoints. They also log and report all API interactions to the API Connect analytics engine, for real-time and historical analytics and reporting.

API Connect supports the following types of API gateways:

- DataPower Gateway (v5-compatible)
  The DataPower® Gateway is an enterprise API Gateway that is built for departments and cross-enterprise usage. In V10 API Connect, the DataPower Gateway is compatible with the V5 DataPower Gateway, so it is referred to in documentation as the "v5-compatible" (or "v5c") gateway. The v5-compatible gateway provides a comprehensive set of API policies for security, traffic management, mediation, acceleration, and non-HTTP protocol support.
- DataPower API Gateway
  The DataPower API Gateway was designed with the same security focus as the DataPower Gateway (v5-compatible). Where DataPower Gateway (v5 compatible) is built for flexibility, DataPower API Gateway is built specifically for the API use case, with resulting performance benefits.DataPower API Gateway is optimized for the cloud. Use this gateway if you are running applications in a public or private cloud and want to expose them as APIs.

Your API Connect deployment can include a virtual DataPower Gateway. Support for a physical DataPower Gateway is also available, subject to certain conditions.

For more information about the gateways, and a comparison of their features, see Gateway types.

Runtime

You can run applications and API implementations in API Connect in a containerized runtime.

Containerized runtime
: A containerized runtime environment provides a lightweight deployment location for APIs and applications. A container wraps an application in a complete file system that includes everything it needs to run, such as code, runtime, system tools, and system libraries. You can use Docker Swarm or Kubernetes containers to run your APIs and applications being managed by API Connect.

Developer Portal

The Developer Portal provides a customizable self-service web-based portal to application developers to explore, discover, and subscribe to APIs.

When API providers publish APIs in the API Manager, those APIs are exposed in the Developer Portal for discovery and usage by application developers in consumer organizations. Application developers can access the Developer Portal UI to register their applications, discover APIs, use the required APIs in their applications (with access approval where necessary), and subsequently deploy those applications.

The Developer Portal provides additional features, such as forums, blogs, comments, and ratings, for socialization and collaboration. API consumers can also view analytics information about the APIs that are used by an application, or used within a consumer organization. For more information, see Developer Portal: Socialize your APIs.

API Analytics

API Connect provides the capability to filter, sort, and aggregate your API event data. This data is then presented within correlated charts, tables, and maps, to help you manage service levels, set rate limits, establish controls, set up security policies, manage communities, and analyze trends. API analytics is built on the OpenSearch open source real-time distributed search and analytics engine. For more information, see Analytics: understand your API usage.

API Connect server requirements

From an on-premises cloud, you can create, promote, use, and track APIs. An on-premises cloud is composed of various appliances, where each appliance is a server of a specific type. The collection of servers defines your cloud and determines how to distribute the work of managing, analyzing, routing, and storing data.

Your on-premises cloud can be a combination of new and existing physical appliances and virtual appliances, or can be entirely composed of virtual appliances. The type and quantity of servers in an API Connect environment are determined by the individual needs of each enterprise, but the minimum requirement is one Management server, one Analytics server, one Gateway server, and one server to host the Developer Portal.

The API Connect on-premises cloud includes the following server types:

- Management server. Stores all of the cloud configuration, and controls communication between the other servers within API Connect. Manages the operations of the various servers in the API Connect cloud and provides the tools to interface with the various servers. The Cloud Manager and API Manager user interfaces run on the Management server.
- Analytics server. Provides analytic functions that collect and store information about APIs and API users.
- Gateway server. Processes and manages security protocols and stores relevant user and appliance authentication data. The Gateway server also provides assembly functions that enable APIs to integrate with various endpoints, such as databases or HTTP-based endpoints.
- **Developer Portal server**. Provides a customizable social developer portal with a full-featured content management system, and includes clustering capability. Enables API providers to build portals for their application developers, and provides the interface for application developers to discover APIs and subscribe to usage Plans contained in the published Products for use in their applications.

Note: All Management appliances in an API Connect cloud must run at the same firmware level as each other. Gateway appliances can run on different firmware levels to each other, but it is recommended that all of the Gateway appliances run on the same level as each other.

Typical tasks per interface component

API Connect offers both command line and graphical user interfaces. Provider and consumer organizations use different interfaces for completing typical tasks. Refer to the following table to locate the interface that corresponds to a specific task.

Table 1. API Connect Tasks per interface component

Organization Type	Interface Component	Tasks
API Provider	Command Line Interface (CLI)	Create APIs, Plans, and Products
	API Designer UI	Create APIs, Plans, and Products
	API Manager UI	Create Catalogs and Spaces; Create Consumer Organizations
	Cloud Manager UI	Create Provider Organizations
API Consumer (application developer)	Developer Portal	Access APIs to create and run applications; Create Consumer Organizations

If self-service onboarding is enabled for a Catalog, a consumer organization is automatically created when an application developer signs up or is invited by the API provider to a Developer Portal, and the application developer then becomes the owner of that consumer organization.

- **Gateway types**
  IBM API Connect provides the different types of gateways for use with your deployment.

Related concepts

- Packaging strategy and terminology in API Connect

Gateway types

IBM® API Connect provides the different types of gateways for use with your deployment.

DataPower API Gateway

The DataPower® API Gateway has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible). Where DataPower Gateway (v5 compatible) was built for flexibility, DataPower API Gateway is built specifically for the API use case, with resulting performance benefits.

DataPower API Gateway was built and optimized for the cloud. Use this gateway if you are running applications in a public or private cloud and want to expose them as APIs.

DataPower Gateway (v5 compatible)

DataPower Gateway (v5 compatible) provides compatibility with the IBM DataPower Gateway that was provided with IBM API Connect Version 5 and earlier releases.

Consider using DataPower Gateway (v5 compatible) if you are an existing DataPower user and want to utilize your DataPower resources and knowledge.

DataPower gateway comparison

The following table compares support for features between the gateway types. For v5-compatible features and policies that are not supported in DataPower API Gateway, you can use the API Connect Migration Utility (AMU) to migrate them to an API Gateway-compatible format. For more information, see Migrating a Version 5 deployment .

Table 1. Comparison of the DataPower Gateway (v5 compatible) and DataPower API Gateway

Feature	DataPower Gateway (v5 compatible)	DataPower API Gateway
Native policies	No	Yes
OAuth provider	Full OAuth 2.0 Support	Full OAuth 2.0 Support

Feature	DataPower Gateway (v5 compatible)	DataPower API Gateway
OAuth policy	No	Yes
OpenID Connect	Supported through a template	Supported natively
Invoke policy	Yes	Yes
Custom policies	Yes	Yes
Conditional policies	if, operation-switch, switch	switch
Activity logging	Implicitly executed at the end of API assembly	Configured in the API design, outside of the API assembly.
GatewayScript	Yes	Yes
Parse policy (threat detection)	No	Yes
Gateway extensions	Yes	Yes
Support for mutual TLS (mTLS)	Yes	Yes

Attention: Version 5-compatible gateways and DataPower API Gateways have different mechanisms for interacting with the API context for GatewayScript and XSLT policies, or if you are authoring user-defined policies. Ensure that you are using the correct mechanisms for your gateway type:

- For v5-compatible gateways and v5 compatibility for APIs created for the API Gateway, see GatewayScript code examples and XSLT policy examples.
- For DataPower API Gateway, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Event Gateway

Event Endpoint Management provides the capability to describe and catalog your Kafka topics as event sources, and to grant access to application developers within the organization. Application developers can discover event endpoints and configure their applications to access them through the event gateway. With Event Endpoint Management, developers can control access to the event endpoints, and also control what data can be produced to them or consumed from them.

For more information on Event Endpoint Management, see the Event Endpoint Management introduction in the IBM Event Automation documentation.

API Connect support

If you experience a problem with IBM® API Connect that you cannot resolve, you can check the IBM Support website for the most recent technical bulletins and fixes. Otherwise, you can contact IBM Support.

For the most recent API Connect technical information, see the IBM Support Community.

If you cannot find a resolution, before you contact IBM Support, you must gather information about the problem. For details of the information you must gather before contacting IBM Support, see MustGather - Collecting data: API Connect problem determination.

Providing IBM Support with a good description of the problem together with the details of your API Connect configuration, helps to expedite the problem resolution.

API Connect glossary

The IBM® API Connect and Cloud Manager glossary of terms and definitions.

API Administrator (role)
: Manages the API product lifecycle for the Provider Organizations for which they are a member.

API Event
: An event captured for use by API Connect Analytics or third-party analytics, such as response time, HTTP response code, payload of the request and response body, and so on. An API event is logged each time an API operation is invoked via the Gateway server.

API Gateway
: Service that acts as a single entry point or “front door” for provider APIs and back-end services. An API Gateway accepts and processes concurrent API calls, and performs traffic management, authorization and access control, monitoring, and API version management. See also IBM DataPower Gateway.

API Manager
: Graphical tool in API Connect that enables you to manage Catalogs, Spaces, and APIs, users and roles in the Provider organization, consumer organizations and communities, publish Products to the Developer Portal, and analyze API usage.

API Designer
: Graphical tool that runs locally on a laptop or desktop system that enables you to create and modify APIs, and publish them to IBM Cloud or container runtimes.

API operation
: REST API call consisting of an HTTP verb and a URL path (endpoint). For example, `GET http://myserver.com/api/users` that returns a list of users.

Application
: Software that consumes (calls) an API. One or more Applications are registered by a consumer organization to subscribe to APIs. The application is allocated client ID and client secret credentials that it supplies when invoking API calls.

assembly
: Makes side calls to external services and then transforms and aggregates the response before a response is relayed to the calling application.

Availability zones
: In API Connect these are logical groupings of API Connect services that will typically reflect the deployment environment. For example, you could have availability zones named `internal` and `external` to reflect the APIs published in each. Or they could be defined by the geographic location the services are running in.

Catalog
: A staging target that behaves as a logical partition of the gateway and the Developer Portal. The URLs for API calls and for the Developer Portal are specific to a particular Catalog.

client ID
: A piece of information that identifies an individual application. An application can invoke an API only if it passes an application key that is recognized by the IBM API Connect system and is granted access to the API. The application key is passed by the client by using an HTTP query parameter.

client secret
: A piece of information used together with the application key to verify the identity of an application. An API can be configured to require that client applications supply their client secret with their client ID. The client secret functions effectively as a password known only to the application. The client secret is passed by the

client by using an HTTP query parameter.

Cloud Manager (tool)
: Graphical tool in API Connect on-premises installation that enables you to define servers, administer and scale system resources, monitor runtime health and create Provider organizations. The Cloud Administrator is the primary user of the Cloud Manager.

Cloud Administrator (role)
: Manages the configuration of resources, regions, and availability zones for the Admin Organization of an on-premises installation.

cluster
: A collection of one or more servers that provide a specific function.

Cold standby
: A deployment configuration in which failover servers are in a stopped state until a failover is required, resulting in a longer time window to restore the normal operation of the solution.

community
: A collection of consumer organizations. It is used as a grouping construct when publishing APIs. Communities are used to restrict the visibility and accessibility of APIs. An API can be published to selected communities, which means that only application developers within those organizations can see the API.

Community Manager (role)
: Manages application developer communities for the Provider Organizations for which they are a member.

Consumer organization
: Within a catalog, representation of a business entity that wishes to consume APIs exposed by the Catalog. For example, a third-party application development company would register themselves as a consumer organization (via the Developer Portal). Each developer in their company can then be registered as a user inside that consumer organization.

IBM DataPower® Gateway
: API Gateway service component of API Connect that helps provide security, control, integration and optimized access to APIs. Due to its security and hardening, it is well-suited for a deployment in the demilitarized zone (DMZ) for externally-facing production scenarios. Available in physical, virtual, cloud, Linux and Docker form factors. There are two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway; for details, see Gateway types.

Developer (role)
: Creates and configures APIs, Products, and policies for the Provider Organizations for which they are a member. An API Developer can be a member of one or more Provider Organizations. The API Developer focuses on the technical implementation of APIs more than they do on the business relationship with application developers.

Development Catalog
: Catalog used for testing APIs that are under development and in which approvals are bypassed for publishing and lifecycle actions. Pending approvals are canceled when a non-Development Catalog is converted to a Development Catalog.

Developer Portal
: Component of API Connect that provides a customizable graphical web portal for developers to discover APIs, register applications that consume APIs, subscribe to usage plans, and test and use APIs.

Developer Toolkit
: Locally-installed package that includes API Designer and the **`apic`** command-line tool that enables you to create, edit, manage, and publish APIs and apps.

Gateway
: See API Gateway.

Gateway service
: API Connect service that provides API gateway functionality, such as microgateway or IBM DataPower.

Hot standby
: A deployment configuration in which a set of servers are actively running ready to instantaneously take over in the event of a failure, but not actively serving traffic until that failover.

Identity provider
: Provides identifiers for users looking to interact with a system, assert to such a system that such an identifier presented by a user is known to the provider, and possibly provide other information about the user that is known to the provider. API Connect supports LDAP, AuthURL, and Local User Registries.

Integrations
: Third-party tools to build on and improve your API Connect workflow; for example, Slack, Auth0, etc.

Integration profile
: Standard API that you can use to integrate with management services for things like identity, notifications, API analytics, and so on.

Keystore
: A repository of security certificates, either authorization certificates or public key certificates, and corresponding private keys, used in SSL encryption. The Keystore file has a **`.jks`** extension.

Management server
: Stores all of the cloud configuration, and controls communication between the other servers within API Connect.

Management service
: Consists of one or more Management servers.

Member (role)
: The default role for all users in both the Admin and Provider Organization. All users are assigned the Member role in addition to other roles they may require.

microservice
: Modular, independently-deployable application service that communicates with other microservices through a REST API. Microservices are typically organized around capabilities, for example, recommendation, inventory, shipping, or billing.

Mutual authentication
: Process in which both entities on a network authenticate each other. In a network environment, the client authenticates the server and vice-versa. It is optional for TLS. Also called two-way authentication.

Notification settings
: How you configure notifications for API Connect users (API providers and consumers).

Notification services
: Integrations that provide notification capabilities, such as email.

Notification templates
: The configuration of the message format and wording for a notification service.

OAuth provider
: The OAuth provider supplies the OAuth authentication for logins. API Connect supports both Native and Third Party OAuth providers. Some common third-party OAuth providers are Google and Facebook.

OpenAPI Components
: Part of API specification that contains a set of reusable objects for aspects of an API specification, such as schemas, responses, reqeustBodies, and headers. For more information, see [OpenAPI v3 specification](https://github.com/OAI/OpenAPI-Specification/blob/OpenAPI.next/versions/3.0.md#components-object).

organization
: The entity that owns APIs or applications that use APIs. A provider organization owns APIs and associated Plans, and can additionally own applications. A consumer organization owns only applications. An organization has at least one owner. An organization can be a project team, department, or division.

Organization Manager (role)
: The Organization Manager manages Provider Organizations for the Admin Organization.

Path
: Defines the route through which users access REST APIs. A path consists of one or more HTTP operations such as GET or POST.

Plan
: The packaging construct by which APIs are made available to developers. A Plan makes a collection of operations from one or more APIs available, and is published to communities of application developers. Application developers gain access to APIs by registering applications to access Plans. A Plan carries with it a collection of policy settings. In the simplest form, a Plan defines a single quota policy that applies to all the API operations that are accessed through the Plan. In more advanced cases, additional policies can be associated with a Plan.

policy
: A configuration that controls a specific aspect of processing in the Gateway server during the handling of an API invocation at run time. Policies are the building blocks of assembly flows. Policies provide the means to configure capability, such as security, logging, routing of requests to target services, and transformation of data from one format to another. Policies can be configured in the context of an API or in the context of a Plan.

Product
: Provide a method by which you can group APIs into a package that is intended for a particular use. Additionally, they contain Plans, which can be used to differentiate between different offerings. You can create Plans only within Products, and these Products are then published in a Catalog.

Provider Organization Owner
: Owns and administers API provider organizations, manages application developer communities, authors APIs and defines products, manages the API product lifecycle. Owners are invited by the Cloud Administrator to join API Connect as an owner of a provider organization.

proxy
: Application programming interface that forwards requests to a user-defined back-end resource and relays responses back to the calling application.

Region
: A physical location (site or data center) hosting infrastructure isolated from other locations, with independent power and networking connectivity. A region may or may not have further sub-isolation characteristics such as semi-independent pods or availability zones.

Resources (User registries, TLS Profiles, Notifications)
: Resources supply necessary functions for the API Connect cloud, such as user authentication, SSL security, and sending system-generated emails.

role
: Defines permissions that can enable functionality for users. Each role has a different set of permissions.

security definition
: Specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

server
: A single appliance, such as an IBM WebSphere IBM DataPower appliance.

service
: A user-configurable element implemented through one or more server processes in the API Connect runtime, such as microgateway, Analytics, IBM DataPower, and Developer Portal.

SNMP
: Simple Network Management Protocol (SNMP) is a popular protocol for network management. It is used for collecting information from, and configuring, network devices, such as servers, printers, hubs, switches, and routers on an Internet Protocol (IP) network. The SNMP hosts are configured in the API Connect Cloud Manager.

Space
: A subdivision of a Catalog. Each Space is used by a different API provider development team and has its own set of management capabilities relating specifically to the APIs that the associated team publishes to that Space, enabling each team to manage their APIs independently.

SSL (TLS) Profile
: An SSL/TLS profile is used to secure the transmission of data through web sites. SSL certificates guarantee that information you submit to web sites will not be stolen or tampered with.

subscription
: The means by which an application developer gains access to the resources provided by an API. An application developer uses the Developer Portal to subscribe to the plan in which the API is published.

TLS
: Transport Layer Security - a cryptographic protocol that provides secure communication over a network to prevent eavesdropping and tampering. It is a successor to SSL and runs over TCP.

TLS Profiles
: The Cloud Manager and API Manager use TLS profiles to secure transmission of data through web sites. TLS certificates guarantee that information you submit to web sites will not be stolen or tampered with. A TLS Profile consists of Server name, Protocol used (SSL or TLS), and whether Mutual Authentication is required.

Toolkit
: See Developer Toolkit.

Topology administrator (role)
: Configures gateway services for the Admin Organization.

Truststore
: Stores certificates from trusted Certificate authorities(CA) which are used to verify certificate presented by Server in SSL/TSL Connection. While a keystore stores a server's credentials, the truststore stores certificates from a third-party CA.

User registry
: A database or other collection containing credentials for users such as provider organization members, consumer organization members, and API Connect administrators. The users are authenticated by an identity provider such as LDAP. User registries authenticate users at login time when accessing the Cloud Manager or API Manager applications. User registries are also be used to protect APIs so that user credentials must be supplied when an API is called.

vendor extension
: An extension to OpenAPI (Swagger) specification required by a particular use case.

Visibility
: Setting visibility determines whether a Provider Organization has access to an Availability Zone, or other service.

Accessibility features for IBM API Connect

Accessibility features help users who have a physical disability, such as restricted mobility or limited vision, to use information technology products successfully.

Accessibility features

The following list includes the major accessibility features in IBM® API Connect Enterprise. You can use screen-reader software to hear what is displayed on the screen.

- Supports keyboard-only operation.
- Supports interfaces commonly used by screen readers.

Tip: This product documentation, and its related publications, are accessibility-enabled for the IBM Home Page Reader. You can operate all features by using the keyboard instead of the mouse.
If you are reading a PDF file with a screen reader, the default reading option typically returns the best results. In some cases, how the PDF file is generated might require you to select one of the other reading options. For example, Use reading order in raw print stream.

Keyboard navigation

This product uses standard Linux® and Microsoft Windows navigation keys.

For more information about the commitments that IBM makes towards accessibility, see the IBM Accessibility Center.

Legal information

Notices, and terms and conditions for information centers.

- **Tracking API volume for auditing and compliance**
  For client security reasons, IBM entrusts its clients with monitoring their own API volume and ensuring that it is within the limits of the contract.
- **Notices**
  This information was developed for products and services offered in the U.S.A.
- **Terms and conditions for information centers**
  Permissions for the use of these publications are granted subject to the following terms and conditions.

Tracking API volume for auditing and compliance

For client security reasons, IBM entrusts its clients with monitoring their own API volume and ensuring that it is within the limits of the contract.

If you purchased IBM API Connect with a license metric of "API Calls", the count of total API Calls must be collected and archived by the client for audit and compliance. This includes, but is not limited to, licensed programs: "IBM API Connect Hybrid Entitlement" and "IBM Cloud Pak for Integration - API Calls".

Usage archiving

You **are required to regularly** record the number of your API calls from the Analytics **system** to maintain a record of **monthly** usage. To ensure the most accurate results, capture the counts of API Calls daily. For information about viewing API call counts and creating a query that counts API calls for **all** response status codes and for a specified time range, see Counting total API calls for your analytics service.

Overage charging

If you exceed your allotted usage, it is your responsibility to report this to IBM in the form of a CSV file so that the correct overage charge can be applied. IBM has the right to audit customer usage data at any time. If unreported overages are found, there are severe penalties.

Overage is based on the measurement period. For example, overage for a contract might be measured by the year. If your API volume exceeds the entitlement after 6 months, you must either pay overages for the remaining period or purchase additional volume.

Notices

This information was developed for products and services offered in the U.S.A.

IBM® may not offer the products, services, or features discussed in this document in other countries. Consult your local IBM representative for information on the products and services currently available in your area. Any reference to an IBM product, program, or service is not intended to state or imply that only that IBM product, program, or service may be used. Any functionally equivalent product, program, or service that does not infringe any IBM intellectual property right may be used instead. However, it is the user's responsibility to evaluate and verify the operation of any non-IBM product, program, or service.

IBM may have patents or pending patent applications covering subject matter described in this document. The furnishing of this document does not grant you any license to these patents. You can send license inquiries, in writing, to:

IBM Director of Licensing
IBM Corporation
North Castle Drive
Armonk, NY 10504-1785
U.S.A.

For license inquiries regarding double-byte character set (DBCS) information, contact the IBM Intellectual Property Department in your country or send inquiries, in writing, to:

Intellectual Property Licensing
Legal and Intellectual Property Law
IBM Japan Ltd.

1623-14,
Shimotsuruma,
Yamato-shi
Kanagawa
242-8502 Japan

The following paragraph does not apply to the United Kingdom or any other country where such provisions are inconsistent with local law: INTERNATIONAL BUSINESS MACHINES CORPORATION PROVIDES THIS PUBLICATION "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESS OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF NON-INFRINGEMENT, MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE. Some states do not allow disclaimer of express or implied warranties in certain transactions, therefore, this statement may not apply to you.

This information could include technical inaccuracies or typographical errors. Changes are periodically made to the information herein; these changes will be incorporated in new editions of the publication. IBM may make improvements and/or changes in the product(s) and/or the program(s) described in this publication at any time without notice.

Any references in this information to non-IBM Web sites are provided for convenience only and do not in any manner serve as an endorsement of those Web sites. The materials at those Web sites are not part of the materials for this IBM product and use of those Web sites is at your own risk.

IBM may use or distribute any of the information you supply in any way it believes appropriate without incurring any obligation to you.

Licensees of this program who wish to have information about it for the purpose of enabling: (i) the exchange of information between independently created programs and other programs (including this one) and (ii) the mutual use of the information which has been exchanged, should contact:

IBM United Kingdom Laboratories,
Mail Point 151,
Hursley Park,
Winchester,
Hampshire,
England
SO21 2JN

Such information may be available, subject to appropriate terms and conditions, including in some cases, payment of a fee.

The licensed program described in this information and all licensed material available for it are provided by IBM under terms of the IBM Customer Agreement, IBM International Program License Agreement, or any equivalent agreement between us.

Any performance data contained herein was determined in a controlled environment. Therefore, the results obtained in other operating environments may vary significantly. Some measurements may have been made on development-level systems and there is no guarantee that these measurements will be the same on generally available systems. Furthermore, some measurements may have been estimated through extrapolation. Actual results may vary. Users of this document should verify the applicable data for their specific environment.

Information concerning non-IBM products was obtained from the suppliers of those products, their published announcements or other publicly available sources. IBM has not tested those products and cannot confirm the accuracy of performance, compatibility or any other claims related to non-IBM products. Questions on the capabilities of non-IBM products should be addressed to the suppliers of those products.

All statements regarding IBM's future direction or intent are subject to change or withdrawal without notice, and represent goals and objectives only.

This information contains examples of data and reports used in daily business operations. To illustrate them as completely as possible, the examples include the names of individuals, companies, brands, and products. All of these names are fictitious and any similarity to the names and addresses used by an actual business enterprise is entirely coincidental.

COPYRIGHT LICENSE:

This information contains sample application programs in source language, which illustrate programming techniques on various operating platforms. You may copy, modify, and distribute these sample programs in any form without payment to IBM, for the purposes of developing, using, marketing or distributing application programs conforming to the application programming interface for the operating platform for which the sample programs are written. These examples have not been thoroughly tested under all conditions. IBM, therefore, cannot guarantee or imply reliability, serviceability, or function of these programs.

Each copy or any portion of these sample programs or any derivative work, must include a copyright notice as follows:

© (your company name) (year). Portions of this code are derived from IBM Corp. Sample Programs. © Copyright IBM Corp. _enter the year or years_. All rights reserved.

Trademarks

IBM, the IBM logo, and ibm.com® are trademarks or registered trademarks of International Business Machines Corp., registered in many jurisdictions worldwide. Other product and service names might be trademarks of IBM or other companies. A current list of IBM trademarks is available on the Copyright and trademark information page at https://www.ibm.com/legal/copytrade.shtml.

Java™ and all Java-based trademarks and logos are trademarks or registered trademarks of Oracle and/or its affiliates.

Linux® is a registered trademark of Linus Torvalds in the United States, other countries, or both.

Kubernetes is a trademark of the Linux Foundation in the United States, other countries, or both.

Microsoft and Windows are trademarks of Microsoft Corporation in the United States, other countries, or both.

OpenShift® is a trademark of Red Hat®, Inc. in the United States, other countries, or both.

VMware is a registered trademark or trademark of VMware, Inc. in the United States and other jurisdictions.

Other company, product, and service names might be trademarks of IBM or other companies.

Privacy Policy Considerations

IBM Software products, including software as a service solutions, (*Software Offerings*) may use cookies or other technologies to collect product usage information, to help improve the user experience, to tailor interactions with the user or for other purposes. In many cases no personally identifiable information is collected by the Software Offerings. Some of our Software Offerings can help enable you to collect personally identifiable information. If this Software Offering uses cookies to collect personally identifiable information, specific information about this offering's use of cookies is set forth in the following paragraphs.

Depending upon the configurations deployed, this Software Offering may use session and persistent cookies that collect each user's session ID for purposes of session management, or functional purposes. These cookies can be disabled, but disabling them will also eliminate the functionality they enable.

If the configurations deployed for this Software Offering provide you as customer the ability to collect personally identifiable information from users via cookies and other technologies, you should seek your own legal advice about any laws applicable to such data collection, including any requirements for notice and consent.

For more information about the use of various technologies, including cookies, for these purposes, See IBM's Privacy Policy at https://www.ibm.com/privacy and IBM's Online Privacy Statement at https://www.ibm.com/privacy/details the section entitled *Cookies, Web Beacons and Other Technologies* and the *IBM Software Products and Software-as-a-Service Privacy Statement* at https://www.ibm.com/software/info/product-privacy.

Terms and conditions for information centers

Permissions for the use of these publications are granted subject to the following terms and conditions.

Applicability

These terms and conditions are in addition to any terms of use for the IBM® website.

Personal use

You may reproduce these publications for your personal, noncommercial use provided that all proprietary notices are preserved. You may not distribute, display or make derivative work of these publications, or any portion thereof, without the express consent of IBM.

Commercial use

You may reproduce, distribute and display these publications solely within your enterprise provided that all proprietary notices are preserved. You may not make derivative works of these publications, or reproduce, distribute or display these publications or any portion thereof outside your enterprise, without the express consent of IBM.

Rights

Except as expressly granted in this permission, no other permissions, licenses or rights are granted, either express or implied, to the publications or any information, data, software or other intellectual property contained therein.

IBM reserves the right to withdraw the permissions granted herein whenever, in its discretion, the use of the publications is detrimental to its interest or, as determined by IBM, the aforementioned instructions are not being properly followed.

You may not download, export or re-export this information except in full compliance with all applicable laws and regulations, including all United States export laws and regulations.

IBM MAKES NO GUARANTEE ABOUT THE CONTENT OF THESE PUBLICATIONS. THE PUBLICATIONS ARE PROVIDED "AS-IS" AND WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING BUT NOT LIMITED TO IMPLIED WARRANTIES OF MERCHANTABILITY, NON-INFRINGEMENT, AND FITNESS FOR A PARTICULAR PURPOSE.

IBM API Connect Considerations for GDPR Readiness

Information about features of IBM® API Connect that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness.

For PID(s): 5725-Z22 5725-Z63

Notice:

This document is intended to help you in your preparations for GDPR readiness. It provides information about features of API Connect that you can configure, and aspects of the product's use, that you should consider to help your organization with GDPR readiness. This information is not an exhaustive list, due to the many ways that clients can choose and configure features, and the large variety of ways that the product can be used in itself and with third-party applications and systems.

Clients are responsible for ensuring their own compliance with various laws and regulations, including the European Union General Data Protection Regulation. Clients are solely responsible for obtaining advice of competent legal counsel as to the identification and interpretation of any relevant laws and regulations that may affect the clients' business and any actions the clients may need to take to comply with such laws and regulations.

The products, services, and other capabilities described herein are not suitable for all client situations and may have restricted availability. IBM does not provide legal, accounting, or auditing advice or represent or warrant that its services or products will ensure that clients are in compliance with any law or regulation.

4. Data Collection
5. Data Storage
6. Data Access
7. Data Processing
8. Data Deletion
9. Data Monitoring
10. Capability for Restricting Use of Personal Data

GDPR

General Data Protection Regulation (GDPR) has been adopted by the European Union ("EU") and applies from May 25, 2018.

Why is GDPR important?

GDPR establishes a stronger data protection regulatory framework for processing of personal data of individuals. GDPR brings:

- New and enhanced rights for individuals
- Widened definition of personal data
- New obligations for processors
- Potential for significant financial penalties for non-compliance
- Compulsory data breach notification

Read more about GDPR

- Complete guide to GDPR compliance
- IBM GDPR website

Product Configuration - considerations for GDPR Readiness

The following sections provide considerations for configuring API Connect to help your organization with GDPR readiness.

Configuration to support data handling requirements

The GDPR legislation requires that personal data is strictly controlled and that the integrity of the data is maintained. This requires the data to be secured against loss through system failure and also through unauthorized access or via theft of computer equipment or storage media.
IBM API Connect stores identity data in a local database. This encompasses both clients' employee identity data and end users' identity data. Direct access to this database is not available. Identity information collected is protected in transit; refer to Creating a TLS Server Profile for details on configuring TLS profiles.

API Connect supports a variety of user registry types for authenticating users. Refer to Authenticating by using your enterprise user directory for details. When using a local user registry, passwords are stored in encrypted form in the local API Connect database. If you want alternative password management, leverage a non-user registry option to manage passwords.

Administrators, that you define, can view identity information. Administrators can take backups that include identity information. It is your responsibility to protect these backups.

A core component for an API Connect deployment is the gateway. Refer to the section on API Gateways (in the *API Connect components* topic) for details about gateways. DataPower® Gateways are commonly leveraged; refer to the DataPower Gateway documentation for details. Refer to the DataPower Gateway deployment guidelines document for considerations for configuring DataPower Gateways to help your organization with GDPR readiness.

Configuration to support Data Privacy

For Developer Portal, you can customize the privacy policy statement. Refer to Customizing the privacy policy statement for details.

Configuration to support Data Security

To learn about securing your solution, use this API Connect product documentation and search for "security".

Data Life Cycle

GDPR requires that personal data is:

- Processed lawfully, fairly and in a transparent manner in relation to individuals.
- Collected for specified, explicit and legitimate purposes.
- Adequate, relevant and limited to what is necessary.
- Accurate and, where necessary, kept up to date. Every reasonable step must be taken to ensure that inaccurate personal data are erased or rectified without delay.
- Kept in a form which permits identification of the data subject for no longer than necessary.

API Connect manages the life cycle of user-related data in the following ways:

User account information

API Connect collects and stores identity information, including first and last name, and email address, for the purposes of user registration. Cloud Manager and API Manager accounts are for your employees (or designated actors). Developer Portal accounts are for your consumers of your APIs. Identity information can be collected directly from users or can be copied from LDAP registries. In situations where non-local user registries are used, only the email address is copied from the LDAP registry. Developer Portal user accounts can be deleted; refer to Deleting your Developer account for details. Cloud Manager and API Manager user accounts' identity information can be anonymized by users.
Users of the API Manager UI can publish Products and APIs to the Developer Portal for Application Developers to access and use. Refer to Developer Portal: socialize your APIs to learn about Developer Portal. Developer Portal accounts are for consumers of your APIs. You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal; refer to Customizing the terms of use statement for details.

API analytics

API Connect optionally logs information related to API invocations. This capability in API Connect is known as API Analytics. Refer to Analytics: understand your API usage for details.

The API Analytics log information can optionally include unknown / unclassified information such as query headers and request and response information related to API calls -- you control defining the APIs and data associated with API invocations.

The retention period for storing Analytics data in API Connect is configurable; refer to Retention and rollover for details. Backup capability for this information is not available.

To disable API Analytics, disassociate it from the gateway that collects event data. For information, refer to Associating an analytics service with a gateway service.

System logs

Event-logging preferences can be configured at the API level, refer to Activity Log for details.

API Connect logs collect technical information related to service use including tracing of service execution and sequences of operation use. Other technical data related to service use includes data values that define the mechanisms used to connect to the service, for example, IP address. This data is collected for debugging and service improvement. Service diagnostics are collected during unexpected or error situations to allow the offering team to correct the situation and hopefully prevent it from occurring in the future. There is no direct access available to these logs.You can configure log settings and download the logs as explained in Logging.

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization; for example, publishing a product or creating an organization triggers this event. Refer to Configuring audit logging to monitor user operations for details.

Data Collection

Developer Portal accounts are for consumers of your APIs. You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal; refer to Customizing the terms of use statement for details. You can also customize the privacy policy statement for Developer Portal; refer to Customizing the privacy policy statement for details.

Types of Data Collected

API Connect collects and stores identity information (including first name, last name, and email address) for the purposes of user registration. Cloud Manager and API Manager accounts are for your employees (or designated actors). Developer Portal accounts are for your consumers of your APIs. Identity information can be collected directly from users or can be copied from LDAP registries. In situations where non-local user registries are used, only the email address is copied from LDAP registry. Developer Portal user accounts can be deleted; refer to Deleting your Developer account for details. Cloud Manager and API Manager user accounts' identity information can be anonymized by users.

Data Storage

Identity data is stored in API Connect local data store. There is no direct access available to this data store.

API Analytics leverages the OpenSearch real-time distributed search and analytics engine for storage of logged data. There is no direct access available to this data store.

Identity data is included in backups; refer to Backing up and restoring for details on taking backups. It is your responsibility to protect and discard backups.

Data Access

Identity information can be viewed by administrators that you define.

Analytics information can be accessed through a variety of means. Refer to Access your analytics data for details.

Analytics information can be offloaded to third-party systems. Refer to Offloading to third-party systems for details. It is your responsibility to protect off-loaded data.

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization; for example, publishing a product or creating an organization triggers this event. Refer to Configuring audit logging to monitor user operations for details.

API Connect logs collect technical information related to service use including tracing of service execution and sequences of operation use. Other technical data related to service use includes data values that define the mechanisms used to connect to the service, for example, IP address. This data is collected for debugging and service improvement. Service diagnostics are collected during unexpected or error situations to allow the offering team to correct the situation and hopefully prevent it from occurring in the future. There is no direct access available to these logs.You can configure log settings and download the logs as explained in Logging.

Data Processing

Data collected by API Connect or to gateways via API invocations is protected by TLS in transit. Refer to Creating a TLS Server Profile for details.

Data is stored in API Connect local database on the API Connect appliances. There is no direct access available to this data.

Cloud Manager and API Manager administrators (defined by you) have read access to identity data.

Data Deletion

Right to Erasure

Article 17 of the GDPR states that data subjects have the right to have their personal data removed from the systems of controllers and processors -- without undue delay -- under a set of circumstances.

Data Deletion characteristics

Users can delete their own Developer Portal user accounts -- refer to Deleting your Developer account for details. Cloud Manager and API Manager user account identity data can be anonymized by the users to remove association with the account data.
Technical information related to service use collected in logs is rolled over based on size and time criteria.

To disable API Analytics, disassociate it from the gateway that collects event data. For information, refer to Associating an analytics service with a gateway service.

The retention period for storing Analytics data in API Connect is configurable; refer to Retention and rollover for details. Backup capability for this information is not available.

Analytics information can be offloaded to third-party systems. Refer to Offloading to third-party systems for details. You are responsible for the security of off-loaded data.

Identity information for accounts is included in system backups. You manage the deletion of system backups.

Data Monitoring

Customers should regularly test, assess, and evaluate the effectiveness of their technical and organizational measures to comply with GDPR. These measures should include ongoing privacy assessments, threat modeling, centralized security logging, and monitoring

API Connect can generate audit events. An audit event is logged from each management node when there are changes to the API lifecycle or to the organization; for example, publishing a product or creating an organization triggers this event. Refer to Configuring audit logging to monitor user operations for details.

Capability for Restricting Use of Personal Data

Users of the API Manager UI can publish Products and APIs to the Developer Portal for Application Developers to access and use. Refer to Developer Portal: socialize your APIs to learn about Developer Portal. Developer Portal accounts are for consumers of your APIs.

You can define and customize a terms and conditions statement that your users must accept before they can register to use your Developer Portal; refer to Customizing the terms of use statement for details. You can also customize the privacy policy statement for Developer Portal; refer to Customizing the privacy policy statement for details.

Developer Portal users can modify their own account information, and can delete their account.

Essential reading

These articles by IBM® API Connect product specialists provide a wealth of supporting information on APIs and the API economy.

Why Become a Digital Business?
: Executing a Digital Transformation to become a Digital Business is among the hottest initiatives now – crossing both business and IT. But, is this just the latest buzzword or is there something to this that is different? Do you know **why** you should become a “Digital Business”?

Creating A Digital Ecosystem – Past, Present, and Future
: The ability to create a digital ecosystem is critical to digital transformation success. Your success is your network reach.

Agile integration
: Your business needs a modern, agile approach to integration. It should empower extended teams to create integrations, leverages a complete set of integration styles and capabilities, and increases overall productivity.

What is an API? and What is the API Economy?
: Businesses start to consider APIs and the API Economy at various times. Many are long down their API journeys, while others are still considering whether to start. This article looks at some of the basics that companies considering APIs might want to know.

What is API Management?
: APIs are not new. Software and hardware have had APIs (Application Programming Interfaces) for decades. However, *having* an API and *managing* an API are not the same thing.

Providing APIs or Managing APIs – There is a Big Difference
: A discussion of the potential for confusion between APIs that are provided and APIs that are managed.

Recommendations for an API Economy Center of Excellence
: What roles are required to drive a successful API initiative, how should this fit in the current organization, and how do these roles relate to existing roles in the company?

Focus on the API Developer
: A productive developer is a happy developer. One of the most frequently discussed topics in the API economy is focusing on the needs of the Application developer – the consumer target for your APIs.

Agile API development
: Agile API Development Customer expectations and behavior are continuously changing. To deliver exceptional customer experience, a business must be nimble to adapt to these changing needs.

API Products – Who, What, Where, When, Why and How”
: An API Product is an API offering made available for consumer use that is offered to a target market to satisfy a customer’s needs.

Changing Culture – How Committed Are You?
: How do we change the culture in our organization to create an API culture?

Plan Ahead! Don’t Build an API Superhighway into a Cul-de-sac
: Without proper planning, a business can start their API initiatives, build incredible excitement quickly, but find that the path they have taken leads them into a cul-de-sac (or dead end) that cannot handle the demand they have created.

IBM API Connect v10.x Deployment WhitePaper
: A technical deep dive on the deployment options for IBM API Connect.

Principles for API Security - White Paper
: API security is of paramount importance in gaining the promised benefits without exposure to negative consequences.

Can you trust your APIs?
: As enterprises are continuously expanding their digital footprint, they must ensure the API behavior is intact, as it has a far-reaching effect on an application's execution and end-user experience.

Istio Service Mesh and APIConnect/DataPower Gateway integration
: What is Istio, and how can DataPower API Gateway integrate in an Istio Service Mesh.

Best Practice – Monetizing API Products
: Ultimately the goal for almost all API initiatives is Monetization in the broad sense that crosses multiple modes from Free - to Indirect - to Direct. Most businesses using APIs successfully are monetizing APIs by speeding offerings to market, reaching new markets and new customers, innovating, and sharing assets better inside their enterprise.

Tutorials

These tutorials guide you through the steps typically required to set up, configure and run an API Connect cloud.

Introduction

These tutorials are arranged according to the desired goal, such as creating and publishing an API, or managing catalogs of products, or consuming published API products. These goals can be grouped into categories as follows.

Table 1. Tutorial Categories

Category	Description
Cloud Administration	Setting up and configuring the API Connect cloud, including the creation of Provider Organizations.
API Provider Administration	Setting up and managing catalogs, inviting organization members (such as developers), creating Developer Portals, managing resources.
API Product Promotion and Usage	Managing the Developer Portal presentation and user administration, as well as consuming published API products as an external developer.

Time required

Each tutorial should take approximately 20 - 30 minutes to finish. If you explore other concepts that are related to this tutorial, it might take longer.

Use the links in the following sections to access the tutorials that fit your goals.

Cloud Administration

Table 2. Cloud Administration Tasks. Setting up and configuring the API Connect cloud, including the creation of Provider Organizations.

Category	Tutorials
Initial Configuration	• Initial Cloud Configuration
Provider Organization	• Creating a Provider Organization

API Provider Administration

Table 3. API Provider Tasks. Setting up and managing catalogs, inviting organization members (such as developers), creating Developer Portals, managing resources.

Category	Tutorials
Developer Portal Set Up	• Creating the Portal • Register a Consumer Application

API Product Promotion and Usage through the Developer Portal

There are many tutorials available for the Developer Portal from getting started to advanced customization. For more information, see Developer Portal tutorials.

Prerequisites

- You must have a web browser available, whether you are working online or offline.
- When publishing Products in any of the tutorials you must have the permissions of an Organization Manager or Administrator. However, you can complete several of the tutorials with fewer permissions. For more information about user roles, see Administering user access.

Installing and maintaining IBM API Connect

To ensure that your IBM® API Connect cloud functions, your cloud must have the necessary system requirements to support the installation. During the installation process, the components of IBM API Connect can be configured to satisfy your requirements.

Note: For a comprehensive technical guide to best practices, considerations, and deployment options for API Connect, see the IBM API Connect v10.x Deployment WhitePaper .

- **Kubernetes, OpenShift, and Cloud Pak for Integration**
  Use the instructions in this section to install, upgrade, and maintain API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.
- **VMware**
  Use the instructions in this section to install, upgrade, and maintain API Connect on VMware.
- **Migrating v5-compatible APIs to API Gateway**
  Use the migration utility to automate the migration of v5-compatible APIs to DataPower API Gateway APIs.
- **Migrating from v10 to v10 on a different form factor**
  Migrate an API Connect v10 deployment from one form factor to a different form factor.
- **The API Connect operations tool: apicops**
  Use the apicops operations tool to check the health, troubleshoot, and run maintenance operations on your API Connect installation.

- **Using Config Sync to replicate consumer-side catalog data**
  Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

Kubernetes, OpenShift, and Cloud Pak for Integration

Use the instructions in this section to install, upgrade, and maintain API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.

- **Planning your deployment**
  Review the following topics to plan your API Connect deployment.
- **Installing API Connect**
  Use these instructions to install a deployment of API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.
- **Upgrading API Connect**
  Upgrade API Connect on Kubernetes and OpenShift platforms to a newer version.
- **Maintaining API Connect**
  You can use utilities to complete maintenance tasks such as backup, restore, and certificate management on Kubernetes.
- **Uninstalling API Connect**
  You can uninstall a Kubernetes deployment of API Connect.

Planning your deployment

Review the following topics to plan your API Connect deployment.

- **Prerequisite skills for administering API Connect**
  The background knowledge and skills that are required to install and manage an API Connect deployment.
- **Key concepts: Custom Resources, Operators, and Operands**
  API Connect uses Custom Resources (CRs) and the Kubernetes Operator pattern.
- **Deployment overview for endpoints and certificates**
  When deploying API Connect, you must define endpoints for the subsystems. TLS certificates are automatically generated for all endpoints, but you can configure custom certificates for the user-facing endpoints.
- **Deployment profiles, topologies, and strategies**
  Review the available deployment topologies, profiles, and strategies for high-availability and disaster recovery, and choose the best option for your organization.
- **Kubernetes ingress controller prerequisites**
  Describes the prerequisite settings for the ingress controller for a Kubernetes runtime environment.
- **Persistent Volume (PV) requirements**
  Review the persistent volumes (PVs) required by your API Connect installation.
- **Load balancer configuration**
  When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect Kubernetes deployment.
- **Firewall requirements**
  Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on Kubernetes or OpenShift.
- **Planning your analytics deployment**
  Plan your API Connect analytics deployment by reviewing options for deployment profile and estimating required persistent storage space.
- **Key Concepts: Cert-manager, Issuers, and Secrets**
  By default API Connect uses an open source product that is called cert-manager to handle the issuing and renewal of the certificates that are used by API Connect. The cert-manager has its own Kubernetes pods and runs in its own namespace. The cert-manager adds some additional resources to the Kubernetes environment. The API Connect administrator needs to be familiar with these additional resources:
- **Webhooks deployed and managed by the API Connect Operator**
  The API Connect Operator deploys and manages various Kubernetes API webhooks in the cluster to assist in management of its custom resources.
- **Administering API Connect in your container environment**
  How to manage your API Connect subsystems in Kubernetes and OpenShift environments.

Prerequisite skills for administering API Connect

The background knowledge and skills that are required to install and manage an API Connect deployment.

The following list provides an idea of the concepts and technologies that the API Connect administrator should be familiar with:

- The container platform where API Connect is to be installed, either:
  - Kubernetes
  - OpenShift

  How to manage pods, PVCs, namespaces in your container platform.
- Linux: File permissions, editing files with the vi editor, redirecting command output to file.
- Network concepts: FQDNs, ports, firewalls.
- TLS: CAs, certificate chains, mTLS.

The examples in this list do not include all background knowledge that is required, but are intended to give a general idea of the skills that are needed to plan, install, and maintain an API Connect deployment.

Key concepts: Custom Resources, Operators, and Operands

API Connect uses Custom Resources (CRs) and the Kubernetes Operator pattern.

- Kubernetes: https://kubernetes.io/docs/concepts/extend-kubernetes/operator/
- OpenShift: https://developers.redhat.com/articles/2021/06/11/kubernetes-operators-101-part-1-overview-and-key-features.

Below are some key points to understand about how API Connect implements this pattern:

- An API Connect instance is composed of two main operators and the API Connect subsystems that they manage, which in Kubernetes terminology are known as the Operands.
- The operator is responsible for monitoring the API Connect operands, ensuring that they are running as expected.
- API Connect operands can continue running without their operator, in an unmanaged state. However, this is not a supported configuration.
- The API Connect operator manages the Management Server, Portal, and Analytics subsystems. On Kubernetes each of these subsystems has its own Custom Resource, so each of these is an Operand. On Openshift and Cloud Pak for Integration there is also the option of having a top-level Custom Resource which manages all subsystems as a single Operand.
- The DataPower operator manages the Gateway operand.
- A single API Connect operator can manage multiple API Connect instances if the operator is installed globally and the API Connect operands are in individual namespaces. This is the recommended configuration where multiple API Connect instances are required, as opposed to a separate operator in each namespace.
- There can be only one instance of the API Connect operator in your Kubernetes or OpenShift environment. You cannot have multiple namespaces each with their own API Connect operator.

Deployment overview for endpoints and certificates

When deploying API Connect, you must define endpoints for the subsystems. TLS certificates are automatically generated for all endpoints, but you can configure custom certificates for the user-facing endpoints.

Configuring endpoints

The endpoints are defined for each subsystem during installation. See Installing API Connect.

Subsystem	Endpoints	Description	Certificates
Management	admin	Endpoint on the management server for communication with the Cloud Manager user interface.	cloud-admin-ui
	manager	API Manager URL endpoint on the management server for communication with the API Manager user interface.	api-manager-ui
	consumer	Platform REST API endpoint for running consumer APIs on the management server.	consumer-api
	api	Platform REST API endpoint for running admin and provider APIs on the management server.	platform-api
	consumer catalog	Consumer Catalog URL endpoint on the management server for communication with the Consumer Catalog UI.	consumer-catalog
	hub	Automated Testing Behavior API endpoint. External Ingress, port 443	hub-endpoint
Portal	api.portal	Corresponds to Management Endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS.	mutual TLS
	portal	Portal Web site URL entered in Cloud Manager. Used publicly to access Portal.	portal-www-ingress
Analytics	ai	The analytics-ingestion endpoint is used by the Gateway service to push data to the Analytics service. Requires a TLS profile configured with mutual TLS.	mutual TLS
Gateway	rgwd (API Gateway) gwd (v5-compatible Gateway service)	This is the endpoint the gateway uses for network communication. Enter this endpoint as the Management Endpoint entered in Cloud Manager.	apic-gw-service-ingress

Configuring certificates

The certificates are configured automatically by cert-manager. The certificates for the user-facing endpoints can be customized, see Customizing user-facing certificates.

Configuring mutual TLS

Mutual TLS is used for communication between API Connect subsystems. Configure inter-subsystem communication in your TLS profiles in the Cloud Manager UI. See Creating a TLS Server Profile.

Configuring a proxy

If a Developer Portal is deployed externally to the management server zone, it does not have access to the consumer and product APIs. You need to configure a proxy to enable communication. For more information, see Configuring a proxy.

Deployment profiles, topologies, and strategies

Review the available deployment topologies, profiles, and strategies for high-availability and disaster recovery, and choose the best option for your organization.

- **Deployment and component profiles**
  Decide on whether to deploy three replica or one replica API Connect subsystems, and the memory and CPU resources to allocate to the subsystems.
- **Multiple data center deployment strategies**
  Strategies for deploying API Connect across multiple data centers.
- **OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration**
  You can install API Connect subsystems separately by using individual subsystem CRs, or you can deploy them all together with a top-level CR. You can also deploy API Connect as part of Cloud Pak for Integration. The differences between each installation type are described in this topic.

Deployment and component profiles

Decide on whether to deploy three replica or one replica API Connect subsystems, and the memory and CPU resources to allocate to the subsystems.

API Connect is composed of three components: Management, Portal, and Analytics, and a supporting program: the DataPower Gateway, see API Connect components.
Note: Throughout this document, the DataPower Gateway supporting program is also referred to as a "component" or a "subsystem". The Management, Portal, and Analytics components are also referred to as "subsystems".
The Management, Portal, Analytics, and Gateway each have a set of capacity and HA profiles, called component profiles. OpenShift and Cloud Pak for Integration also have API Connect deployment profiles that define the component profiles that are used by each component of a complete API Connect deployment.

The naming convention of the profiles is `nAxcB.mC` where:

- **nA** indicates the number (A) of replicas of each pod, where each replica must run on a different worker node.
- **cB** indicates the minimum number of virtual cores (B) required on the worker node to deploy the profile.
- **mC** indicates the minimum amount of memory (C) in GB required by the profile on the worker node.

Component profiles

Each API Connect component has a defined set of profiles that it can be deployed with. For information on the resource settings defined for each component profile, see Component profiles, CPU limits, memory limits, and licensing.

Key points of component profiles:

- One replica profiles are denoted by `n1`, and provide a single replica of each pod. The one replica profiles can be deployed on a single worker node.
- Three replica profiles are denoted by `n3`, and provide three replicas of each pod. At least three worker nodes must be available to deploy a three replica profile. If one replica pod fails, then the other two replicas continue serving requests, providing high availability.
- Component profiles do not have to be the same for each component. For example, you can have a three replica deployment of the Management component that is configured with a one replica deployment of the Portal component.
- It is possible to change component profile after installation see Advanced configuration.
- Multiple Portal, Analytics, and Gateway component instances can be added with either configuration. For example, you can have a three replica Management component that is configured with two Portal services: a one replica Portal component, and a three replica Portal component.

OpenShift and Cloud Pak for Integration API Connect deployment profiles

API Connect deployment profiles define a complete API Connect deployment, specifying the component profiles for the Management, Portal, Analytics, and Gateway components to be used in that deployment.

Key points of API Connect deployment profiles:

- The API Connect deployment profiles apply to top-level CR installations only. If you want to deploy your API Connect components individually, then select the component profiles from Component profiles, CPU limits, memory limits, and licensing. For more information about the top-level CR installation, see OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration.
- The API Connect deployment profile is selected by the user in the installation steps on OpenShift and Cloud Pak for Integration.
- API Connect deployment profiles provide one instance of the Portal, Analytics, and Gateway components.
- For details of each API Connect deployment profile, see: API Connect deployment profiles for OpenShift and Cloud Pak for Integration

- **API Connect deployment profiles for OpenShift and Cloud Pak for Integration**
  Details of the API Connect deployment profiles that are provided for OpenShift and Cloud Pak for Integration.
- **Component profiles, CPU limits, memory limits, and licensing**
  Available component profiles, their CPU and memory limits, and how the CPU-based licensing works.

API Connect deployment profiles for OpenShift and Cloud Pak for Integration

Details of the API Connect deployment profiles that are provided for OpenShift and Cloud Pak for Integration.

API Connect provides various profiles to suit your capacity and availability requirements.

The API Connect deployment profiles provide one Management component instance, and one instance of the Portal, Analytics, and Gateway components.

On Cloud Pak for Integration:

- The available deployment profiles are presented as tiles in the Platform UI.
- The Portal, Analytics, and Gateway components are automatically registered with the Management component during installation.

n1xc7.m48: Small - One replica

Best suited for light, noncritical workloads such as small team development and testing. Deploys 1 replica of the Management, Developer Portal, Analytics, and Gateway components with a minimal footprint.

Table 1. n1xc7.m48

Component name	Component profile
Management	n1xc2.m16
Portal	n1xc2.m8
Analytics	n1xc2.m16
Gateway	n1xc1.m8

n1xc16.m72: Medium - One replica

Ideal for medium workloads such as organizational development, testing, and production when in alignment with business availability requirements. Deploys 1 replica of the Management, Developer Portal, Analytics, and Gateway components.

Table 2. n1xc16.m72

Component name	Component profile
APIM	n1xc4.m16
Portal	n1xc4.m16
Analytics	n1xc4.m32
Gateway	n1xc4.m8

n1xc12.m64: Medium - One replica - Remote Gateway

Ideal for medium workloads such as organizational development, testing, and production when in alignment with business availability requirements. Must be configured for use with existing or independently deployed Gateways. Deploys 1 replica of the Management, Developer Portal, and Analytics components.

Table 3. n1xc12.m64

Component name	Component profile
APIM	n1xc4.m16
Portal	n1xc4.m16
Analytics	n1xc4.m32

n3xc16.m64: Large - Three replicas

Ideal for heavy workloads when business requires redundancy for greater availability & capacity. Deploys 3 replicas of the Management, Developer Portal, Analytics, and Gateway components.

Table 4. n3xc16.m64

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m32
Gateway	n3xc4.m8

n3xc12.m56: Large - Three replicas - Remote Gateway

Ideal for heavy workloads when business requires redundancy for greater availability & capacity. Must be configured for use with existing or independently deployed Gateways. Deploys 3 replicas the Management, Developer Portal, and Analytics components.

Table 5. n3xc12.m56

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m32

Deprecated profiles

The API Connect deployment profiles presented here existed in previous releases, but are now in a deprecated state and should not be used for new installations.

Table 6. n3xc11.m48
DEPRECATED

Component name	Component profile
APIM	n3xc2.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16
Gateway	n3xc1.m8

Table 7. n3xc14.m48
DEPRECATED

Component name	Component profile
APIM	n3xc2.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16
Gateway	n3xc4.m8

Table 8. n1xc10.m48
DEPRECATED

Component name	Component profile
APIM	n1xc2.m16
Portal	n1xc2.m8
Analytics	n1xc2.m16
Gateway	n1xc4.m8

Table 9. n3xc16.m48
DEPRECATED

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16
Gateway	n3xc4.m8

Table 10. n3xc12.m40
DEPRECATED

Component name	Component profile
APIM	n3xc4.m16
Portal	n3xc4.m8
Analytics	n3xc4.m16

Component profiles, CPU limits, memory limits, and licensing

Available component profiles, their CPU and memory limits, and how the CPU-based licensing works.

API Connect is licensed based on the CPU usage of your deployment. Each component profile sets specific CPU and memory limits on each of the containers that comprise API Connect.

API Connect operator

The API Connect operator container uses the same CPU and memory requests and limits for all profiles, and is not a container that requires license entitlement.

Table 1. Operator container CPU and memory requirements

Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits	PVC Size	Number of replicas	License entitlement required
ibm-apiconnect	ibm-apiconnect	75	1000	128	1Gi		1	No

The CPU and memory usage tables for each API Connect component profile are shown in the following pages.

- **Management subsystem deployment profile limits**
  Review the CPU, memory limits, and PVC space that are required for each management profile.
- **Portal component deployment profile limits**
  The CPU and memory limits that are defined for each Portal deployment profile.
- **Analytics component deployment profile limits**
  The CPU and memory limits that are defined for each analytics deployment profile.
- **DataPower gateway deployment profile limits**
  The CPU and memory limits that are defined for each Gateway deployment profile.

Management subsystem deployment profile limits

Review the CPU, memory limits, and PVC space that are required for each management profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: `<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>`. For example, for the `n3xc2.m16` profile:

- The three licensed containers are `apim`, `postgres`, and `taskmanager`.
- These three containers have CPU limits of 625, 750, and 625.
- This profile is a three replica (n3) profile.

The total CPU limit of the licensed containers then is: (625 + 750 + 625) * 3 = 6000

All management subsystem deployment profiles have job pods that complete tasks during startup, upgrade, backup, and restore operations. The job pods do not have any licensed containers, and their CPU/memory requests and limits are the same for all profiles.

Table 1. Management job pods CPU and memory requirements

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
management-up-apim-schema	management-up-apim-schema-0-to-<nnn>-<xx>-<yy>	apim-schema	50 m	500 m	128 Mi	256 Mi
management-up-apim-data-populate	management-up-apim-data-populate-0-to-<nnn>-<xx>-<yy>	apim-data-populate	50 m	600 m	256 Mi	4096 Mi

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
management-up-lur-schema	management-up-lur-schema-0-to-<nnn>-<xx>-<yy>	lur-schema	50 m	500 m	128 Mi	256 Mi
management-up-lur-data-populate	management-up-lur-data-populate-0-to-<nnn>-<xx>-<yy>	lur-data-populate	50 m	500 m	128 Mi	256 Mi
management-apim-restore-<xxx>	management-apim-restore-<xxx>-<yyy>	apim-restore	50 m	500 m	128 Mi	256 Mi
management-up-compliance-schema	management-up-compliance-schema-0-to-<nnn>-<xx>-<yy>	compliance-schema	50 m	500 m	128 Mi	256 Mi
management-up-compliance-data-populate	management-up-compliance-data-populate-0-to-<nnn>-<xx>-<yy>	compliance-data-populate	50 m	500 m	128 Mi	256 Mi

The following tables show the pod resource and license requirement for each management component deployment profile. A separate table shows the requirements for optional features.
Important: The tables for the three replica profiles show the usage for a single replica in the three replica deployment. Except for containers that are indicated to be one replica, multiply by three to get the total usage.

n1xc2.m16

Table 2. n1xc2.m16 profile resource and licensing requirements

Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits	PVC Size	Number of replicas	License entitlement required

Portal component deployment profile limits

The CPU and memory limits that are defined for each Portal deployment profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: **`<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>`**

All Portal component deployment profiles have a **`sync-backup`** job pod that completes tasks that are related to scheduled portal backups. The **`sync-backup`** job pod does not have any licensed containers, and its CPU/memory requests and limits are the same for all profiles.

Table 1. Portal job pods resource and licensing requirements

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
<portal-instance-name>-sync-backup	*<portal-instance-name>*-sync-backup-*<jobuuid>*	sync-ptl-backup-schedule	1m	1m	100Mi	100Mi

Analytics component deployment profile limits

The CPU and memory limits that are defined for each analytics deployment profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: **<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>**

All analytics component deployment profiles have an **osinit** job pod that is run on startup and completes tasks that are related to initialization. The **osinit** job pod does not have any licensed containers, and its CPU/memory requests and limits are the same for all profiles.

You can choose different storage types with the three replica profiles, and so the pods deployed differ depending on the storage option chosen: Analytics storage type. If you choose storage type **shared**, then your analytics deployment has 1 storage pod, called **storage**. If you choose storage type **dedicated**, then your analytics deployment has 2 storage pods, called **storage** and **storage-os-master**. The tables for the three replica profiles indicate in parentheses after the pod name which storage type the pod applies to, for example "storage (shared)".

Table 1. Analytics job pods

Job Name	Pod Name	Container Name	CPU Requests	CPU limits	Memory Requests	Memory Limits
<analytics-instance-name>-osinit	*<analytics-instance-name>*-osinit-*<podid>*	osinit	8 m	100 m	128 Mi	256 Mi
<analytics-instance-name>-oscron	*<analytics-instance-name>*-oscron-*<jobid>*-*<podid>*	oscron	8 m	100 m	128 Mi	256 Mi

The PVC sizes that are specified in the tables are the defaults. Review the planning and installation documentation to decide on the sizes to allocate for your deployment: Planning your analytics deployment.

DataPower gateway deployment profile limits

The CPU and memory limits that are defined for each Gateway deployment profile.

The tables in this topic also show which containers require license entitlement. The sum of the CPU limits of the licensed containers, multiplied by the number of replicas determine what you are charged. The formula is: `<total licensed CPU limit> = <total CPU limits of all licensed containers> * <number of replicas>`.
Note: All profiles show PVC size as 30Gi, this is only required if the Token Management Service (TMS) is enabled. If TMS is not enabled, there is no PVC requirement.

Multiple data center deployment strategies

Strategies for deploying API Connect across multiple data centers.

If you want to deploy API Connect across multiple data centers, then several options are available and are detailed in this topic.

Note:
You can install the subsystems that make up an API Connect deployment in different data centers, but it is not recommended to install a single API Connect subsystem across data centers. For example, if you are deploying a three replica analytics subsystem, then all analytics subsystem replicas should run in the same data center. Splitting a three replica deployment across data centers is only supported when the network latency between the data centers is less than 10 ms.

For the gateway service, if TMS is required and an external OAuth provider cannot be used, then the gateways can be located in different data centers if network latency between data centers is less than 30 ms.

Remote gateway deployment

To provide high availability for your published APIs, you can deploy one or more gateway services in different data centers, and register them with the management subsystem in your main data center. If your main data center has an outage, then your remote gateways continue to process calls to your published APIs.

Remote gateway deployment is the simplest way to take advantage of multiple data centers. The main disadvantage is that you cannot update any published APIs during the main data center outage (because your management subsystem is in the main data center).

To install API Connect with remote gateways, follow the multi-namespace installation procedures for your platform:

- OpenShift: Installing API Connect subsystems in different namespaces or environments on OpenShift.
- Kubernetes: Deploying operators in a multi-namespace API Connect cluster.

Cold-standby deployment

In a cold-standby deployment, API Connect is installed and running in your main data center. In your cold-standby data center, API Connect is ready to be installed and has access to the API Connect backup files from your main data center.

If your main data center has an outage, then you install API Connect in your cold-standby data center, and restore your most recent subsystem database backups to your cold-standby deployment.

Requirements for cold-standby configuration:

- The API Connect deployment in the cold-standby data center must use the same deployment profile as the main data center.
- The API Connect network endpoints that you define in your main data center must be valid in your cold-standby data center.
  For example, if the network endpoint for your Cloud Manager UI is **`cloud-admin.apicinstall.example.com`**, this endpoint must route correctly to the management subsystem you install in your cold-standby data center.

  Every network endpoint that you configure during API Connect installation and configuration in your main data center must be valid in your cold-standby data center.

- Ensure that subsystem backups are regularly copied from your main data center to your cold-standby. Backups must include both your infrastructure configuration (CR and secret YAML files), and subsystem database backups. See Backing up, restoring, and disaster recovery.
  Note: If your cold-standy data center is unable to connect to your primary backup server due to firewall or access issues, you need to regularly copy the entire EDB directory, including hidden files, for example, .data.tar.gz.part1, .data.tar.gz.part2, from your main data center to the cold-standby.

The steps for failing over to your cold-standby data center are:

1. Install API Connect in your cold-standby data center, by using the infrastructure configuration backup YAML files from your main data center.
2. Restore your API Connect subsystem database backups.
3. Update network routing so that user traffic is directed to your cold-standby data center.

Steps 1 and 2 are essentially the same as the disaster recovery steps to restore API Connect, see Backing up, restoring, and disaster recovery.
The advantage of the cold-standby deployment over the remote gateway deployment is that your full API Connect deployment is available in the cold-standby site. Management and portal subsystem users can update APIs and view analytics data while your main site is unavailable.

Warm-standby deployment

In the warm-standby deployment, the management and portal subsystems continually replicate their databases to a warm-standby API Connect deployment in a separate data center.

The advantage of the warm-standby deployment over cold-standby is that the failover process is faster, and the management and portal databases in the warm-standby site are fully up to date. With the cold-standby strategy, your management and portal databases are only as recent as the last backup you took from your main site.

The disadvantage of the warm-standby deployment is that it adds extra complexity to the API Connect installation process, and all ongoing maintenance procedures such as upgrade. Use the warm-standby deployment strategy only when the following are essential requirements:

- Minimal management and portal subsystem downtime.
- No management and portal data loss, when restoration of data from the last backup that was taken of your active site is not sufficient.

Requirements for warm-standby configuration:

- The API Connect deployment in the warm-standby data center must use the same deployment profile as the main data center.
- The API Connect network endpoints that you define in your main data center must be valid in your warm-standby data center.
  For example, if the network endpoint for your Cloud Manager UI is **`cloud-admin.apicinstall.example.com`**, this endpoint must route correctly to the management subsystem you install in your warm-standby data center.

  Every network endpoint that you configure during API Connect installation and configuration in your main data center must be valid in your warm-standby data center.

The warm-standby deployment configuration is referred to in this documentation as two data center disaster recovery (2DCDR). For more information about 2DCDR, see Two data center warm-standby deployment on Kubernetes and OpenShift.

- **Two data center warm-standby deployment on Kubernetes and OpenShift**
  An overview of the two data center disaster recovery deployment strategy with a warm-standby data center.
- **Two data center deployment examples and diagrams**
  Examples of two data centers deployment options.

Two data center warm-standby deployment on Kubernetes and OpenShift

An overview of the two data center disaster recovery deployment strategy with a warm-standby data center.

The two data center disaster recovery warm-standby deployment configuration (referred to as 2DCDR) provides continuous replication of the management and portal subsystem databases to a warm-standby deployment in another data center.
Important: The 2DCDR deployment adds complexity to the API Connect installation procedures, and all subsequent maintenance procedures such as backup, restore, and upgrade. Before you decide to use the 2DCDR deployment strategy, review the Multiple data center deployment strategies to see whether any of the alternatives are better suited to your requirements.

Key points of the two data center disaster recovery (DR) solution

- Two data center DR is an active/warm-standby deployment for the management and portal subsystem, and must use manual failover.
- Two DataPower® Gateway subsystems must be deployed to provide high availability for the gateway service. However, this scenario doesn't provide high availability for the analytics service.
- If high availability is required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.
- Data consistency is prioritized over data availability.
- Each data center must be setup within its own Kubernetes or OpenShift cluster.
- Latency between the two data centers must be less than 80 ms.
- Port 443 must be open between data centers for API Connect database replication.
- Replication of the management database is asynchronous, so it is possible that the most recent updates do not transfer to the warm-standby data center if there is an active data center failure.
- Replication of the portal database is synchronous, and therefore the latency is limited to 80 ms or less.
- The management and portal subsystems in the two data centers must use the same deployment profile.
- The deployment in each data center is effectively an instance of the same API Connect deployment - therefore, the endpoints, certificates, and Kubernetes secrets must all be the same.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a two data center disaster recovery configuration.

Deployment architecture

A two data center deployment model is optimized for data consistency ahead of data availability, and must use manual failover when a fault occurs. For high availability of management and portal subsystems ensure that you use a three replica deployment profile. For more information on deployment profiles, see: Deployment and component profiles.

For a single Kubernetes cluster to span multiple data centers the network latency must be no more than a few milliseconds, typically less than 10 ms. This low latency is often unachievable between geographically separated data centers. For this reason, the two data center disaster recovery solution requires that each data center is set up with its own Kubernetes cluster. The management and portal subsystem databases are continually replicated from the active datacenter to the warm-standby datacenter, this requires a network latency between the two data centers of less than 80 ms.

To achieve high availability for the DataPower Gateway, you must deploy two gateway subsystems. One subsystem in the active data center, and a separate subsystem in the warm-standby data center. Publish all Products and APIs to both gateway subsystems. The gateway subsystems are independent, and so are insulated if an issue occurs in one of them. A global dynamic router can then be used to route traffic to one gateway subsystem or the other. If high availability is also required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration portal analytics isn't possible.

There can be multiple portal services in an API Connect deployment (although still only one portal site per Catalog).

The deployment in each data center is effectively an instance of the same API Connect deployment – as the database is replicated, all of the configuration is also shared. Therefore, the endpoints, certificates, and secrets all need to be the same.

Dynamic routing

Note: A dynamic routing device, such as a load balancer, is required to route traffic to either data center. However, neither this device nor its configuration is part of the API Connect offering. Contact IBM Services if you require assistance with configuring a dynamic router.
The dynamic router configuration must handle the traffic between the subsystems and between the data centers. For example, the consumer API calls from the portal to the management subsystem must transfer through a dynamic router so that the portal can use a single endpoint regardless of which data center the management subsystem is active in. The same is needed for calls to the Platform and Admin APIs from the other subsystems, as well as for incoming UI traffic for the portal UI, Cloud Manager UI, and API Manager UI.

The dynamic router must support SSL passthrough, so that it routes the Mutual TLS (mTLS) connections between the management subsystem and the portal, and between the management subsystem and the DataPower Gateway. The router should not do TLS termination, it should do layer 4 based routing by using SNI.

If you do not want to use mTLS between API Connect subsystems, you can Enable JWT security instead of mTLS.

Service status

When a failure occurs, it is common practice to display an interstitial system outage web page. The dynamic router can be configured to display this web page when there is a failure, while the manual failover to the warm-standby data center is taking place.

Deployment-profiles

Both one replica and three replica deployment profiles can be used with two data center DR, but they must be the same at each data center. For more information about the deployment-profiles, see Deployment and component profiles on Kubernetes, and VMware deployment overview and requirements.

For more information about a two data center DR deployment, see the following topics:

Kubernetes and OpenShift

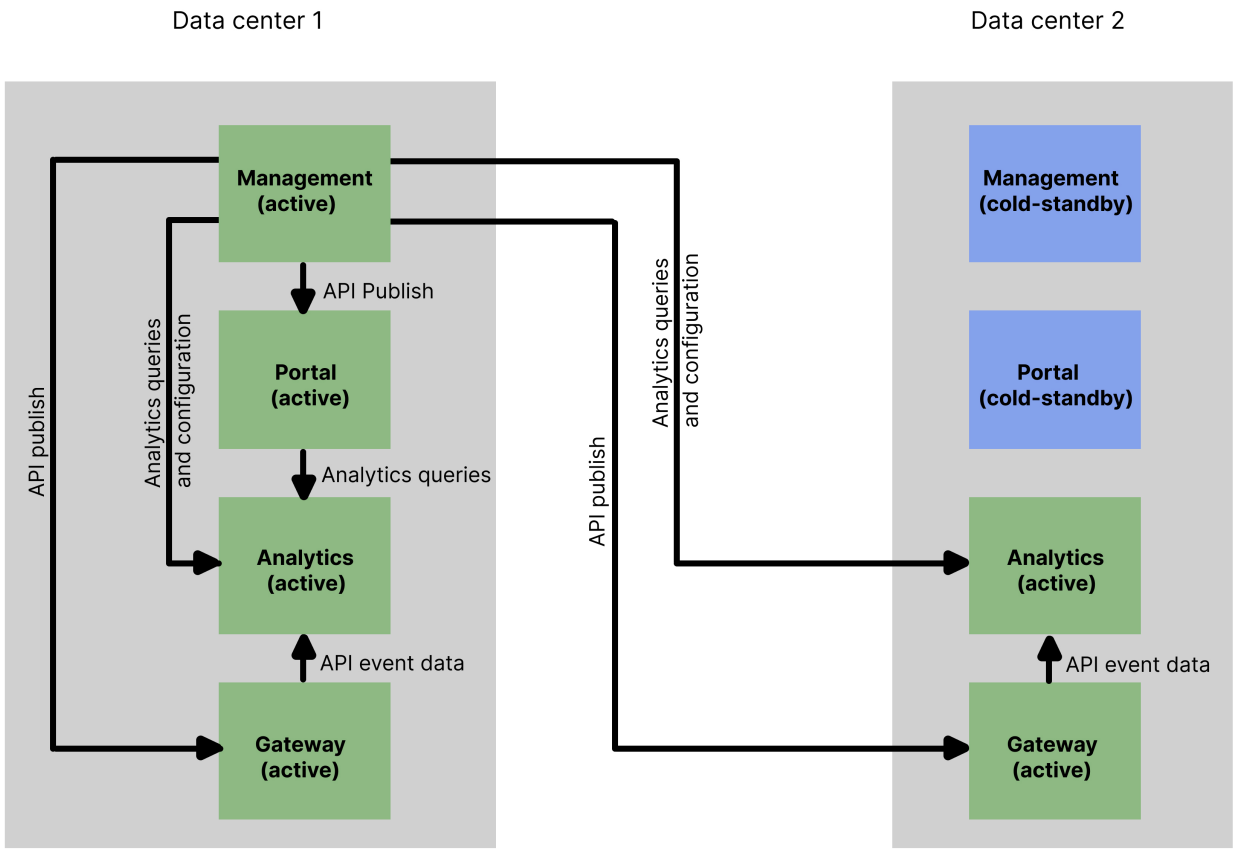
- Installing a two data center deployment on Kubernetes
  - Converting a single data center to a two data center deployment on Kubernetes
- Maintaining a two data center deployment

Two data center deployment examples and diagrams

Examples of two data centers deployment options.

The descriptions on this page refer to a deployment of API Connect across two data centers. The data centers are referred to as DC1 and DC2. API Connect subsystems in each data center are referred to as **`<subsystemname>_<dc>`**, for example: **`management_dc1`** refers to the management subsystem in DC1.

Remote gateway



With a remote gateway deployment, DC1 has a complete API Connect installation (management, portal, analytics, gateway), and DC2 has one or more gateways deployed that are registered with the management subsystem in DC1. All APIs published in DC1 are also published to the gateways in DC2. If DC1 has a failure, then the gateways in DC2 can continue processing API calls.

The steps to install and configure a remote gateway deployment are:

1. Install all API Connect subsystems in DC1.
2. Install one or more gateways in DC2.
3. In the Cloud Manager UI, register your DC2 gateways with **`management_dc1`**.
4. Associate your **`analytics_dc1`** subsystem with **`gateway_dc1`** and **`gateway_dc2`**.
5. Provider organization owners must configure all catalogs to publish to both **`gateway_dc1`** and **`gateway_dc2`**.

Cold-standby

In the cold-standby topology, all API Connect subsystems are installed normally in DC1. In DC2 the analytics and gateway subsystems are installed and running, but the management and portal subsystems are in a ready-to-install state (cold-standby). If a failure occurs in DC1, then the management and portal subsystems in DC2 are installed, and the latest database backups from the DC1 management and portal subsystems are restored to them.

Key points of the cold-standby topology:

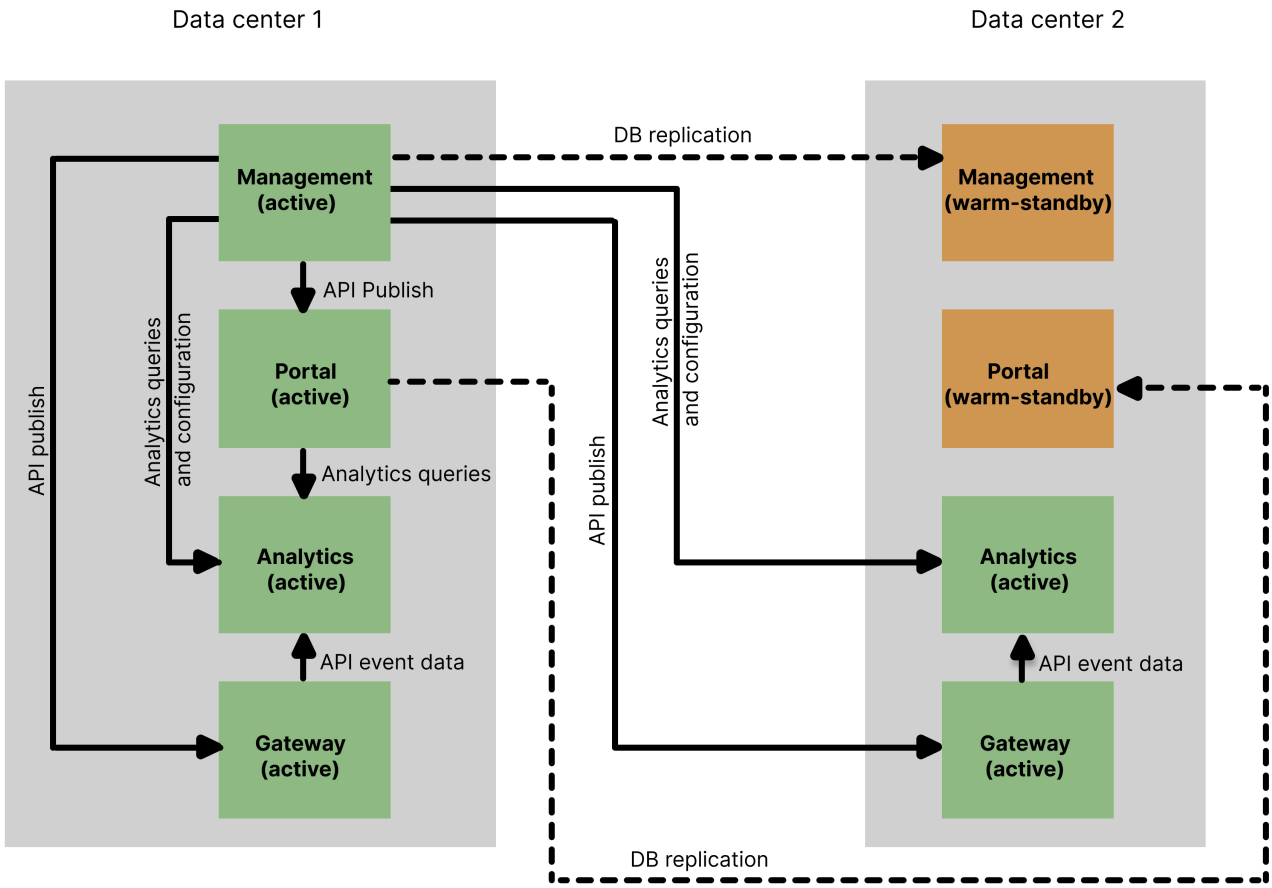
- During a failure of DC1, **`gateway_dc2`** continues to process API calls. Configure your load-balancer to direct all calls to **`gateway_dc2`** if **`gateway_dc1`** stops responding.
- Ensure that the latest management and portal subsystem backups are accessible from DC2. This includes your infrastructure configuration backups, and your database backups. See Backing up, restoring, and disaster recovery.
- The recovery point for the management and portal subsystems is the last time a backup of these subsystems was taken. If you have a low recovery point objective (RPO) for management and portal, then schedule frequent backups.
- Portal sites cannot show analytics data from either data center.

The installation and configuration procedure for cold-standby is:

1. Install all API Connect subsystems in DC1.
2. Prepare the API Connect installation in DC2, but do not install the management and portal subsystems. Install only the API Connect operator, the gateway, and the analytics subsystems in DC2.
3. Copy the **`ingress-ca`** secret from DC1 to DC2. See Synchronizing the ingress-ca certificates between sites.
4. In the Cloud Manager UI in DC1, register the DC1 subsystems and also the DC2 gateway and analytics subsystems. Associate **`analytics_dc2`** with **`gateway_dc2`**.
5. In the API Manager UI in DC1, configure all catalogs to use both **`gateway_dc1`** and **`gateway_dc2`**. Ensure that all products are published to both gateway services.
6. Configure scheduled backups of your management and portal subsystems in DC1, at a frequency sufficient for your recovery point objective. Ensure that backups are copied to a location that is accessible from DC2.
7. Configure your load-balancer to route all API traffic to **`gateway_dc2`** if **`gateway_dc1`** fails to respond.

The failover procedure for cold-standby, where all subsystems in DC1 are unavailable is:

1. Ensure that all API Connect traffic is directed to DC2.
2. Install the management and portal subsystems in DC2.
3. Restore the management and portal subsystem databases in DC2, with the most recent backups taken from DC1.



Reverting to DC1 after recovery:

- Ensure that you have recent backups from management and portal in DC2.
- Restore the recent DC2 database backups to the management and portal subsystems in DC1. If you modified any of the subsystem YAML files or certificates while running management and portal in DC2, then make those same updates on DC1.
- Update your network configuration to route management and portal traffic to DC1.
- Uninstall the management and portal subsystem from your cold-standby data center. See Uninstalling API Connect subsystems.

If you want to be able to see analytics data from both data centers in the Cloud Manager and API Manager UIs, then see Replicating analytics data to a remote data center.

Warm-standby with analytics in both data centers

The management and portal subsystems are deployed in both data centers using the active/warm-standby configuration: Two data center warm-standby deployment on Kubernetes and OpenShift. An analytics subsystem is deployed in each data center to receive API event data from the gateways in that data center. Unlike the management and portal subsystems in the warm-standby data center, the gateway and analytics subsystems are running and communicate with the management subsystem in the active data center.

The steps to install the 2DCDR warm-standby deployment are:

1. Follow the installation instructions for 2DCDR on your platform: Installing API Connect. Install the management and portal subsystems as active in DC1, and as warm-standby in DC2.
2. Install gateway and analytics subsystems in both data centers.
3. In the Cloud Manager UI of DC1, register all gateways and analytics subsystems from both data centers. Associate `analytics_dc1` with `gateway_dc1`, and `analytics_dc2` with `gateway_dc2`.
4. Provider organization owners must set all catalogs to publish to both `gateway_dc1` and `gateway_dc2`.
5. API calls can be directed to both `gateway_dc1` and `gateway_dc2`, and the API events they log are sent to the analytics subsystems that they are associated with.

Failover steps if DC1 fails:

1. Promote `management_dc2` and `portal_dc2` to active.
2. Direct all API Connect traffic to DC2.
3. New APIs that are published are sent to `gateway_dc2`, and queued for `gateway_dc1`.

If you want to be able to see analytics data from both data centers in the Cloud Manager and API Manager UIs, then see Replicating analytics data to a remote data center.

Advanced deployment scenarios

For more advanced multi-data center deployment options, see the API Connect white paper: IBM API Connect v10.0.8.x WhitePaper.

OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration

You can install API Connect subsystems separately by using individual subsystem CRs, or you can deploy them all together with a top-level CR. You can also deploy API Connect as part of Cloud Pak for Integration. The differences between each installation type are described in this topic.

Before you review this topic, make sure that you understand the Key concepts: Custom Resources, Operators, and Operands of API Connect.

Deploying with individual subsystem CRs

Deploying API Connect using individual subsystem CRs means that you must install each subsystem separately, either with the OpenShift UI, or by manually applying YAML files for each subsystem. The portal, analytics, and gateway subsystems must then be manually registered with the management subsystem, as described in Defining your Cloud Manager topology.

Individual subsystem CRs: Key points

- Deploying with individual subsystem CRs allows more flexibility than the alternative top-level CR deployment, and can be simpler to manage.
  - Subsystems in the same API Connect cluster can be installed in different namespaces.
  - Updates to subsystem CRs are made directly in the subsystem CR. When the top-level CR is used, all configuration updates must be made in the top-level CR, which can require copying sections from the subsystem CR and pasting them into the top-level CR.
  - Custom certificates can be used for inter-subsystem communication.
  - The two data center disaster recovery deployment topology is simpler to manage and more flexible when individual subsystem CRs are used.
- The individual subsystem CR installation is preferable for deployments where you plan to have multiple portal and analytics services, or subsystems in different namespaces, and where you do not require the other capabilities of Cloud Pak for Integration.
- Individual subsystem CR installation does not integrate as fully with Cloud Pak for Integration as the top-level CR installation. See the next section.

Deploying with the top-level CR

Deploying with the top-level CR automates the deployment of each subsystem. To install, you select 'API Connect' in either the OpenShift console or the Cloud Pak for Integration Platform UI, enter some properties such as namespace, click 'Create', and all the subsystems that make up an API Connect instance are automatically installed. You still have individual CRs for each subsystem, but they are all managed by the top-level CR. The top-level CR is called **`APIConnectCluster`**.

Top-level CR: Key points to consider

- All API Connect subsystems are managed by the top-level CR. You edit the top-level CR YAML when you want to update your API Connect configuration.
- With the top-level CR, the subsystem CRs still exist but should not be edited directly. Any changes made to them get overwritten by the top-level CR.
- Installation with the top-level CR requires fewer steps, but subsequent management of subsystems and configuration of advanced features can be more complicated than it is with an individual subsystem deployment.
- The top-level CR deployment provides one of each subsystem service: management, portal, analytics, and gateway. If you want additional portal, analytics, or gateway services, do not use the top-level CR.
- For a quick proof-of-concept demonstration, the top-level CR is ideal due to the automated installation of subsystems.
- The top-level CR deployment integrates fully with Cloud Pak for Integration. For top-level CR installation instructions on Cloud Pak for Integration, see *Deploying an instance by using the Platform UI* and *Deploying all API management subsystems by using the CLI* in the Cloud Pak for Integration documentation.

Deploying with Cloud Pak for Integration

Cloud Pak for Integration includes API Connect as one of its many capabilities. For information on everything Cloud Pak for Integration provides, see https://www.ibm.com/docs/en/cloud-paks/cp-integration.

Key points of a Cloud Pak for Integration API Connect installation:

- Cloud Pak for Integration provides a UI, called the Platform UI, which can be used to install and manage your API Connect deployment.
- When installing API Connect with the Cloud Pak for Integration Platform UI, the top-level CR deployment is used. All the same key points of the top-level CR apply to Cloud Pak for Integration installations that use the top-level CR.
- If Cloud Pak for Integration is already installed in your environment, and you install API Connect with the Cloud Pak for Integration Platform UI, then API Connect automatically incorporates and attempts to use Cloud Pak features.
  You can prevent Cloud Pak for Integration incorporating your API Connect installation by setting **`metadata.annotations.apiconnect-operator/cp4i`** to **`false`** in the top-level CR before installation.

  If you are not installing API Connect with the Cloud Pak for Integration Platform UI and you want your API Connect deployment incorporated with Cloud Pak for Integration, then you can set the API Connect **`metadata.annotations.apiconnect-operator/cp4i`** annotation to **`true`** in your top-level CR (or management CR if not using the top-level CR) before installation.

  It is not possible to change the value of **`metadata.annotations.apiconnect-operator/cp4i`** after installation. If you want to do this, then you must reinstall API Connect.

- It is not possible to uninstall Cloud Pak for Integration and retain any API Connect instance that it is managing. Nor can a Cloud Pak for Integration API Connect instance be converted to a stand-alone instance. If you want to change to a non-Cloud Pak for Integration deployment, see Migrating from v10 to v10 on a different form factor.
- You can migrate an existing top-level CR installation to be incorporated into Cloud Pak for Integration. See see Migrating from OpenShift to Cloud Pak for Integration on the same cluster.
  Note: The reverse of this operation is not supported.

- In a Cloud Pak for Integration installation, if the Platform UI is detected and the top-level CR deployment is used, the API Connect operator runs a job that is called the `configurator`, which registers all API Connect subsystems with the management service after installation. This means that your API Connect installation is ready for you to immediately start configuring provider organizations.
- Cloud Pak for Integration does mean a higher computing resource requirement in your environment, when compared to a stand-alone API Connect installation.
- The planning requirements for API Connect such as available PVs and Firewall settings that are described in Planning your deployment, also apply when you install API Connect with Cloud Pak for Integration.

Which deployment type should you choose?

For long-term ease of maintenance and maximum flexibility, choose Deploying with individual subsystem CRs.

For integration with the App Connect, Asset Repo, Platform UI, and other Cloud Pak for Integration features, choose Deploying with Cloud Pak for Integration.

For quick installation of API Connect that is suitable for demonstrations and testing, choose Deploying with the top-level CR.

Network requirements for inter-subsystem communication

Plan how to secure the network communications between your API Connect subsystems.

API Connect provides various configuration options that are related to inter-subsystem communication.

Support load-balancer TLS termination by disabling mTLS and enabling JWT security

If your network infrastructure requires that load-balancers implement TLS termination, then mTLS between API Connect subsystems can be disabled and JSON Web Token (JWT) security can be used instead.
Note: Although mTLS is disabled, the network communication is still secured with standard TLS, which does not require passthrough to be enabled on load-balancers.
The following communication flows can be secured with JWT:

- Management initiated communication to portal, analytics, and gateway subsystems.
- Analytics ingestion: The flow of API event records from the gateway to the analytics subsystem.
  Note: If the gateway is under a high transaction load and sending many API events to the analytics subsystem, the enablement of JWT might impact the performance of your analytics subsystem. It is recommended to run performance tests under your expected analytics load before you decide to use JWT for the analytics ingestion path.

With JWT enabled, the portal, gateway, and analytics subsystems verify the JSON Web Token (JWT) sent from the management subsystem when it initiates communication with them. The analytics subsystem verifies the JWT sent from the gateway with incoming API event data. The subsystems that receive the token contact a JSON Web Key Set (JWKS) URL to verify it. The JWKS URL is hosted by the management subsystem, in a subpath of the management subsystem's platform REST API.
For more information about this feature, see Enable JWT security instead of mTLS.

Use services instead of routes (OpenShift) or ingresses (Kubernetes)

Note: This feature is available on Kubernetes and OpenShift deployments where the API Connect subsystems are within the same cluster. It is not available on two data center disaster recovery deployments: Two data center warm-standby deployment on Kubernetes and OpenShift.
For inter-subsystem communication, API Connect uses routes on OpenShift and Ingresses on Kubernetes. Both routes and ingresses require the exposure of external HTTPS endpoints. On API Connect deployments where all subsystems are in the same cluster, you can use services instead of routes or ingresses for inter-subsystem communication. When API Connect is configured to use services, all inter-subsystem communications are kept within the cluster, providing greater security and reduced load on external network infrastructure such as load-balancers.

In the context of inter-subsystem communication, the use of routes or ingresses is referred to as `external` communication, and the use of services is referred to as `in-cluster` communication.

You select whether to use `external` or `in-cluster` communication when you register your portal, gateway, or analytics subsystems with the management subsystem.

For more information about this feature, see In-cluster service communication between subsystems.

Enabling mTLS on management to gateway communication

On Kubernetes and on OpenShift installations where the top-level CR is not used, mTLS can be enabled for management to gateway communication. Enable mutual TLS between the management client and the gateway service's manager endpoint, add `mtlsValidateClient` to the `spec` section:

```
spec:
  mtlsValidateClient: true
```

This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under `gatewayManagerEndpoint.hosts.secretName`. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under `gateway.client.secretName`.
Note: If you do not want to use mTLS, the you must enable JWT instead.
Note: On Cloud Pak for Integration and OpenShift where the top-level CR is used, mTLS enablement for management to gateway communication is not supported.

Certificates used to secure inter-subsystem communication

TLS keystores and truststores for the management subsystem are configured in the Cloud Manager UI, see TLS profiles overview.

TLS configuration on the portal, analytics, and gateway subsystems is configured at the Kubernetes level.

For information about the default certificates that are used in the TLS and mTLS communications between subsystems, see Key Concepts: Cert-manager, Issuers, and Secrets.

Enable JWT security instead of mTLS

When and how to use JWT security instead of mTLS.

Most of the network interactions between API Connect subsystems use mTLS.The communication flows in API Connect that are secured with mTLS are as follows:

- Management to portal.
- Management to analytics.
- Management to API gateway.
- Management to v5 compatible gateway.
- Management to Event gateway. Cloud Pak for Integration only.
- API gateway to analytics.
- V5 compatible gateway to analytics.
- Event gateway to analytics.

All other inter-subsystem communication uses TLS. For the communication routes that use mTLS, it is a requirement that all network infrastructure such as load-balancers that are located between API Connect subsystems implement TLS passthrough (and not TLS termination).

Use of JSON Web Token (JWT) security instead of mTLS allows for the deployment of API Connect in network infrastructures where TLS termination is enabled on load-balancers that are located between subsystems. JWT provides application layer security between API Connect subsystems. The typical use-case for this feature is when payload inspection of all network communications is required at network boundaries. The communication flows that support JWT security are:

- Management to portal.
- Management to analytics.
- Management to API gateway.
- Management to v5 compatible gateway.
- API gateway to analytics.
  Note: It is not possible to use JWT and disable mTLS on the V5 compatible gateway to analytics message flow.

The management subsystem always sends a JWT when it initiates communication with the other subsystems, but by default the subsystems do not verify this JWT. When JWT security is enabled, the subsystems verify the JWT by making a REST call to the JSON Web Key Set (JWKS) URL. The JWKS URL is hosted on the management subsystem's platform REST API.

To enable JWT verification on management initiated communication, update the subsystem CRs to specify the JWKS URL. To disable JWT verification, update the subsystem CRs and delete the value of the JWKS URL (leave it unset).

To enable JWT verification on gateway to analytics communication, enable the Use JWT switch when you register the gateway in the Cloud Manager UI.
Note: For OpenShift users: The example steps in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR you must edit the `APIConnectCluster` CR (the top-level CR), instead of directly editing the subsystem CRs. If the subsystem section is not included in the top-level CR, copy and paste the section from the subsystem CR to the `APIConnectCluster` CR.

Disabling mTLS and enabling JSON Web Token (JWT) security

If you disable mTLS, you must enable JWT. It is not possible to configure API Connect with both mTLS and JWT disabled.

You disable mTLS on the portal, gateway (for management to gateway communication), and analytics subsystems by setting the `mtlsValidateClient` property to false in the Custom Resources (CRs) of each subsystem.

When `mtlsValidateClient` is set to false, the subsystem does not verify the client's TLS credentials, but it does check for a valid JWT configuration. For example, to disable mTLS and enable JWT for management to portal communication, edit the portal CR and set:

```
spec:
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the `jwksUrl` specified in the management subsystem CR `status.endpoints` section.

Using registration of the portal service in the Cloud Manager UI as an example, JWT works as follows:

1. Management subsystem establishes a TLS connection to the portal subsystem on the portal director admin endpoint, and sends a JWT to the portal.
2. Before the portal trusts the management subsystem, it first verifies the JWT it received. The JWT is verified by a call to a JSON Web Key Set (JWKS) URL.
3. The management subsystem receives the JWT verification request from the portal on its platform REST API, and responds that the JWT is valid.
4. The portal receives confirmation that the JWT is valid, and so it can trust the management subsystem and continue the registration process.

To disable JWT security for management initiated communication, either remove the `jwksUrl` property from the CR, or leave its value empty. If you disable JWT, you must enable mTLS by setting `mtlsValidateClient` to true.

To disable JWT security for gateway to analytics communication, disable the Use JWT switch for the registered gateway in the Topology page of the Cloud Manager UI.

Configuring the JWKS URL

The JWKS URL is defined as the platform API hostname with the following subpath appended: `api/cloud/oauth2/certs`. You can see what the JWKS URL is from the `status.endpoints` section of the management CR, for example:

```
status:
...
  endpoints:
...
```

```
    - name: jwksUrl
      secretName: api-endpoint
      type: API
      uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

Note: The JWT feature is intended for environments where the are load-balancers located between subsystems. If you are using the in-cluster communications feature Use services instead of routes (OpenShift) or ingresses (Kubernetes), then you cannot have load-balancers between subsystems, and so disabling mTLS and enabling JWT is not necessary. However, if you do want to use the JWT feature with in-cluster communications then the JWKS URL can be obtained following these steps:

1. Describe any API Connect pod:

   ```
   kubectl describe pod <apic-pod>
   ```

2. In the pod describe output, search for `APIC_PLATFORM_API_SVC_ENDPOINT`:

   ```
   Containers:
     apim:
       Environment:
         APIC_PLATFORM_API_SVC_ENDPOINT:  https://management-juhu.acme-v1005-020323.svc:2000/api
   ```

3. The JWKS URL is the value of `APIC_PLATFORM_API_SVC_ENDPOINT` with `/cloud/oauth2/certs` appended to it. If the APIC_PLATFORM_API_SVC_ENDPOINT is missing the `/api` at the end, add `api/cloud/oauth2/certs` instead. The path of the JWKS URL must always be `api/cloud/oauth2/certs`.

Key points and limitations of JWT security

- Changing the JWKS URL on portal, and analytics subsystems causes pods to restart, and so a short subsystem outage. The gateway pod does not restart when the JWKS URL is changed.
- On new installs of Cloud Pak for Integration and top-level CR OpenShift deployments, the JWKS URL is set automatically for the portal, gateway, and analytics subsystems.
- You can have both mTLS and JWT enabled, although the analytics subsystem does not verify the JWT if mTLS is enabled.
- The v5c gateway does not send a JWT to the analytics subsystem. This flow is secured by mTLS, which cannot be disabled.
- If you enable JWT for gateway to analytics communication, the ingestion of analytics data becomes dependent on the availability of the management subsystem (so that the JWT can be verified). For more information about this limitation, see: JWT usage between gateway and analytics subsystems.
- Under high analytics ingestion loads, JWT enablement might impact the performance of the analytics subsystem. It is recommended to complete a performance test under your expected analytics load before you decide to use JWT for gateway to analytics communication.

JWT usage between gateway and analytics subsystems

Because the analytics subsystem makes a REST call to the management subsystems to verify the JWT it receives from the gateway, analytics ingestion depends on the management subsystem when JWT is enabled. The analytics subsystem caches the response from the JWKS URL so that it does not need to make a REST call to the management subsystem every time API event data is received from the gateway. But the JWT verification cache does expire after 24 hours, and a new REST call to the management subsystem is made to refresh the cache. The JWT dependency on the platform REST API means that an outage of the management subsystem does eventually prevent the analytics subsystem from accepting new analytics API event records.

In-cluster service communication between subsystems

Key points and limitations of `in-cluster` inter-subsystem communication.

- In-cluster communication is only possible between subsystems that are in the same cluster.
- In-cluster communication cannot be used in two data center disaster recovery deployments, Two data center warm-standby deployment on Kubernetes and OpenShift.
- If you are adding new subsystems to an upgraded deployment you can set the subsystems to use `in-cluster` communication, but you must use different certificates and secrets for the subsystem endpoints. The default certificate and secret names for the subsystem endpoints are:
  - Analytics: `ai-endpoint`.
  - Portal: `portal-admin`.
  - Gateway: `gwv6-manager-endpoint` or `gw-gateway-manager`

  Do not use these same certificate and secret names if your additional subsystems are in the same namespace.
- If you customize any TLS certificates used for inter-subsystem communication, then to use `in-cluster` communication the TLS certificates must include the service hostname in the DNS section of the SAN, for example:

  ```
  X509v3 Subject Alternative Name: critical
                  DNS: ptladmin.mydomain.com, DNS: portal.apic.svc, DNS: portal.apic.svc.cluster.local
  ```

- On Cloud Pak for Integration, all subsystems are registered automatically during deployment with `external` communication specified.

Kubernetes ingress controller prerequisites

Describes the prerequisite settings for the ingress controller for a Kubernetes runtime environment.

Before you begin

Attention:
This document provides guidance on configuring the prerequisite settings for the ingress controller in a Kubernetes runtime environment. These settings ensure proper traffic management and secure access to applications. However, these settings are specific to standard Kubernetes deployments.

Do not configure these settings for OpenShift® or CP4I environments, as those platforms have their own built-in ingress configurations.

Note:

- This article does not apply to the IBM® DataPower® Gateway component that is a part of the IBM API Connect solution.
- This article applies to third-party software that IBM does not control. As such, the software may change and this information may become outdated.

These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes. Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure. For more information, see https://kubernetes.io.

Kubernetes/ingress-nginx ingress controller `ingress-config.yml` settings

A Kubernetes deployment for IBM API Connect requires the **kubernetes/ingress-nginx** ingress controller implementation (see https://github.com/kubernetes/ingress-nginx) with SSL passthrough enabled.

API Connect v10 does not require Helm, so it is recommended to use Helm3 for the installation of the ingress controller. Follow these steps:

1. Create a file `ingress-config.yaml` where the following values are required:
   Specify at least one SSL protocol; separate multiple protocols with a comma as shown in the example.

```
controller:
  watchIngressWithoutClass: true
  admissionWebhooks:
    enabled: false
  config:
    ssl-protocols: "TLSv1.2 TLSv1.3"
  extraArgs:
    annotations-prefix: ingress.kubernetes.io
    enable-ssl-passthrough: true
```

   You may use the following sample ingress-config.yml file to configure the ingress controller:

```
controller:
  watchIngressWithoutClass: true
  admissionWebhooks:
    enabled: false
  config:
    hsts-max-age: "31536000"
    keepalive: "32"
    log-format: '{ "@timestamp": "$time_iso8601", "@version": "1", "clientip": "$remote_addr",

  kind: DaemonSet
  name: controller
rbac:
  create: "true"
```

2. Run the commands:

```
helm3 repo add ingress-nginx https://kubernetes.github.io/ingress-nginx
helm3 repo update
helm3 install ingress-controller ingress-nginx/ingress-nginx --namespace kube-system --values ingress-config.yaml
```

Kubernetes/ingress-nginx ingress controller `config.map` settings

To ensure that the IBM API Connect services have time to start, increase the *proxy-read-timeout* and *proxy-send-timeout* values, which are in seconds, in the `kubernetes/ingress-nginx` ingress controller *config.map* to at least the following:

- proxy-read-timeout: "240"
- proxy-send-timeout: "240"

Depending on your environment, you might need to increase these further if the IBM API Connect services do not start. If there is a load balancer in front of the worker nodes, then the load balancer configuration might also need to have extended timeouts.

System and Software Requirements

The system and software requirements are described in the Software Product Compatibility Reports. See Detailed system requirements for a specific product

Persistent Volume (PV) requirements

Review the persistent volumes (PVs) required by your API Connect installation.

The PV requirements for API Connect subsystems vary according to the number of subsystem nodes that are deployed, whether you are using two datacenter disaster recovery (2DCDR) Two data center warm-standby deployment on Kubernetes and OpenShift, and other subsystem specific options.

Management subsystem

Management subsystem PV requirements depend on what database backup configuration is used, and if the API discovery feature is enabled.

Table 1. Management PV requirements

Deployment profile	Database backup	Discovery enabled	Number of PVs required
Single replica (n1)	local	yes	4
Three replica (n3)	local	yes	12
Single replica (n1)	local	no	3
Three replica (n3)	local	no	9
Single replica (n1)	sftp	yes	4
Three replica (n3)	sftp	yes	12
Single replica (n1)	sftp	no	3
Three replica (n3)	sftp	no	9
Single replica (n1)	object-store	yes	3
Three replica (n3)	object-store	yes	9
Single replica (n1)	object-store	no	2
Three replica (n3)	object-store	no	6

Gateway subsystem

Only required where **tokenManagementService** is enabled:

```
tokenManagementService:
  enabled: true
  storage:
    storageClassName: $STORAGE_CLASS
    volumeSize: 30Gi
```

Portal subsystem

Table 2. Portal PV requirements

Deployment profile	Number of PVs required
Single node (n1), one datacenter	6
Three nodes (n3), one datacenter	18
Single node (n1), two datacenter	9 per datacenter
Three nodes (n3), two datacenter	27 per datacenter
Single node (n1), two datacenter, where other datacenter is three node (n3)	13 in n1 datacenter, 23 in n3 datacenter
Three node (n3), two datacenter, where other datacenter is single node (n1)	30 in n3 datacenter, 15 in n1 datacenter

The amount of persistent storage space that is used by the developer portal depends on the following factors:

- The number of portal sites you create. Each portal site uses space in the **webVolumeClaimTemplate** and **databaseVolumeClaimTemplate** PVCs. 3 backups of each portal site are stored in the **backupVolumeClaimTemplate** PVC.
- The content that you add to your portal sites, such as custom images and documents that you attach to your sites.
- If debugging tools such as Drupal logs are enabled.

Note: In Openshift disk performance increases with disk size, for example, a 200 Gi PVC has better performance than a 30 Gi PVC. It is recommended that the **databaseVolumeClaimTemplate** is kept above 200 Gi to avoid performance issues.

Analytics subsystem

The number of PVs needed depends on if you disable local storage, and if you have backups configured.

Table 3. Analytics PV requirements

Deployment profile	Local storage disabled (ingestion only)	Local storage enabled	Local storage and backups enabled
Single node (n1)	1	2	3
Three node (n3)	3	6	9

To understand how much storage capacity your analytics subsystem needs, see Estimating storage requirements.

Load balancer configuration

When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect Kubernetes deployment.

Before you begin

Note:

- This article does not apply to the IBM® DataPower® Gateway component that is a part of the IBM API Connect solution.
- This article applies to third-party software that IBM does not control. As such, the software may change and this information may become outdated.

About this task

API Connect can be deployed on a single node cluster. In this case the ingress endpoints are host names for which the DNS resolution points to the single IP address of the corresponding node hosting a particular subsystem, and no load balancer is required. For high availability, it is recommended to have at least a three node cluster. With three nodes, the ingress endpoints cannot resolve to a single IP address. A load balancer should be placed in front of an API Connect subsystem to route traffic.

Because it is difficult to add nodes once endpoints are configured, a good practice is to configure a load balancer even for single node deployments. With the load balancer in place, you can easily add nodes when needed. Add the node to the list of servers pointed to by the load balancer and the ingress endpoints defined during installation of API Connect can remain unchanged.

To support Mutual TLS communication between the API Connect subsystems, configure the load balancer with **SSL Passthrough** and **Layer 4** load balancing. In order for mTLS to be performed directly by the API Connect subsystems, the load balancer should leave the packets unmodified, as is accomplished by Layer 4.

If you do not want to use mTLS between API Connect subsystems, you can Enable JWT security instead of mTLS.

Set endpoints to resolve to the load balancer
: When configuring a load balancer in front of the API Connect subsystems, the ingress endpoints are set to host names that resolve to a load balancer, rather than to the host name of any specific node.

Note: The example deployment in the page is a Kubernetes deployment. The same principles apply to an OpenShift deployment.

Procedure

- **Kubernetes cluster with wildcard DNS**
  In this example, API Connect is deployed to a Kubernetes cluster with three master and six worker nodes. The master nodes have the Kubernetes API server listening on port 6443. The Kubernetes API Server is used for communicating with the kubectl command line interface. Note that it is generally not necessary for the Kubernetes API server (on port 6443 in this example) to be exposed outside the cluster through the load balancer, this is just one possible setup shown here.

  The kubernetes/ingress-nginx ingress controller is deployed as a daemonset, so that every worker node in the cluster has an ingress controller pod listening on port 443. The API Connect subsystems (API Manager, Developer Portal, Analytics and Gateway) are all deployed on this same cluster.

  Note:
  - When you configure a load balancer in front of a management subsystem, specify timeouts of at least 240 seconds. Note that large deployments might need larger values.

    The default timeout is typically 50 or 60 seconds, which is not long enough to avoid **`409 Conflict`** or **`504 Gateway Timeout`** errors. The **`409 Conflict`** error can occur when the time needed to complete an operation is sufficiently long that a second request gets issued.

    For example, to specify 240 seconds when using HAProxy as a load balancer, set **`timeout client`** and **`timeout server`** to **`240000`**.

    Best practice is to ensure that the same values are specified for the timeout settings for the load balancer and for the Kubernetes ingress controller. The ingress controller timeout settings are set in the ingress controller config.map. For more information, see the **`proxy-read-timeout`** and **`proxy-send-timeout`** settings in Kubernetes ingress controller prerequisites .

  - Ensure that the load balancer is configured to support the cipher **`TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`**.
    When the Developer Portal, as a client, calls back to platform-api-endpoint or consumer-api-endpoint of the management subsystem, it sends only a single cipher in the Client Hello. The cipher is **`TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`**. The SSL Handshake will fail if this cipher is not configured (supported) on the client's load balancer.

  A host running HAProxy acts as the load balancer, with a configuration for proxies in the HAProxy configuration file such as:

```
defaults
        log     global
        mode    http
        option  httplog
        option  dontlognull
        timeout connect 5000
        timeout client  240000
        timeout server  240000
        errorfile 400 /etc/haproxy/errors/400.http
        errorfile 403 /etc/haproxy/errors/403.http
        errorfile 408 /etc/haproxy/errors/408.http
        errorfile 500 /etc/haproxy/errors/500.http
        errorfile 502 /etc/haproxy/errors/502.http
        errorfile 503 /etc/haproxy/errors/503.http
        errorfile 504 /etc/haproxy/errors/504.http

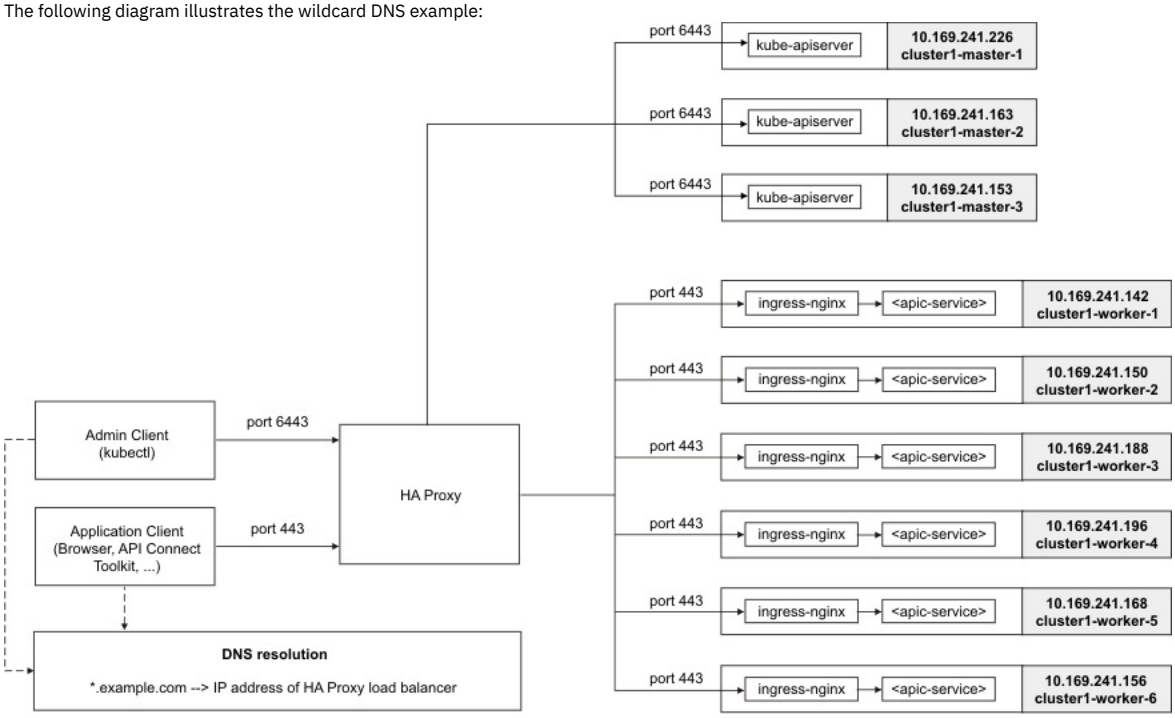
frontend apiservers
        bind *:6443
        mode tcp
        option  tcplog
        option forwardfor
        default_backend k8s_apiservers

frontend ingress
        bind *:443
        mode tcp
        option  tcplog
        option forwardfor
        default_backend k8s_ingress

backend k8s_apiservers
```

```
        mode tcp
        option  tcplog
        option ssl-hello-chk
        option log-health-checks
        default-server inter 10s fall 2
        server cluster1-master-1 10.169.241.226:6443 check
        server cluster1-master-2 10.169.241.163:6443 check
        server cluster1-master-3 10.169.241.153:6443 check

backend k8s_ingress
        mode tcp
        option  tcplog
        option ssl-hello-chk
        option log-health-checks
        default-server inter 10s fall 2
        server cluster1-worker-1 10.169.241.142:443 check
        server cluster1-worker-2 10.169.241.150:443 check
        server cluster1-worker-3 10.169.241.188:443 check
        server cluster1-worker-4 10.169.241.196:443 check
        server cluster1-worker-5 10.169.241.168:443 check
        server cluster1-worker-6 10.169.241.156:443 check
```



A wildcard DNS record allows the resolution of **`*.example.com`** to the IP address of the HAProxy host.

The ingress endpoints are defined in the CRs (custom resources) for each API Connect subsystem. During configuration of each subsystem, you define the endpoint by specifying a host name **`$STACK_HOST`** in the CR. For configuration instructions, see Installing the API Connect subsystems.

You can view the endpoint definitions in sample CRs:

- Installing the management subsystem
- Installing the developer portal subsystem
- Installing the analytics subsystem
- Installing the gateway subsystem

The following diagram illustrates the wildcard DNS example:

- **Kubernetes cluster without wildcard DNS**
  This example uses the same topology as the previous one, except that there is no wildcard DNS resolution. Instead, individual DNS records are added, all pointing to the IP address of the load balancer. For example: **`portal.example.com`** and **`admin.portal.example.com`** resolve to the IP address of the load balancer.
- **Kubernetes cluster with `xip.io` or `nip.io`**
  This example uses the same topology as the first one, except that there is no specific DNS resolution configured and instead a service such as **`xip.io`** or **`nip.io`** provides wildcard DNS resolution. It is not recommended to use this approach for a production setup, as the ingress endpoints configured during installation of API Connect would be tied to the IP address of the load balancer. This approach can be useful when configuring a test deployment in situations where access to DNS records is not practical or would introduce delay in the deployment.

Firewall requirements

Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on Kubernetes or OpenShift.

Required Ports between zones

The following network diagram example helps to explain which ports must be configured in an API Connect network. Specific ports must be configured to enable the communication between the various zones, both public and private, in a network.

The ports specified in the diagram are default ports. Check your deployment to understand which communication, if any, is configured to use non-default ports.

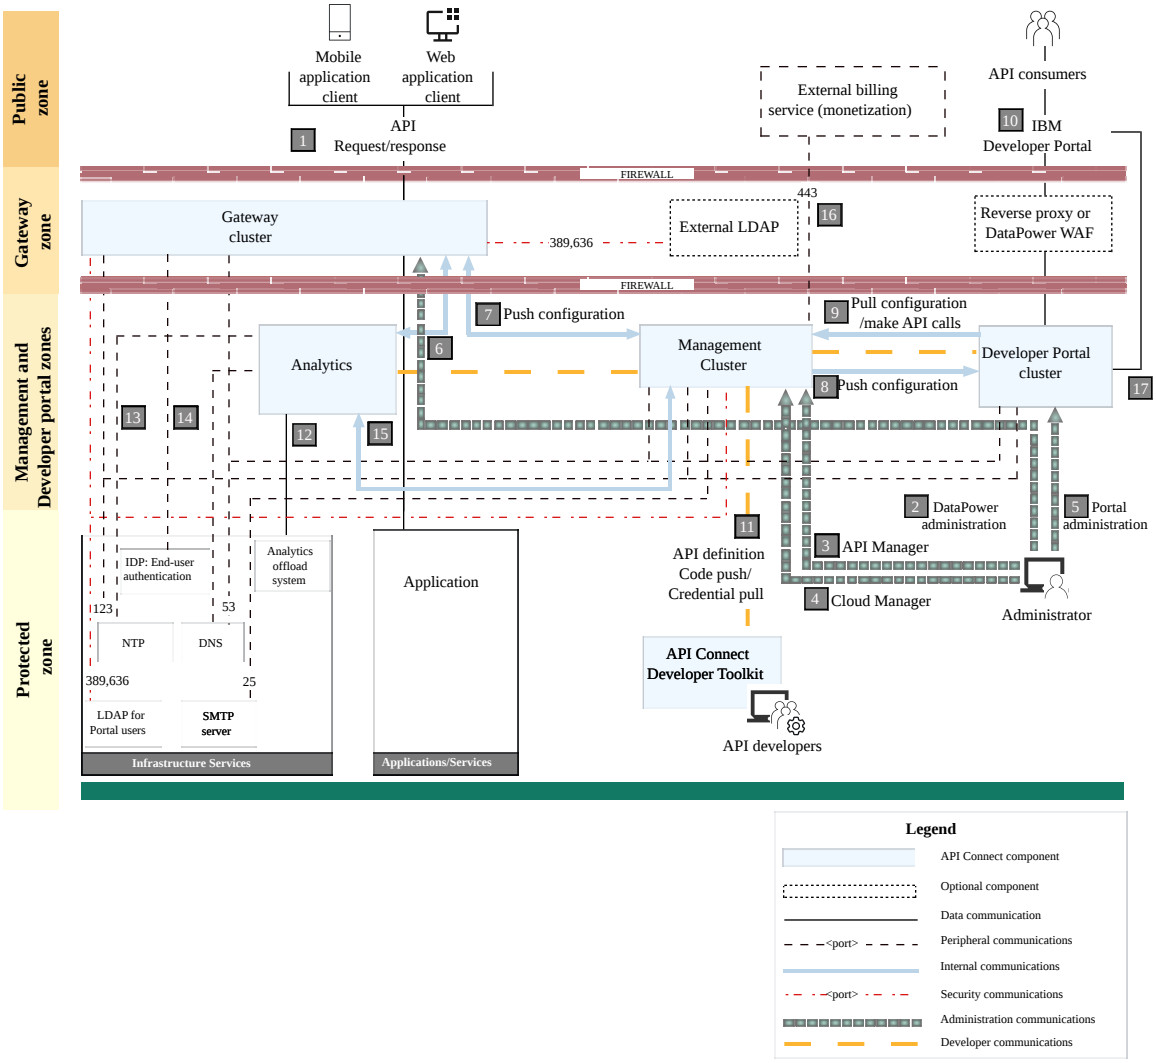


Table 1. Key for the network diagram example.
The following table lists the port numbers with a usage description.

	Usage description	Default port number
1	API request/response – Users invoking the provided APIs.	443 HTTPS from Public zone to Gateway zone
2	DataPower® administration – Internal operators who are managing the Gateway servers.	22 SSH, 9090 HTTPS from Protected zone to Gateway zone
3	API Manager – Internal business users who are defining and monitoring APIs.	443 HTTPS from Protected zone to Management zone
4	Cloud Manager – Internal operators who are administering the Cloud.	22 SSH, 443 HTTPS from Protected zone to Management zone
5	Developer Portal administration – Internal operators who are managing the Portal servers.	22 SSH, 443 HTTPS from Protected zone to Management zone
6	Gateway servers post traffic to Analytics service.	443 HTTPS from Gateway servers to Analytics service
7	Push configuration – Management servers communicate bi-directionally with Gateway servers.	3000 and 443 HTTPS Management servers to and from Gateway servers for webhook delivery. Port 3000 is the default port for apic-gw-service, and this is the port Management uses to communicate with Gateway. Port 443 is the default port for the platform-api endpoint, which apic-gw-service uses to communicate with Management.
8	Push configuration/webhooks – Management servers push configuration and webhooks to the Developer Portal.	443 HTTPS Management servers to Developer Portal servers for webhook delivery
9	Pull configuration/make API calls – Developer Portal servers pull configuration and call REST APIs.	443 HTTPS from Developer Portal servers to Management servers within Management zone
10	Developer Portal – External developers who are accessing the Developer Portal.	443 HTTPS from Public zone to Developer Portal management zone. The reverse proxy/DataPower WAF for incoming web traffic to the Developer Portal cluster must be a transparent proxy - no modification of the portal URL, port, host name or path is allowed.
11	Push API definition to Management server. Pick up credential for microservice code push.	443 HTTPS from Protected zone to Management zone

	Usage description	Default port number
12	Analytics offload	Port will depend on type of plugin and protocol used for the offload. Some possible protocols are: HTTP, HTTPS, TCP, UDP, KAFKA
13	Analytics accesses NTP	Standard NTP
14	Analytics access DNS	Standard DNS
15	Management service queries Analytics service	443 HTTPS within Management zone
16	External billing service – Management cluster connecting to external billing service (when configured for billing). If you are using Stripe as your external billing service, you must enable connections with the Stripe API at: https://stripe.com/files/ips/ips_api.json. You can also view the Stripe IP addresses at the following URL: https://stripe.com/docs/ips.	443 HTTPS from Management zone to Public zone
17	Developer Portal cluster must be able to access its own site endpoints.	443 HTTPS from Portal zone to Public zone

Firewall port requirements

The following tables lists ports that must be open in both cluster and non-clustered deployments.

Table 2. Firewall port requirements common to all subsystems

Subsystem	Ports and description
Ports that must be open on all API Connect subsystems	The following ports must be open on the Management Server, Analytics, and Developer Portal subsystems, whether in a cluster or not. • 22 (outbound) Used for SFTP backups on Management and Portal subsystems • 53 (outbound) DNS • 123 (outbound) NTP • 443 (inbound and outbound) Used by all subsystems for communication with other subsystems

Each subsystem uses ports in addition to the ports in Table 2. See the following table.

Table 3. Additional firewall port requirements for each subsystem

Subsystem	Ports and description
Management Service	Management Service uses the ports in Table 2 plus: • 22 remote backup server port (configurable) If backups are configured to use another port, ensure that the port is open. • 161 (inbound) SNMP • LDAP server port (if using LDAP user registry), typically 389 (outbound) • 3007 (outbound) LDAP The Automated test behavior application must be able to invoke (outbound) any port that a test system might present an API on. It can be bound to a particular port (if it is the same in all environments) or to a range of ports (to cover all of the ports it might invoke).
Developer Portal	The Developer Portal uses the ports listed in Table 2, plus: • 22 - A remote backup server port (configurable) If backups are configured to use another port, ensure that the port is open. See Configuring portal database backups.
Analytics	The Analytics subsystem uses the ports listed in Table 2. Analytics port usage considerations: • 161 for SNMP is required for both non-clustered and clustered deployments • In a non-clustered deployment, no additional ports are required. • Analytics supports an optional configuration for offload of data. This configuration might require additional outbound ports to be open.
Gateway Server	The Gateway Server uses these ports in both non-clustered and clustered deployments: • 161 (inbound and outbound) SNMP • 162 (outbound) SNMP traps • 3000 (inbound) Gateway Service local port (configurable) • 5550 (inbound) XML management port (configurable) • 5554 (inbound) REST management port (if enabled; configurable) • 9022 (inbound) Gateway SSH (if enabled; configurable) • 9090 (inbound) Web GUI console (if enabled; configurable) • 9443 (inbound) Gateway local port (configurable)

Communications inside the Gateway cluster

There are a number of important points to note regarding the communications within the Gateway cluster.

- We advise that you use the same port for all Gateway servers within a cluster.
- Gateway servers communicate with each other to synchronize invocation counts.
- All Gateway servers in a Gateway cluster must be able to reach all of the other Gateway servers in the same Gateway cluster.
- Gateway servers in a Gateway cluster do not directly communicate with Gateway servers in a different Gateway cluster.
- All Gateway servers must be able to reach the management subsystem platform API endpoint, which was configured during the installation of your API Connect environment.

Ethernet interface usage

To separate network traffic, you can use two or more Ethernet interfaces on the DataPower appliance on which a Gateway server is installed. For example, you can use one interface for internal IBM API Connect communications, and another for processing incoming API calls.

Port requirement for Stripe billing service

All Management servers and Developer Portal servers must be able to communicate HTTPS content with the external billing service when billing is configured. If you are using Stripe as your external billing service, you must enable HTTPS communication on port 443 with the Stripe API: https://stripe.com/files/ips/ips_api.json.
Note: API Connect does not support using webhooks with Stripe. You can see a list of the Stripe IP addresses at: https://stripe.com/docs/ips.

Planning your analytics deployment

Plan your API Connect analytics deployment by reviewing options for deployment profile and estimating required persistent storage space.

Deployment profile

Decide which deployment `profile` you want to use, the available profiles are:

- For Kubernetes and OpenShift (individual subsystem) installations: Analytics deployment profiles.
- For Cloud Pak for Integration and OpenShift top-level CR installations: API Connect deployment profiles.

For a scalable analytics deployment, choose a three replica profile. If you do not expect a high API transaction rate and plan to keep a limited amount of analytics data, then a one replica profile is sufficient.

Storage class

Before you install analytics, you must choose a storage class. **`Ceph`**, **`Block`**, and **`Local Volume`** are all supported; however, **`Local Volume`** is the most suitable for analytics. The analytics subsystem provides internal data replication and HA support, so the additional HA capabilities that **`Ceph`** or **`Block`** storage might give you are not needed. In addition, analytics requires a high throughput of disk I/O operations to successfully handle the analytics data load from the gateway. **`Local Volume`** is the best-performing storage class for disk I/O.

Note: GlusterFS, NFS, Rook-CephFS, or any shared file system storage class is not supported for analytics. If you use these storage classes, you might encounter severe performance degradation, pod crashloops, and possibly loss of data.

Storage type

Note: Storage type selection is available on three replica deployments only.
To make an informed choice on which storage type is best for you, first read and understand the OpenSearch concepts that are described in OpenSearch nodes, indices, shards, and replicas.
API Connect provides two OpenSearch storage types:

- **Shared storage**
  A single pod provides data storage and OpenSearch cluster management. Shared storage is the only option on a one replica deployment.
- **Dedicated storage**
  OpenSearch data storage and cluster management functions are split, and run in separate pods on each worker node:
  - The **`storage-os-master`** pod runs an OpenSearch "manager eligible" node that manages the OpenSearch cluster, but does not store any API event data.
  - The **`storage`** pod runs an OpenSearch "data" node that stores API event data.

  Dedicated storage is the default storage type for three replica deployments.

Dedicated storage facilitates horizontal scaling to support greater analytics data storage and throughput. Add worker nodes and increase the number of **`storage`** pod replicas to scale horizontally (you do not need to increase the number of **`storage-os-master`** replicas). Dedicated storage also provides greater stability and allows some OpenSearch configuration changes to be made without downtime.
You can change storage type after installation, see Dedicated storage and scaling up.

Disabling internal storage

The analytics subsystem provides a complete solution for routing, storing, and viewing the analytics data. However, you might not need the internal storage and viewing solution if you are using a third-party system for data offloading. In this scenario, you can greatly reduce your CPU and memory costs by disabling the internal storage and viewing components.

When you disable internal storage for analytics data, the following microservices are disabled:

- **`osinit`**
- **`storage`**

Important:
If you disable local storage, the analytics views in your API Connect UIs remain accessible, but are empty.

Configure local storage disablement before installation. It is not possible to disable or re-enable internal storage after installation.

You can enable offload of analytics data to third-party systems after installation.

For the steps to disable internal storage, see Disable local storage.

Persistent storage space

Based on your expected API transaction rate, you can estimate how much storage space your analytics subsystem requires. See Estimating storage requirements.

Inter-subsystem communication security

By default the network communication from the management and gateway subsystems, to the analytics subsystem uses Kubernetes ingresses or OpenShift routes, and is secured with mTLS. You can configure alternative network communication options if your environment requires. For more information, see Network requirements for inter-subsystem communication.

Kubernetes operating map counts

When the analytics service is configured to store data, it uses OpenSearch, which requires map counts higher than the operating system defaults. The minimum recommended value is `262144`. Unless you plan to disable local storage, increase the default map count on every Kubernetes worker node:

1. To change the map counts on the live system, run the following command on every Kubernetes node:

   ```
   sudo sysctl -w vm.max_map_count=262144
   ```

2. To persist this change when node restarts occur, add the following setting to the /etc/sysctl.conf file:

   ```
   vm.max_map_count = 262144
   ```

For more information, see Important settings in the OpenSearch documentation.

PV requirements

The number of PVs needed depends on if you disable local storage, and if you have backups configured.

Table 1. Analytics PV requirements

Deployment profile	Local storage disabled (ingestion only)	Local storage enabled	Local storage and backups enabled
Single node (n1)	1	2	3
Three node (n3)	3	6	9

To understand how much storage capacity your analytics subsystem needs, see Estimating storage requirements.

Firewall requirements

The analytics firewall requirements are documented here: Firewall requirements

Key Concepts: Cert-manager, Issuers, and Secrets

By default API Connect uses an open source product that is called cert-manager to handle the issuing and renewal of the certificates that are used by API Connect. The cert-manager has its own Kubernetes pods and runs in its own namespace. The cert-manager adds some additional resources to the Kubernetes environment. The API Connect administrator needs to be familiar with these additional resources:

Issuers

Issuers play the part of certificate authorities (CAs) in the local environment and issue the certificates. Issuers reside in the API Connect namespace. There are two types of Issuers:

- Self-Signed - This issuer provides the self-signed certificates, for example a root CA.
- CA - This issuer can be either the root certificate authority or an intermediate certificate authority.

Here is an example of the issuers that can be found on the management subsystem:

```
kubectl get issuers -n <management namespace>
NAME                  READY   AGE
abc-management-ca     True    96d
selfsigning-issuer    True    96d
```

- `selfsigning-issuer` This is a SelfSigned Issuer that provides the root certificate for all default certificates that are used in API Connect.
- `abc-management-ca` This is a CA Issuer that signs all the end-entity certificates that are used for communication between the management subsystem pods. It is in effect an intermediate CA between the root (`selfsigning-issuer`) and the end-entity certificates.

Certificates

A certificate is a Kubernetes resource that contains a pointer to a Kubernetes secret. The Kubernetes secret contains the actual TLS certificate. Certificate objects contain other information such as the issuer, expiry date, and status. Run `kubectl get certificate` to see the certificates on an API Connect subsystem:

```
kubectl get certificate -n <management namespace>
NAME                                    READY   SECRET                                  AGE
abc-management-ca                       True    abc-management-ca                       96d
abc-management-client                   True    abc-management-client                   96d
abc-management-natscluster-mgmt         True    abc-management-natscluster-mgmt         96d
abc-management-server                   True    abc-management-server                   96d
...
```

The first certificate in the list `abc-management-ca` is the intermediate CA certificate that is used for signing the other certificates that are shown in the output. If you describe this certificate you can see that the `selfsigning-issuer` is its issuer:

```
kubectl describe certificate abc-management-ca -n <management namespace>
...
Spec:
  ...
  Issuer Ref:
    Kind:  Issuer
    Name:  selfsigning-issuer
```

Describing the other management subsystem certificates, observe that the `abc-management-ca` certificate is the issuer:

```
kubectl describe certificates abc-management-client -n <management namespace>
...
Spec:
  ...
  Issuer Ref:
    Kind:  Issuer
    Name:  abc-management-ca
```

Key points:

- The certificates with '-ca' on the end are all CA Certificates, and they sign all the other subsystem certificates whose names do not end with '-ca'.
- The CA certificates are also known as Issuer certificates.
- Certificates that CA certificates sign are known as end-entity certificates.
- When a CA certificate is updated, all end-entity certificates that it signs must also be updated.

For a complete list of the certificates in an API Connect installation, see API Connect certificates reference.

Secrets

Secrets are the Kubernetes resource for storing credentials. In API Connect, secrets are where the TLS certificates are stored. Every Kubernetes certificate object has a corresponding secret of the same name. The Kubernetes certificate contains a property that refers to its corresponding secret:

```
kubectl describe certificates abc-management-client -n <management namespace>
...
Spec:
  ...
  Secret Name:        abc-management-client
```

The default output of `kubectl get certificate` includes a column that is labeled `SECRET`, which shows the secret name.

```
kubectl get certificate -n <management namespace>
NAME                                    READY   SECRET                                  AGE
abc-management-ca                       True    abc-management-ca                       96d
abc-management-client                   True    abc-management-client                   96d
abc-management-natscluster-mgmt         True    abc-management-natscluster-mgmt         96d
abc-management-server                   True    abc-management-server                   96d
...
```

The `kubectl describe` output of a secret shows that it contains the TLS certificates:

```
kubectl describe secret abc-management-client -n <management namespace>
...
Name:         abc-management-client
Namespace:    default
Labels:       app.kubernetes.io/instance=abc-management
              app.kubernetes.io/managed-by=ibm-apiconnect
              app.kubernetes.io/name=abc-management-client
Annotations:  cert-manager.io/alt-names:
              cert-manager.io/certificate-name: abc-management-client
              cert-manager.io/common-name: abc-management-client
              cert-manager.io/ip-sans:
              cert-manager.io/issuer-group:
              cert-manager.io/issuer-kind: Issuer
              cert-manager.io/issuer-name: abc-management-ca
              cert-manager.io/uri-sans:

Type:  kubernetes.io/tls

Data
====
ca.crt:   1107 bytes
tls.crt:  1139 bytes
tls.key:  1675 bytes
```

The full TLS certificate strings can be seen with:

```
kubectl get -o yaml secret <secret name> -n <namespace>
```

For more details about cert-manager, and a full list of all the certificates that are created and used in an API Connect deployment, see API Connect certificate reference.

Webhooks deployed and managed by the API Connect Operator

The API Connect Operator deploys and manages various Kubernetes API webhooks in the cluster to assist in management of its custom resources.

The webhooks included admission controllers and conversion webhooks.

Defaulting webhook

- Purpose
  The defaulting webhook is a type of Mutating Admission Webhook which runs against Custom Resources (CRs) at **CREATE** or **UPDATE** time to populate default values in the CR's **spec**.

- Creation
  Currently the defaulting webhook runtime is part of the API Connect Operator runtime, that is it exists within the API Connect Operator pod and container. When the operator boots, it creates **MutatingWebhookConfiguration** resources for each CRD (listed below). This **MutatingWebhookConfiguration** is a cluster-scope resource, but the configuration within will be specific to the namespace and operator instance which created it. If more than one instance of the API Connect Operator is deployed across a cluster (in different namespaces) there will be a set of webhook configurations for each API Connect Operator instance and namespace.

  The name for the **MutatingWebhookConfiguration** resource for each CRD will take the following form:

  ```
  <namespace>.<crd-name>.defaulter[.<component>].apiconnect.ibm.com
  ```

  The following CustomResourceDefinitions utilize a defaulting webhook:

  ```
  AnalyticsCluster
  ApiconnectCluster
  GatewayCluster
  ManagementCluster
  ManagementDBUpgrade
  ManagementRestore
  PortalCluster
  ```

- Lifecycle
  While the defaulting webhook runtime itself lives within the API Connect Operator pod, the **MutatingWebhookConfiguration** is a cluster-scope resource and is stand-alone. When it is created, an **ownerReference** is set on it that references the API Connect Operator's **ClusterRole**. Thus, the lifecycle of the **MutatingWebhookConfiguration** resources will be linked with the **ClusterRole**, which is linked with the installation of the operator itself.

  When the operator is uninstalled, the **MutatingWebhookConfiguration** resources for that operator instance are also removed.

- Example
  The below output shows the defaulting webhook configurations created for an operator deployed in the **apiconnect-operator** namespace. One can be seen for each CRD.

  ```
  $ oc get mutatingwebhookconfiguration
  NAME                                                                WEBHOOKS   AGE
  apiconnect-operator.analyticsclusters.defaulter.analytics.apiconnect.ibm.com       1          4d4h
  apiconnect-operator.apiconnectclusters.defaulter.apiconnect.ibm.com                1          4d4h
  apiconnect-operator.gatewayclusters.defaulter.gateway.apiconnect.ibm.com           1          4d4h
  apiconnect-operator.managementclusters.defaulter.management.apiconnect.ibm.com    1          4d4h
  apiconnect-operator.managementdbupgrades.defaulter.management.apiconnect.ibm.com  1          4d4h
  apiconnect-operator.managementrestores.defaulter.management.apiconnect.ibm.com    1          4d4h
  apiconnect-operator.portalclusters.defaulter.portal.apiconnect.ibm.com             1          4d4h
  ```

Validating webhook

- Purpose
  The validating webhook is a type of ValidatingAdmissionWebhook which runs against Custom Resources (CRs) at **CREATE** or **UPDATE** time to validate the CR contains a configuration which will yield an operable cluster. The CustomResourceDefinitions use OpenAPI schema validation for basic property checks (such as integer bounds and non-empty strings), but more complex validation of the configuration is done via the webhook.

- Creation
  Currently the validating webhook runtime is part of the API Connect Operator runtime, i.e. it exists within the API Connect Operator pod and container. When the operator boots, it creates **ValidatingWebhookConfiguration** resources for each CRD (listed below). This **ValidatingWebhookConfiguration** is a cluster-scope resource, but the configuration within will be specific to the namespace and operator instance which created it. If more than one instance of the API Connect Operator is deployed across a cluster (in different namespaces) there will be a set of webhook configurations for each API Connect Operator instance and namespace.

  The name for the **ValidatingWebhookConfiguration** resource for each CRD will take the following form:

  ```
  <namespace>.<crd-name>.validator[.<component>].apiconnect.ibm.com
  ```

  The following CustomResourceDefinitions utilize a validating webhook:

  ```
  AnalyticsCluster
  ApiconnectCluster
  GatewayCluster
  ManagementCluster
  ManagementDBUpgrade
  ManagementRestore
  PortalCluster
  ```

- Lifecycle

While the validating webhook runtime itself lives within the API Connect Operator pod, the **ValidatingWebhookConfiguration** is a cluster-scope resource and is stand-alone. When it is created, an **ownerReference** is set on it that references the API Connect Operator's **ClusterRole**. Thus, the lifecycle of the **ValidatingWebhookConfiguration** resources will be linked with the **ClusterRole**, which is linked with the installation of the operator itself.

When the operator is uninstalled, the **ValidatingWebhookConfiguration** resources for that operator instance are also removed.

- Example
  The below output shows the validating webhook configurations created for an operator deployed in the **apiconnect-operator** namespace. One can be seen for each CRD.

```
validatingwebhookconfiguration
NAME                                                                      WEBHOOKS   AGE
apiconnect-operator.analyticsclusters.validator.analytics.apiconnect.ibm.com       1          4d4h
apiconnect-operator.apiconnectclusters.validator.apiconnect.ibm.com                1          4d4h
apiconnect-operator.gatewayclusters.validator.gateway.apiconnect.ibm.com           1          4d4h
apiconnect-operator.managementclusters.validator.management.apiconnect.ibm.com    1          4d4h
apiconnect-operator.managementdbupgrades.validator.management.apiconnect.ibm.com  1          4d4h
apiconnect-operator.managementrestores.validator.management.apiconnect.ibm.com    1          4d4h
apiconnect-operator.portalclusters.validator.portal.apiconnect.ibm.com             1          4d4h
```

Administering API Connect in your container environment

How to manage your API Connect subsystems in Kubernetes and OpenShift environments.

On all container platforms, your API Connect subsystems can be entirely managed from the command line, by using the Kubernetes **kubectl** command. On OpenShift, you can use the equivalent **oc** command instead of **kubectl**. However, since the **kubectl** command is recognized in OpenShift, the **kubectl** command is used in most example commands throughout this documentation.

On OpenShift, some administration operations can be done through the OpenShift console, and on Cloud Pak for Integration also through the Platform UI.

- **Namespaces in your container environment**
  How to administer API Connect in a namespace-scoped container environment.
- **Custom Resources and Custom Resource Definitions**
  Information about the Custom Resources (CRs) that make up API Connect.
- **Managing your API Connect CRs**
  How to update the API Connect CRs in your deployment.

Namespaces in your container environment

How to administer API Connect in a namespace-scoped container environment.

Namespaces are used in Kubernetes to allow separate groups of resources to run in the same Kubernetes cluster without interfering with each other. For example, you can have two Kubernetes pods with an identical name if they are in different namespaces.

When you install API Connect, you can use an existing namespace or create a new namespace for your API Connect installation to run in.

Cluster-scoped resources are Kubernetes resources that operate across multiple namespaces. The API Connect operator is installed at cluster-scope, and can manage multiple API Connect installations that are installed in different namespaces.

Whenever you run the **kubectl** command, you must specify which namespace the command is to run in. For example:

```
kubectl -n <namespace> get pods
```

where `-n <namespace>` defines the namespace to run the command in. If you specify the wrong namespace, the **kubectl** command fails:

```
kubectl -n wrong-ns get pod mypod
Error from server (NotFound): namespaces "wrong-ns" not found
```

Kubernetes and OpenShift have a default namespace that is used if no namespace is specified in **kubectl** commands. It is not recommended to install API Connect in the default namespace. Always create a dedicated namespace for each API Connect installation.

Throughout this document, **kubectl** commands are provided to run the various installation and maintenance operations that are used to manage your API Connect installation. For brevity, the `-n <namespace>` is not included in the example commands where the namespace to specify is clear from the context.

If you need to run a sequence of `kubectl` commands in the same namespace, you can set the default namespace so that you do not need to include `-n <namespace>` in the commands. To set the default namespace, run the following command:

- Kubernetes:

  ```
  kubectl config set-context --current --namespace=<namespace>
  ```

- OpenShift:

  ```
  oc project <namespace>
  ```

Custom Resources and Custom Resource Definitions

Information about the Custom Resources (CRs) that make up API Connect.

Custom Resources (CRs) are sets of Kubernetes resources (such as pods) that you can interact with using the **kubectl** command. An API Connect installation has a distinct CR for each API Connect subsystem: management, portal, gateway, and analytics.

Custom Resource Definitions (CRDs) are the Kubernetes resource that is used to define CRs. API Connect has a CRD for each subsystem:

- ManagementCluster
- PortalCluster
- GatewayCluster
- AnalyticsCluster

API Connect on Cloud Pak for Integration or on OpenShift with the top-level CR, has an extra CRD for the top-level CR:

- APIConnectCluster

Each API Connect subsystem CR defines the system-level properties for its subsystem such as endpoints, secrets, backup settings, and storage allocations. The properties are defined in YAML format. The syntax to view the properties of an API Connect CR are:

```
kubectl -n <namespace> get <API Connect CRD name> <API Connect CR name> -o yaml
```

Example output:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  annotations:
    ...
  creationTimestamp: "2023-12-06T17:37:28Z"
    ...
  name: management
  namespace: apic
  ...
  uid: 9e67df02-d044-4a5b-8fb5-93391722ae97
spec:
  adminUser:
    secretName: management-admin-pass
  ...
  analytics:
    client: {}
    ingestion:
      secretName: management-a7s-ing-client
  apiManagerEndpoint:
    annotations:
      cert-manager.io/issuer: management-ingress-issuer
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: management-api-manager-apic.apps.ibm.com
      secretName: management-api-manager
    ...
  databaseBackup:
    ...
  databaseVolumeClaimTemplate:
    storageClassName: rook-ceph-block
    ...
  version: 10.0.x.y
  ...
status:
  conditions:
  - lastTransitionTime: "2023-12-06T17:47:47Z"
    message: All services ready
    reason: na
    status: "True"
    type: Ready
...
```

To refer to a specific property in the CR, dot notation is used, so the property:

```
metadata:
  annotations:
```

is referred to as `metadata.annotations`. In the example output shown previously, some properties of interest are highlighted in bold:

- `kind: ManagementCluster`. The `kind` property refers to the CRD that defines the CR.
- `name: management`. The name of the CR itself. When you want to run a kubectl operation on the CR, you specify the CR name in the command.
- `namespace: apic`. The name of the namespace the CR exists in.
- `spec:` The `spec` section contains the properties of your API Connect subsystem, such as URLs for the endpoints and scheduled database backup settings.
- `spec.apiManagerEndpoint.hosts.name` is where you define the URL of the API Manager UI.
- `status:` The `status` section shows information about the current state of the subsystem, including any errors or warnings.

You can have multiple portal, analytics, and gateway CRs in the same namespace, each registered with the management subsystem as separate services. You cannot have multiple management CRs in the same namespace. To list all the installed CRs for a portal, analytics, or gateway CRD, run:

```
kubectl get <CRD name>
```

where *<CRD name>* is `PortalCluster`, `GatewayCluster`, or `AnalyticsCluster`. Example output:

```
kubectl get PortalCluster
```

```
NAME        READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                                AGE
ptl_1       3/3     Running   10.0.x.y   10.0.x.y-3968        Ready for API Cloud Manager service registration   6d22h
ptl_2       3/3     Running   10.0.x.y   10.0.x.y-3968        Ready for API Cloud Manager service registration   9d12h
```

The output shows two portal CRs. To get just information on one of the CRs, specify that CR name in the **kubectl get** command:

```
kubectl get PortalCluster ptl_2

NAME        READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                                  AGE
ptl_2       3/3     Running   10.0.x.y   10.0.x.y-3968        Ready for API Cloud Manager service registration   9d12h
```

Tip: Instead of typing the full CRD names `ManagementCluster`, `PortalCluster`, `GatewayCluster`, or `AnalyticsCluster`, you can use the following shorter alternatives:

- `mgmt` for `ManagementCluster`
- `ptl` for `PortalCluster`
- `gw` for `GatewayCluster`
- `a7s` for `AnalyticsCluster`

To see all the API Connect CRs in a namespace, use the `kubectl get apic` command:

```
kubectl get apic -n <namespace>
NAME
                                                  READY   STATUS    VERSION    RECONCILED VERSION   AGE
analyticscluster.analytics.apiconnect.ibm.com/test-a7s   n/n     Running   10.0.x.y   10.0.x.y-2248        5d

NAME                                                READY   STATUS    VERSION    RECONCILED VERSION   AGE
gatewaycluster.gateway.apiconnect.ibm.com/test-gw   n/n     Running   10.0.x.y   10.0.x.y-2248        5d

NAME                                                   READY   STATUS    VERSION    RECONCILED VERSION   AGE
managementcluster.management.apiconnect.ibm.com/test-mgmt   n/n   Running   10.0.x.y   10.0.x.y-2248        5d1h

NAME                                               READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
AGE
portalcluster.portal.apiconnect.ibm.com/test-ptl   n/n     Running   10.0.x.y   10.0.x.y-2248        Ready to create sites   5d
```

Managing your API Connect CRs

How to update the API Connect CRs in your deployment.

Updating an API Connect CR requires editing the CR and adding, updating, or deleting individual properties or entire sections of the CR. Two methods exist to edit a CR:

- Edit the CR manually with the **kubectl** edit command. The **kubectl** edit command opens the CR in an editor, where standard **vi** operations can be used to update the CR:

  ```
  kubectl edit ptl <portal cr name>
  ```

  Make the changes that you want in the CR, for example update the value of `spec.databaseBackup.schedule`, then save and exit.
  Note: You can omit the CR name in the edit command. To open all portal CRs in the namespace for editing, run:

  ```
  kubectl edit ptl
  ```

  For brevity, the CR name is often omitted where **kubectl** edit commands are provided in this documentation.

- Use the **kubectl** `patch` operation to update the CR in a single command, for example:

  ```
  kubectl patch managementcluster <mgmt cr name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
  ```

  In this example, the patch operation removes the entire `spec.multiSiteHA` section from the management CR.

  Patch operations that require updating multiple properties in the same CR can be done by creating a YAML file that contains all the properties to change, for example:

  ```
  kubectl patch mgmt <mgmt cr name> --type merge --patch "$(cat <YAML file>)"
  ```

  where *<YAML file>* is the file that contains the properties to update.
  Note: With `patch` operations, you must always specify the CR name, even if you have only one CR of the CRD type in the namespace.

Both methods for updating CRs are used throughout this documentation.

Installing API Connect

Use these instructions to install a deployment of API Connect on Kubernetes, OpenShift, and IBM Cloud Pak for Integration.

To deploy API Connect, complete the tasks in the sequence below.

- **Deployment requirements**
  Describes the system requirements for deploying into the Kubernetes, OpenShift, and Cloud Pak for Integration runtime environments.
- **Deployment procedures**
  You can use these procedures to deploy API Connect on either native Kubernetes or OpenShift.

Deployment requirements

Describes the system requirements for deploying into the Kubernetes, OpenShift, and Cloud Pak for Integration runtime environments.

Before you begin

Note: This article refers to third-party software that IBM does not control. As such, the software might change and this information might become outdated. Kubernetes is a platform for automated deployment, scaling, and operation of application containers across clusters of hosts, providing container-centric infrastructure. For more information, see https://kubernetes.io.

These instructions assume you have a working Kubernetes environment and understand how to manage Kubernetes.

About this task

Review all the requirements listed in the following steps before starting your API Connect deployment.

Note: If you plan to install the Automated API behavior testing application, review the *Before you begin* section in Installing the Automated API behavior testing application because the requirements might have an impact on your deployment choices for API Connect.

Procedure

1. Verify that you have supported software.
   - Refer to the IBM Software Product Compatibility Reports site for detailed requirements for operating systems, supporting software, and other prerequisites. See Detailed system requirements for a specific product
   - For new installations, the API Connect operators and operands must be at compatible versions. This requirement applies to native Kubernetes and OpenShift installations.
     - Note that the API Connect operator version *number* does not match the API Connect release version *number*. You can view a mapping of API Connect release number to API Connect operator version numbers in Deploying operators and cert-manager.
     - For API Connect operands (Management, Portal, Analytics, and Gateway subsystems), the version number matches the API Connect release version number.

2. Verify that your Kubernetes environment is running and meets the configuration requirements for API Connect:
   - When using IBM Cloud Kubernetes Service, ingress-nginx is required.
   - Specify settings for the ingress controller for a Kubernetes runtime environment. See Kubernetes ingress controller prerequisites.
   - The timezone for API Connect pods is set to UTC. Do not change the timezone for the pods.
   - To ensure the API Connect services have time to start, we recommend increasing the *proxy-read-timeout* and *proxy-send-timeout* values in the *config.map* used to configure the kubernetes/ingress-nginx ingress controller. The following settings should be increased:
     - proxy-read-timeout: "240"
     - proxy-send-timeout: "240"

     240 seconds (4 minutes) is a recommended minimum; actual value will vary depending upon your environment. If there is a load balancer in front of the worker node(s), then the load balancer configuration may also need to have extended timeouts.
   - Storage type:
     When selecting storage type, review the following considerations:

     - Management subsystem requires block storage.
     - Developer Portal subsystem supports block storage or local volume storage.
     - Analytics subsystem supports block storage or local volume storage.

     Supported storage types
     - Block storage
       Select a block storage format of your choosing in order for API Connect components to be supported. Supported block storage types include, but are not limited to:

       - Rook Ceph
         Note: cephrbd (RADOS Block Device) is recommended over cephfs file system

       - OpenShift Container Storage
       - Portworx
       - IBM Cloud Block Storage
       - AWS: the gp2, gp3, io1, and io2 types of Elastic Block Storage (EBS) are supported.
       - Azure Premium Storage
       - GCE Persistent Disk

       See also the **API Connect v10.0.8.x WhitePaper** for information on limitations observed with other block storage solutions: https://community.ibm.com/community/user/integration/viewdocument/ibm-api-connect-v1008x-deploymen?CommunityKey=2106cca0-a9f9-45c6-9b28-01a28f4ce947&tab=librarydocuments

     - Local volume storage

       Management subsystem and Developer Portal subsystem
       Local volume storage is not recommended for the Management subsystem and Developer Portal subsystem because it has severe performance impacts for high availability deployments, and for pod allocation.
       Note also that local volume storage is not available in most cloud environments, and might incur limitations in disaster recovery scenarios, since it is tied to the node on which the pod is run. This means that use of LVS might be adequate for deployments with a one replicaprofile, but inadequate for deployments with a three replica profile.

       Analytics subsystem
       For Analytics subsystems, transactions per second (TPS) is three times faster with local volume storage than with Ceph block storage. In a production scenario, you will have multiple analytics-storage (OpenSearch) nodes forming a storage cluster. OpenSearch will manage data replication across its cluster and ensure high availability, thus mitigating possible local volume storage drawbacks with disaster recovery.

     Non-supported storage
     - NFS
       API Connect v10 cannot be deployed on NFS.

- GlusterFS
  GlusterFS is not recommended as a storage option due to severe performance degradation and in some cases, loss of data. There are known GlusterFS issues that affect OpenSearch (which is used in the API Connect analytics service), the Developer Portal and the Management subsystem
- IBM Spectrum Scale
  This storage class does not support block storage.

- Storage class configuration:
  In your Kubernetes cluster configuration, you must create storage classes with the setting:

  ```
  volumeBindingMode: WaitForFirstConsumer
  ```

  This setting is needed to avoid volume node **affinity** conflicts, such as those caused by **requiredPodAntiAffinity** restrictions. If **WaitForFirstConsumer** is the binding mode, PVCs (PersistentVolumeClaims) are only bound once the pod is actually created.

  By contrast, when the binding mode is immediate (**volumeBindingMode: Immediate**), the PVCs are bound to PVs (PersistentVolumes) as soon as the PV is created.

  Example: When deploying to a multi-zone cluster, you must use StorageClass with **WaitForFirstConsumer** because when binding mode is immediate, successful deployment is indeterminate because of interactions between pod/node affinity and the Kubernetes provisioning of the PV on the right node where the pod is being provisioned.

  For more information, see "Volume Binding Mode" on https://kubernetes.io/docs/concepts/storage/storage-classes/.

  Note: During deployment, you are required to specify the name of the storage class you created. You can either use the setting **storageClassName: $STORAGE_CLASS** in the applicable CR (such as apiconnect top-level CR or an individual subsystem CR), or you can use a configuration UI such as Platform Navigator UI or OpenShift Container Platform (OCP) UI.
- When the Analytics service is configured to store data, (that is, it is not configured for ingestion-only), the service depends on OpenSearch, which requires map counts higher than the operating system defaults. See: Installing the analytics subsystem.
  If you are deploying on OpenShift, the map count is preconfigured (**vm.max_map_count = 1027580**) with a value that is sufficiently large for OpenSearch so you do not need to modify this setting.

- Ensure that your Kubernetes deployment addresses known security vulnerabilities with SSH to prevent the use of weak SSH Message Authentication Code (MAC) and Key exchange algorithms (KexAlgorithms) with TCP over port 22. Use of weak algorithms can allow an attacker to recover the plain text message from the encrypted text. If you have not yet addressed the security vulnerabilities with weak MACs and KexAlgorithms, update your configuration manually by adding the following lines to /etc/ssh/sshd_config:

  ```
  KexAlgorithms curve25519-sha256@libssh.org,diffie-hellman-group-exchange-sha256
  MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
  ```

- IBM API Connect requires a number of container registry repositories to be added to your container registry service if automatic repository creation is not supported. Follow the procedure in Step 4 of Obtaining product files.

- Logging:
  - Configure a remote server for logging. See Logging. Pods are terminated during an upgrade, and the logs will be lost if not stored remotely.
  - Configure the log rotation by setting the **max-size** and **max-files** values to a setting appropriate for your deployment. In a Kubernetes deployment, insufficient values for max-size and max-files can cause logs to grow too large and eventually force pods to restart.
    For more information, visit the Docker documentation and search for "JSON File logging driver".

3. Ensure your deployment meets the DNS requirements for API Connect domain names, host names, and endpoints.
   You specify endpoints when you edit the custom resource templates for each subsystem, and when you use the Cloud Manager UI to configure the services for your cloud. The domain names you use for the endpoints must be recognized by your DNS configuration. DNS entries must meet these requirements:

   Important: For API Connect on native Kubernetes and OpenShift, do not use coredns 1.8.1 through 1.8.3. These releases have a defect that can prevent pods for Developer Portal from starting. See https://coredns.io/.
   - Endpoints cannot contain the underscore character `"_"` or uppercase characters.
   - Host names that are used to create endpoints cannot contain the underscore character `"_"` or uppercase letters.
   - DNS must be configured with domain names that correspond to the endpoints configured at installation time for each subsystem.
   - Host names and DNS entries may not be changed on a cluster after the initial installation.
   - Kubernetes ingress limits the character set for DNS names to not support the underscore character `"_"`. This means you cannot specify underscores in domain names that are used as endpoints. For example, **my_domain.abc.com** and **my.domain_abc.com** are not supported for **<xxx>.<hostname>.<domainname>**, and will cause an error:

     ```
     Invalid value: "my_domain.abc.com": a DNS-1123 subdomain must consist of lowercase alphanumeric characters, '-' or '.',
     and must start and end with an alphanumeric character (e.g. 'example.com', regex used for validation is
      '[a-z0-9]([-a-z0-9]*[a-z0-9])?(\.[a-z0-9]([-a-z0-9]*[a-z0-9])?)*')
     ```

   - We recommend that you keep a record of the DNS entries and endpoint names, as you will need to map the DNS entries and use the same endpoints when restoring a backup of the management database. Note that endpoints are FQDNs, entered in all lowercase.
   - Specifying domain names when deploying CRs (custom resources) for each subsystem:
     The custom resource templates provide endpoint settings that consist of a default endpoint prefix and a variable **$STACK_HOST** that you set to specify your domain name, as part of Installing the API Connect subsystems.

   Table 1. Endpoints with domain names that must be configured in DNS

Default endpoint name	Description
admin.$STACK_HOST	Cloud Manager URL endpoint for the Management subsystem
manager.$STACK_HOST	API Manager URL endpoint for the Management subsystem
api.$STACK_HOST	Platform REST API Endpoint for admin and provider APIs
consumer.$STACK_HOST	Platform REST API Endpoint for consumer APIs for the Management subsystem.
rgw.$STACK_HOST	Gateway Endpoint for API invocation for DataPower API Gateway
rgwd.$STACK_HOST	Gateway Management Endpoint for DataPower API Gateway

Default endpoint name	Description
`gw.$STACK_HOST`	Gateway Endpoint for API invocation for DataPower Multi-Protocol Gateway (v5-compatible)
`gwd.$STACK_HOST`	Gateway Management Endpoint for DataPower Multi-Protocol Gateway (v5-compatible)
`ai.$STACK_HOST`	Analytics ingestion endpoint for the Analytics subsystem
`api.portal.$STACK_HOST`	Developer Portal admin endpoint
`portal.$STACK_HOST`	Developer Portal UI endpoint

- Specifying endpoints using the Cloud Manager interface
  After initial deployment of the Kubernetes custom resource for each subsystem, you will also enter the endpoints in the Cloud Manager user interface when defining each service as part of Defining your topology.

4. The Cloud Provider for the target Kubernetes platform must provide Ingress Controller support for SSL Passthrough.
   For example, if the Cloud Provider uses or suggests the use of the NGINX Community Ingress, then the **`--enable-ssl-passthrough`** flag would need to be provided at runtime, as described at https://kubernetes.github.io/ingress-nginx/user-guide/tls/#ssl-passthrough. For IBM Cloud Kubernetes Service, see https://cloud.ibm.com/docs/containers?topic=containers-ingress-user_managed..
5. If you plan to deploy API Connect on Kubernetes with DataPower Gateway in a *non-Kubernetes* environment, such as a DataPower appliance, review the API Connect requirements for operation with DataPower Gateway:
   - When deploying with a DataPower appliance, configure a Gateway Service Management Endpoint and API invocation Endpoint in DataPower. See *Configuring the API Connect Gateway Service* in the appropriate version of the DataPower documentation.
   - Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect Management server version.
     Note:
     Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.
6. If you plan to deploy the API Connect management subsystem and the DataPower Gateway subsystem on a Kubernetes deployment, managed by the DataPower and API Connect Operators, you can use any combination of API Connect 10.0.8.x with DataPower Gateway 10.6.0.y or DataPower API Gateway 10.6.0.y.
7. Observe namespace restrictions:
   - OpenShift
     Only one top level CR (APIConnectCluster) can be deployed in each namespace.
   - Cloud Pak for Integration
     In the Platform Navigator UI, only one APIConnect capability can be deployed in each namespace.
   - Native Kubernetes
     Only one instance of a subsystem can be deployed in each namespace. Deploying multiple similar subsystems in a single namespace is not supported. For example, there is no support for deploying two management subsystems, **`mgmt1`**, **`mgmt2`** in a single namespace where API Connect operator is installed.
8. The following kernel or Kubernetes node limits for the Developer Portal subsystem must be set correctly:
   - Ensure that your kernel or Kubernetes node has the value of its **`inotify`** watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a **`non-ready`** state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of **`inotify`** watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take **`inotify`** watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.
   - Ensure that your kernel or Kubernetes node has a value of **`nproc`** (maximum number of processes) that applies to the user ID of the portal pods that have been assigned, and that it is high enough to allow all of the portal processes to execute. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls, you might need as many as 125205. If the number is too low, you will see errors like **`"fork: retry: Resource temporarily unavailable"`** in the portal logs. Note that this value might need to be even higher if other, non-portal, pods are sharing the same user ID.
   - Ensure that your kernel or Kubernetes node has a value of **`nofiles`** (maximum number of open file descriptors) that applies to the user ID of the portal pods that have been assigned, and that it is high enough to allow the portal to open all of the files that it requires. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls and portal web sites, you might need as many as 1048576. If the number is too low, you will see errors like **`"too many open files"`** in the portal logs. Note that this value might need to be even higher if other, non-portal, pods are sharing the same user ID.
9. Your Kubernetes environment must have access to an S3 object-store, for remote storage of API Connect subsystem database backups.

- **IBM API Connect Version 10 software product compatibility requirements**
  Ensure that you install the minimum API Connect operating system requirements. Use the IBM Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.
- **API Connect licenses**
  When you install a new version of API Connect, you must accept a license for the API Connect program that you purchased.

IBM API Connect Version 10 software product compatibility requirements

Ensure that you install the minimum API Connect operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.

Generating a Software Product Compatibility Report

To generate an API Connect requirements report, complete the following steps:

1. Open the Detailed system requirements for a specific product page on the IBM Software Product Compatibility Reports site.
2. Search for the IBM API Connect product.
3. In the Search results list, select IBM API Connect.
4. From the Version list, select the required version.

5. Use the Filters to refine the contents of the requirements report.
6. Click Submit to generate your requirements report.

Supported versions of Kubernetes

Following table provides a quick reference of the supported Kubernetes versions for each API Connect release:

Table 1. API Connect and Kubernetes (K8S) compatibility matrix

API Connect version	K8S 1.24	K8S 1.25	K8S 1.26	K8S 1.27	K8S 1.28	K8S 1.29	K8S 1.30	K8S 1.31	K8S 1.32
10.0.5.4	✓	✓	✓	✓					
10.0.5.5			✓	✓	✓				
10.0.5.6				✓	✓	✓			
10.0.5.7				✓	✓	✓			
10.0.5.8					✓	✓	✓		
10.0.6.0	✓	✓	✓	✓					
10.0.7.0			✓	✓	✓				
10.0.8.0					✓	✓	✓		
10.0.8.1						✓	✓	✓	
10.0.8.2-ifix1							✓	✓	✓

To upgrade API Connect on Kubernetes, see Upgrading on Kubernetes.

Supported versions of Red Hat OpenShift Container Platform

Following table provides a quick reference of the supported OpenShift versions for API Connect:

Table 2. API Connect and OpenShift Container Platform (OCP) compatibility

API Connect version	OCP 4.10	OCP 4.12	OCP 4.14	OCP 4.15	OCP 4.16	OCP 4.17	OCP4.18
10.0.5.4	✓	✓					
10.0.5.5	✓	✓	✓				
10.0.5.6		✓	✓				
10.0.5.7		✓	✓				
10.0.5.8		✓	✓		✓		
10.0.6.0	✓	✓					
10.0.7.0		✓	✓				
10.0.8.0		✓	✓	✓	✓		
10.0.8.1		✓	✓	✓	✓	✓	
10.0.8.2-ifix1		✓	✓	✓	✓	✓	✓

To upgrade API Connect on OpenShift, see Upgrading on OpenShift and Cloud Pak for Integration.

API Connect licenses

When you install a new version of API Connect, you must accept a license for the API Connect program that you purchased.

When you install or upgrade API Connect, the procedures include instructions for specifying your license. Be sure to specify a license ID from the version of API Connect that you are installing or are upgrading to.

The licenses in Table 2 are used as the master mod-level license for all API Connect Fix Pack and security roll-up releases in this stream. There are no changes to license terms, only updates to open source notices documented in the notes for each.

Table 1. API Connect 10.0.8.1 and later licenses

License ID	Program Name	URL
L-HTFS-UAXYM3	IBM API Connect Enterprise V10.0.8.1+	https://ibm.biz/Bdan6M
L-FTGN-WUM5C5	IBM Cloud Pak for Integration - API Calls 16.1.0	https://ibm.biz/BdmPjg

Table 2. API Connect 10.0.8.0 licenses

License ID	Program Name	URL
L-DZZQ-MGVN8V	IBM API Connect Enterprise V10.0.8.0	https://ibm.biz/BdmPj8
L-FTGN-WUM5C5	IBM Cloud Pak for Integration - API Calls 16.1.0	https://ibm.biz/BdmPjg
L-EFSE-DEGF6Z	IBM API Connect Enterprise Add-on for IBM Products V10.0.8.0	https://ibm.biz/BdmPZB
L-QXKE-G3NZ57	IBM API Connect Professional V10.0.8.0	https://ibm.biz/BdmPZD

Deployment procedures

You can use these procedures to deploy API Connect on either native Kubernetes or OpenShift.

- **Obtaining product files**
  Obtain the product files, upload the images to a Docker registry, and decompress the operators and templates.
- **Deploying on Kubernetes**
  Use the procedures in this section to install API Connect on native Kubernetes distributions.

- **Deploying on OpenShift and Cloud Pak for Integration**
  You can install API Connect in an OpenShift environment or as the API Management capability in IBM Cloud Pak for Integration.

Obtaining product files

Obtain the product files, upload the images to a Docker registry, and decompress the operators and templates.

Before you begin

- Ensure you have supported hardware and software. See IBM API Connect Version 10 software product compatibility requirements.
- Complete the Deployment requirements
- Install and run Docker on the local machine being used for API Connect installation. Log in to your image registry.

About this task

From the IBM Fix Central site, download the Docker image-tool file of the API Connect subsystems. Next, you will upload the image-tool file to your Docker local registry. If necessary, you can populate a remote container registry with repositories. Then you can push the images from the local registry to the remote registry.

You will also download the Kubernetes operators, API Connect Custom Resource (CR) templates, and Certificate Manager, for use during deployment configuration.

Note: If you have API Connect installed and want to upgrade your release version, follow the upgrade instructions in Upgrading on Kubernetes.

Procedure

1. Obtain the API Connect files:
   a. Go to the What's New in the latest version information page.
   b. Locate the Note: *You can access the latest files from <URL link>*. Select the *<URL link>* to go directly to the Announce page on Fix Central, where you can download files for the *latest version* of API Connect.

   The following files are used for initial deployment on native Kubernetes:

   IBM API Connect *<version>* for Containers
   : Docker images for all API Connect subsystems

   IBM API Connect *<version>* Operator Release Files for Containers
   : Kubernetes operators and API Connect Custom Resource (CR) templates

   IBM API Connect *<version>* Toolkit for *<operating_system>*
   : Toolkit command line utility. Packaged standalone, or with API Designer:
     - IBM API Connect *<version>* Toolkit for *<operating_system>*
     - IBM API Connect *<version>* Toolkit Designer for *<operating_system>*

     Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See Installing the toolkit.

   IBM API Connect *<version>* Local Test Environment
   : Optional test environment. See Testing an API with the Local Test Environment

   IBM API Connect *<version>* Security Signature Bundle File
   : Signature files that you can use to verify the integrity of your downloads.

2. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
3. Load the image-tool image in your Docker local registry. The image is contained in the IBM API Connect *<version>* for Containers file. For example:

   ```
   docker load < apiconnect-image-tool-<version>.tar.gz
   ```

   Ensure that the registry has sufficient disk space for the files.

4. If your Docker registry requires repositories to be created before images can be pushed, create the repositories for each of the images listed by the image tool. (If your Docker registry does not require creation of repositories, skip this step and go to Step 5.)
   a. Run the following command to get a list of the images from image-tool:

   ```
   docker run --rm apiconnect-image-tool-<version> version  --images
   ```

   b. From the output of each entry of the form **<image-name>:<image-tag>**, use your Docker registry repository creation command to create a repository for **<image-name>**.
   For example in the case of AWS ECR the command would be for each **<image-name>**:

   ```
   aws ecr create-repository --repository-name <image-name>
   ```

5. Upload the image:
   - If you do not need to authenticate with the docker registry, use:

     ```
     docker run --rm apiconnect-image-tool-<version> upload <registry-url>
     ```

   - Otherwise, if your docker registry accepts authentication with username and password arguments, use:

     ```
     docker run --rm apiconnect-image-tool-<version> upload <registry-url> --username <username> --password <password>
     ```

     Tip: On AWS, where the password can be a long string, you can substitute *<password>* with

     ```
     `aws ecr get-login-password --region region`
     ```

   - Otherwise, such as with IBM Container Registry, if you need the image-tool to use your local Docker credentials, first authenticate with your Docker registry, then upload images with the command:

     ```
     docker run --rm -v ~/.docker:/root/.docker --user 0 apiconnect-image-tool-<version> upload <registry-url>
     ```

Note: The previous command does not work on macOS if Docker is configured to use the `osxkeychain` credential store. In this case, complete the following steps:

- Disable **Docker > Preferences... > Securely store Docker logins in the macOS keychain**.
- Inspect `~/.docker/config.json` to make sure that it does not contain `"credSstore": "osxkeychain"`, as some versions of Docker-for-mac may handle the setting correctly per https://github.com/docker/for-mac/issues/4192.
- Authenticate with the Docker registry you intend to upload to.
- Run the command:

```
docker run --rm -v ~/.docker:/root/.docker --user 0 apiconnect-image-tool-<version> upload <registry-url>
```

- Once the upload of images is successful you may enable **Docker > Preferences... > Securely store Docker logins in the macOS keychain**.

Docker authentication notes:

- Both HTTPS and HTTP are supported. Best practice for Docker registry security is to use HTTPS by utilizing standard Docker load tools, to ensure your images and platform are protected. However, when necessary you can use HTTP by specifying the `--tls-verify=false` flag.
- When using a Docker registry on `localhost`, you might encounter that the image-tool Docker container is on the Docker network and typically without access to `localhost`. You can workaround this issue by using the `--network host` argument to the Docker command. Note that `--network host` is a Docker argument, not an image-tool argument.
- Example of using `--network host` and `--tls-verify=false`:

```
$ docker run -d -p 5000:5000 --name registry registry:2
...
$ docker run --rm --network host apiconnect-image-tool-<version> upload localhost:5000 --tls-verify=false
...
```

Providing a certificate for verification, or disabling TLS verification

See the sample output of the tool usage for options to provide a certificate for verification or to disable TLS verification:

```
$ docker run --rm apiconnect-image-tool-<version> upload --help
upload docker images

Usage:
  image-tool upload REGISTRY [flags]

Flags:
      --cert-dir string   Directory with destination registry certificate tls.crt file
      --username string   User name
  -h, --help              help for upload
      --password          password for <username>
      --tls-verify        Verify TLS on destination registry (default true)

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Notes:

- `--username=<username>` and `--password=<password>` can be used to specify credentials for authentication with the destination Docker registry.
- `--tls-verify=false` can be used to disable verification of the destination Docker registry certificate
- `--cert-dir <path>` can be used to provide a `tls.crt` file to be used for validation of the destination Docker registry certificate. For example:

```
docker run --rm -v <path-to-folder-with-tls.crt-file>:/cert apiconnect-image-tool-<version> upload <registry> --
cert-dir /cert
```

6. Download the file IBM® API Connect *<version>* Operator Release Files for Containers
   a. Decompress the downloaded Operator Release Files for Containers
   Contents:

   - API Connect Operator operator custom resource definition (CRDs).
   - API Connect Operator Deployment and required resources CRDs.
   - API Connect Operator Deployment and required resources CRDs, for multiple-namespace installations.
   - DataPower Gateway Operator operator custom CRDs.
   - API Connect custom resource templates, and Certificate Manager

   The Operator Release Files for Containers files will be used later in deployment instructions.

   Note: The Operator Release files may include catalog and operator source for OpenShift. These files are not used when deploying on native Kubernetes.

   b. To access the API Connect custom resource templates and Certificate Manager, decompress the archive `helper_files.zip`.
   The zip file contains custom resource templates for:

   - Deployment of each subsystem.
   - Backup and restore of each subsystem
   - Custom certificates, both external and internal, for either standard deployments or 2-site HA deployments
   - Certificate support for multi-namespace deployments
   - Multi-site secret generation in a two data center deployment on Kubernetes.
   - Ingress Issuer and Subsystem Certificates Resources, for either standard deployments or 2-site HA deployments
   - Setting an administrator secret for DataPower Gateway

   The templates will be used later in deployment instructions.

What to do next

Continue with Deploying operators and cert-manager.

- **Verifying the integrity of IBM product files**
  You can verify the integrity of files to ensure that they originated from IBM and are not modified.

Verifying the integrity of IBM product files

You can verify the integrity of files to ensure that they originated from IBM and are not modified.

Before you begin

Import the public key so you can use it to verify files. You only need to import the public key once.

1. Install **gpg** (GNU Privacy Guard), available at https://www.gnupg.org/.
2. Create a file called PRD0003216key.pub.gpg and copy the following content into the file:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----

mQINBGP+Fr0BEADz5ppiT+RhdOw+PihTcMirn4umuinsTU66qpWZES+aLmSjw3Ik
BUlD0GQkJDn6qqZyMhYUwaLVicTtLrChykzfkd3Cdzis0WRsCJNdpuLIV9OS8L9a

=1Zs0
-----END PGP PUBLIC KEY BLOCK-----
```

3. Run the following command to import the public key to **gpg**:

```
gpg --import PRD0003216key.pub.gpg
```

   For example:

```
$ gpg --import PRD0003216key.pub.gpg
gpg: key 020ED6B5DBE65F3B: public key "APIConnect <psirt@us.ibm.com>" imported
gpg: Total number processed: 1
gpg:               imported: 1
```

4. Run the following command to verify that the key was imported successfully:

```
gpg --list-key --fingerprint APIConnect
```

   Make sure that the output of the command matches the following information:

```
$ gpg --list-key --fingerprint APIConnect
pub   rsa4096 2023-02-28 [SCE]
      39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
uid           [ unknown] APIConnect <psirt@us.ibm.com>
```

Procedure

Complete the following steps to verify product files for API Connect:

1. Visit IBM Fix Central and download the appropriate signatures_*<version>*.zip file for the version of API Connect that you will install or upgrade to. Extract the signatures_*<version>*.zip file to the folder containing the files that you want to verify.
2. Verify individual API Connect files to compare each file's signature with the fingerprint of the public key.
   To verify a file, run the following command:

```
gpg --verify <file_to_verify>.asc
```

   For example, to verify helper_files.zip, ensure that it is stored in the same folder as the signatures file and run the following command:

```
gpg --verify helper_files.zip.asc
```

   Example of a successful verification:

```
$ gpg --verify helper_files.zip.asc
gpg: assuming signed data in 'helper_files.zip'
gpg: Signature made Mon 28 Sep 17:35:17 2020 PDT
gpg:                using RSA key 39ED16345FCDEDB5D6EDE860020ED6B5DBE65F3B
gpg: Good signature from "APIConnect <psirt@us.ibm.com>" [unknown]
gpg: WARNING: This key is not certified with a trusted signature!
gpg:          There is no indication that the signature belongs to the owner.
Primary key fingerprint: 39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
```

Example of a failed verification:

```
gpg: assuming signed data in 'helper_files.zip'
gpg: Signature made Tue 11 Jul 2023 09:28:02 PM PDT
gpg:                using RSA key 39ED16345FCDEDB5D6EDE860020ED6B5DBE65F3B
gpg: BAD signature from "APIConnect <psirt@us.ibm.com>" [unknown]
```

Deploying on Kubernetes

Use the procedures in this section to install API Connect on native Kubernetes distributions.

- **Deploying operators and cert-manager**
  Deploy the Kubernetes operator files and install cert-manager.
- **Installing the API Connect subsystems**
  Deploy the API Connect subsystem custom resources.
- **Installing a two data center deployment on Kubernetes**
  Additional installation instructions for a two data center disaster recovery (2DCDR) deployment on Kubernetes.
- **Troubleshooting installation on Kubernetes**
  Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on Kubernetes

Deploying operators and cert-manager

Deploy the Kubernetes operator files and install cert-manager.

Before you begin

You must have completed the following installation tasks before you deploy the operators:

1. Review the installation requirements. See Deployment requirements.
2. Obtain the API Connect product files. See Obtaining product files.

About this task

Table 1 lists the operators used for installing and upgrading API Connect.

Table 1. Operators and operands for API Connect

API Connect version	API Connect Operator version	DataPower Operator version
10.0.8.2-ifix1	5.4.1	1.11.5

Note: There can be only one instance of the API Connect operator in your Kubernetes environment. You cannot have multiple namespaces each with their own API Connect operator.
You can run the API Connect operator and subsystems at different versions. The following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
5.4.1	• 10.0.8.2-ifix1 • 10.0.8.1 • 10.0.8.0
5.3-sc2	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

The deployment procedures differ depending on whether your deployment cluster uses a single namespace or multiple namespaces. Follow the instructions that apply to your deployment cluster:

- **Deploying operators in a single-namespace API Connect cluster**
  Deploy the Kubernetes operator files in a single namespace cluster.
- **Deploying operators in a multi-namespace API Connect cluster**
  Deploy the Kubernetes operator files in multi-namespace cluster.
- **Installing cert-manager and certificates in a two data center deployment**
  Additional instructions explaining how to install a cert-manager and certificates in a two data center disaster recovery deployment on Kubernetes.
- **Customizing certificates during installation on Kubernetes**
  How to customizing your user-facing and internal API Connect certificates during installation.

Deploying operators in a single-namespace API Connect cluster

Deploy the Kubernetes operator files in a single namespace cluster.

Before you begin

- Ensure you completed the prerequisite tasks for installing operators. See Deploying operators and cert-manager.
- Be sure to review your strategy for using certificates with API Connect. See Deployment requirements.

Note: If you are deploying a multi-namespace API Connect cluster, do not use these instructions. Instead, go to Deploying operators in a multi-namespace API Connect cluster.

Procedure

1. Ensure `KUBECONFIG` is set for the target cluster:

   ```
   export KUBECONFIG=<path_to_cluster_config_YAML_file>
   ```

   An example path is `/Users/user/.kube/clusters/<cluster_name>/kube-config-<cluster_name>.yaml`

2. Decide on a namespace to be used for installation.
   If not using the default namespace, create the namespace in the Kubernetes cluster where the API Connect deployment will take place. Use the following command, replacing `<namespace>` with the namespace for the deployment:

   ```
   kubectl create ns <namespace>
   ```

   Note: The following namespaces are reserved and must not be used for your installation:
   - `default`
   - `openshift-*`
   - `kube-*`
3. Install a cert-manager.
   Cert-manager adds convenience to the generation and management of API Connect certificates. For more information about cert-manager, see Key Concepts: Cert-manager, Issuers, and Secrets.

   Note: If you are deploying a two data center disaster recovery deployment on Kubernetes, then do not do this step, follow the steps in Installing cert-manager and certificates in a two data center deployment, then return here.
   a. Obtain the certificate manager.
      API Connect uses cert-manager v1.16.3 of cert-manager, which is a native Kubernetes certificate management controller.

      You can obtain cert-manager v1.16.3 from the API Connect v10 distribution `helper_files.zip` archive, or download it from https://github.com/cert-manager/cert-manager/releases/tag/v1.16.3

   b. Apply the CR:

      ```
      kubectl apply -f cert-manager-1.16.3.yaml
      ```

      Do not specify a custom namespace.

      See https://cert-manager.io/docs/release-notes/release-notes-1.16/.

   c. Wait for `cert-manager` pods to enter `Running 1/1` status before proceeding. To check the status:

      ```
      kubectl get po -n cert-manager
      ```

      There are 3 `cert-manager` pods in total.
4. Create a registry secret with credentials to be used to pull down product images.
   Use the following command, replacing `<namespace>` with the namespace for your deployment, and replacing `<registry_server>` with the location of the Docker Registry where the installation product images were pushed:

   ```
   kubectl create secret docker-registry apic-registry-secret
   --docker-server=<registry_server>
   --docker-username=<username@example.com> --docker-password=<password> --docker-email=<username@example.com> -n <namespace>
   ```

5. Create a registry secret for the DataPower registry with the credentials to be used to pull down product images.
   Use the following command, replacing `<namespace>` with the desired namespace for the deployment:

   ```
   kubectl create secret docker-registry datapower-docker-local-cred
   --docker-server=<docker_server> --docker-username=<username@example.com> --docker-password=<password> --docker-email=
   <username@example.com> -n <namespace>
   ```

6. Create a DataPower admin secret.
   Use the following command, replacing `<namespace>` with the desired namespace for the deployment:

   ```
   kubectl create secret generic datapower-admin-credentials --from-literal=password=admin -n <namespace>
   ```

   The admin secret will be used for `$ADMIN_USER_SECRET` when deploying the gateway CR.

7. If you are using a namespace other than `default`, open `ibm-apiconnect.yaml` in a text editor. Replace each occurrence of `default` with the namespace for your deployment.
8. Open `ibm-apiconnect.yaml` in a text editor. Replace the value of each `image:` key with the location of the API Connect operator images (from the `ibm-apiconnect` container and the `ibm-apiconnect-init` container), either uploaded to your own registry or pulled from a public registry.

   ```
     serviceAccountName: ibm-apiconnect
      imagePullSecrets:
      - name: apic-registry-secret
      initContainers:
      - name: ibm-apiconnect-init
       image: <My_registry_or_public_registry>/ibm-apiconnect-operator-
   init@sha256:0d3bbac7c67372ad013407a8049c69dbd08b1559b59a7606fcd87eb0f4519ce1
   ...
      containers:
       - name: ibm-apiconnect
       image: <My_registry_or_public_registry>/ibm-apiconnect-
   ```

```
operator@sha256:a7473ee26c252fca4931b682cd95d73b4149e4b5b773834408f9f22d0246a76c
```

9. If DataPower Gateway is desired in this installation, and if you are using a namespace other than `default`, open `ibm-datapower.yaml` in a text editor. Replace each occurrence of `default` with the namespace for your deployment.
10. Open `ibm-datapower.yaml` in a text editor.
    a. Locate the `image:` key in the containers section of the deployment yaml immediately after `imagePullSecrets:`. Replace the value of the `image:` key with the location of the `datapower` operator image, either uploaded to your own registry or pulled from a public registry.
    b. Update the `IBM_DOCKER_HUB` and `IBM_ENTITLED_REGISTRY` value in the `env` section with the registry address where the images were uploaded with the image-tool in Obtaining product files.
    For example, the default entries are:

```
            - name: IBM_ENTITLED_REGISTRY
              value: "cp.icr.io/cp/datapower"
            - name: IBM_DOCKER_HUB
              value: "cp.icr.io/cp/datapower"
```

11. Install the ibm-apiconnect CRDs.

```
kubectl apply --server-side --force-conflicts -f ibm-apiconnect-crds.yaml
```

12. Install the ibm-apiconnect Kubernetes deployment.

```
kubectl apply -f ibm-apiconnect.yaml
```

13. If DataPower Gateway is desired in this installation, install the ibm-datapower Kubernetes deployment for DataPower Gateway, with the following command, replacing `<namespace>` with the desired namespace for the deployment (`-n <namespace>` may be omitted if default namespace is being used for installation):

```
kubectl apply -f ibm-datapower.yaml -n <namespace>
```

Troubleshooting: If your DataPower operator pod fails to start, see Troubleshooting install.

14. Install the `ingress-ca` Issuer to be used by `cert-manager`.
    Note:
    If you are installing a two data center disaster recovery deployment, skip this step, and follow the steps in: Installing cert-manager and certificates in a two data center deployment.

    a. Use the following command, replacing `<namespace>` with the desired namespace for the deployment:

```
kubectl apply -f ingress-issuer-v1.yaml -n <namespace>
```

    The file `ingress-issuer-v1.yaml` is included in the release files contained in `helper_files.zip`

    b. Validate that the command succeeded:

```
kubectl get certificates -n <namespace>
```

    Example output indicating success:

```
NAME                          READY   SECRET                        AGE
analytics-ingestion-client    True    analytics-ingestion-client    70s
gateway-peering               True    gateway-peering               69s
gateway-service               True    gateway-service               69s
ingress-ca                    True    ingress-ca                    71s
portal-admin-client           True    portal-admin-client           71s
portal-tunnel-client          True    portal-tunnel-client          70s
```

    The list of certificates might vary based on your deployment.

15. Continue with Installing the API Connect subsystems.

Deploying operators in a multi-namespace API Connect cluster

Deploy the Kubernetes operator files in multi-namespace cluster.

Before you begin

- Ensure you completed the prerequisite tasks for installing operators. See Deploying operators and cert-manager.
- Be sure to review your strategy for using certificates with API Connect. See Deployment requirements.

About this task

Note: If you are deploying a single-namespace API Connect cluster, do not use these instructions. Instead, go to Deploying operators in a single-namespace API Connect cluster.

- These instructions apply only to native k8s deployments. They do not apply to OpenShift deployments.
- The API Connect operator is deployed as a cluster-scoped operator which watches every namespace in the cluster. The API Connect operator can be installed in any namespace, although it is recommended that the operator is installed in its own dedicated namespace.
- The DataPower operator must be deployed in a namespace where gateway subsystem install is planned.
- Single `ingress-ca` certificate must be installed and used across the various namespaces where subsystems will be installed.

Procedure

1. Prepare your environment:
   a. Ensure `KUBECONFIG` is set for the target cluster:

      ```
      export KUBECONFIG=<path_to_cluster_config_YAML_file>
      ```

      An example path is `/Users/user/.kube/clusters/<cluster_name>/kube-config-<cluster_name>.yaml`

   b. Create namespaces for the subsystems that will be installed:
      - API Connect operator namespace
      - Gateway subsystem namespace
      - Management subsystem namespace
      - Portal subsystem namespace
      - Analytics subsystem namespace

      Note: The following namespaces are reserved and must not be used for your installation:
      - `default`
      - `openshift-*`
      - `kube-*`

      The following example values and deployment are used throughout these instructions:

      - An apiconnect operator is installed in `operator` namespace
      - A DataPower operator and gateway subsystem is installed in `gtw` namespace
      - The Management subsystem is installed in `mgmt` namespace
      - The Portal subsystem is installed in `portal` namespace
      - The Analytics subsystem is installed in `a7s` namespace

   c. Multi-namespace templates are provided in `helper_files.zip`, inside the `release_files.zip` you downloaded in Obtaining product files:

      ```
      helper_files_unpack/multi-ns-support/
      ```

2. Install cert-manager and configure certificates:
   Cert-manager adds convenience to the generation and management of API Connect certificates. For more information about cert-manager, see Key Concepts: Cert-manager, Issuers, and Secrets.

   You can obtain cert-manager v1.16.3 from the API Connect v10 distribution `helper_files.zip` archive, or download it from https://github.com/cert-manager/cert-manager/releases/tag/v1.16.3.

   a. Install cert-manager v1.16.3, do not specify a custom namespace as cert manager will be installed in its own namespace.
      Note: If you are deploying a two data center disaster recovery deployment on Kubernetes, then do not do this step, follow the steps in Installing cert-manager and certificates in a two data center deployment, then return here.

      i. `kubectl apply -f cert-manager-1.16.3.yaml`

      ii. Wait for cert-manager pods to enter `Running 1/1` status before proceeding. Use the following command to check:

      ```
      kubectl -n cert-manager get po
      ```

      There are 3 cert-manager pods in total.

   b. Install `ingress-ca` certificate:
      i. Locate `ingress-ca` certificate at `helper_files/multi-ns-support/ingress-ca-cert.yaml`
      ii. Create `ingress-ca` certificate in one of the subsystems. For example, if we choose `mgmt` namespace:

      ```
      kubectl -n mgmt apply -f ingress-ca-cert.yaml
      ```

   c. Install common issuers on all the namespaces:
      i. Locate `common-issuer.yaml` in `helper_files/multi-ns-support/`
      ii. Create `common-issuer.yaml` in all namespaces:

      ```
      kubectl create -f common-issuer.yaml -n mgmt
      kubectl create -f common-issuer.yaml -n gtw
      kubectl create -f common-issuer.yaml -n ptl
      kubectl create -f common-issuer.yaml -n a7s
      ```

   d. Obtain the `ingress-ca` secret created by cert manager and create the secret on all namespaces:
      Note: The instructions in this step result in having a `selfsigning-issuer` in every namespace. This issuer is typically referenced by an API Connect CR in the namespace with:

      ```
      ...
        microServiceSecurity: certManager
        certManagerIssuer:
          name: selfsigning-issuer
          kind: Issuer
      ...
      ```

      This issuer (and associated root certificate) does not need to be the same in every namespace, nor does it need to be the same for 2 CRs in the same namespace. Each subsystem can use its own `selfsigning-issuer`, because it is only used for certificates that are internal to the subsystem.

      To ensure that the ingress-issuer is in sync across namespaces, it should be backed by the same `ingress-ca` certificate. This enables, for example, APIM to use a client certificate that matches the CA of the portal-admin ingress endpoint. The sync is achieved by copying around the `ingress-ca` certificate in each namespace, as shown in the following steps. It does not matter that it is the same issuer, or whether it has a different name. However it is important is that the ingress-ca is the same for the all the "ingress-issuer" that are going to be used by the subsystems.

      i. Make sure `ingress-ca` certificate READY status is set to true:

      ```
      kubectl get certificate ingress-ca -n mgmt
      NAME         READY   SECRET       AGE
      ingress-ca   True    ingress-ca   9m24s
      ```

      ii. Cert-manager creates a secret called `ingress-ca` in `mgmt` namespace which represents the certificate we created in Step 2.c.

iii. Use the following command to obtain the yaml format of the secret:

```
kubectl get secret ingress-ca -n <namespace-where-ingress-ca-cert-is-created> -o yaml > ingress-ca-secret-in-cluster.yaml
```

iv. Remove unwanted content from the secret yaml:

```
cat ingress-ca-secret-in-cluster.yaml | grep -v 'creationTimestamp' | grep -v 'namespace' | grep -v 'uid' | grep -v 'resourceVersion' > ingress-ca-secret.yaml
```

v. Create the secret using the YAML that you prepared in previous step on rest of the subsystem namespaces. In this example, in the **gtw**, **a7s** and **ptl** namespaces.

```
kubectl create -f ingress-ca-secret.yaml -n gtw
kubectl create -f ingress-ca-secret.yaml -n ptl
kubectl create -f ingress-ca-secret.yaml -n a7s
```

e. Install management certs in management namespace:
   i. Locate **management-certs.yaml** in **helper_files/multi-ns-support/**
   ii. Create **management-certs.yaml** in the **mgmt** namespace:

```
kubectl create -f management-certs.yaml -n mgmt
```

f. Install gateway certs in the gateway namespace:
   i. Locate **gateway-certs.yaml** in **helper_files/multi-ns-support/**
   ii. Create **gateway-certs.yaml** in the **gtw** namespace:

```
kubectl create -f gateway-certs.yaml -n gtw
```

3. Install the API Connect operator:
   a. Install the ibm-apiconnect CRDs with the following command. Do not specify a namespace:

```
kubectl apply --server-side --force-conflicts -f ibm-apiconnect-crds.yaml
```

   b. Create a registry secret with the credentials to be used to pull down product images with the following command, replacing **<*namespace*>** with the desired namespace for the API Connect operator deployment.

```
kubectl -n <namespace> create secret docker-registry apic-registry-secret
              --docker-server=<registry_server>
              --docker-username=<username@example.com> --docker-password=<password>
              --docker-email=<username@example.com>
```

   - For example, replace **<*namespace*>** with **operator**.
   - **docker-password** can be your artifactory API key.
   - **-n <namespace>** may be omitted if **default** namespace is being used for installation

   c. Locate and open **ibm-apiconnect-distributed.yaml** in a text editor of choice. Then, find and replace each occurrence of **$OPERATOR_NAMESPACE** with **<namespace>**, replacing **<namespace>** with the desired namespace for the deployment. In this example, the namespace is **operator**.
   d. Also in **ibm-apiconnect-distributed.yaml**, replace all the instances of the placeholder string **REPLACE-DOCKER-REGISTRY** with the docker registry host location of the apiconnect operator image (either uploaded to your own registry or pulled from the public registry).
   e. Install **ibm-apiconnect-distributed.yaml** with the following command

```
kubectl apply -f ibm-apiconnect-distributed.yaml
```

4. Install DataPower operator:
   Deployment of the DataPower operator is only needed if you have at least one API Connect v10 Gateway subsystem (whether v5 compatible or not) to upgrade. If you are using DataPower in a different form factor such as an Appliance, you will not have an API Connect v10 Gateway subsystem to upgrade, and will not need the DataPower operator for your upgrade.

   Note: The DataPower Operator supports multiple instances of DataPower in the same cluster, separated by namespace. When deploying into multiple namespaces, ensure that any cluster-scoped resources are created with unique names for separate installations, such that they are not overwritten by subsequent installations. For example, DataPower cluster-scoped resources include **ClusterRoleBindings**.
   a. Create a registry secret for the DataPower registry with the credentials to be used to pull down product images with the following command, replacing **<namespace>** with the desired namespace for the deployment .(In this case **gtw**):

```
kubectl -n <namespace> create secret docker-registry datapower-docker-local-cred
              --docker-server=<registry_server>
              --docker-username=<username@example.com> --docker-password=<password>
              --docker-email=<username@example.com>
```

   - For example, replace **<*namespace*>** with **gtw**.
   - **docker-password** can be your artifactory API key.
   - **-n <namespace>** may be omitted if **default** namespace is being used for installation

   b. Create a DataPower admin secret, replacing **<namespace>** with the desired namespace for the deployment. For example, **gtw**. This secret will be used for **$ADMIN_USER_SECRET** later in the Gateway CR:

```
kubectl -n <namespace> create secret generic datapower-admin-credentials --from-literal=password=admin
```

   -n
   <namespace> may be omitted if **default** namespace is being used for installation.

   c. Locate and open **ibm-datapower-distributed.yaml** in a text editor of choice. Then, find and replace each occurrence of **default** with **<namespace>**, replacing **<namespace>** with the desired namespace for the deployment. For example, **gtw**.
   d. Install **ibm-datapower-distributed.yaml** with the following command:

```
kubectl -n <namespace> apply -f ibm-datapower-distributed.yaml
```

   Troubleshooting: If your DataPower operator pod fails to start, see Troubleshooting install.

5. Next, install the subsystems. Continue with Installing the API Connect subsystems.

Note: Unless otherwise stated, when performing the individual subsystem upgrades the **<*namespace*>** value of example **kubectl** commands for a given subsystem should be set to the namespace for the particular subsystem component they are acting on.

Installing cert-manager and certificates in a two data center deployment

Additional instructions explaining how to install a cert-manager and certificates in a two data center disaster recovery deployment on Kubernetes.

Before you begin

Before you install a cert-manager, you should know your strategy for using certificates with API Connect. Review the certificate requirements in Deployment requirements.

You should also have already completed Obtaining product files.

About this task

You must create certificates and keys for API Manager and the Developer Portal on both data centers, dc1 and dc2, and ensure that they match on both.

Use these instructions to install the supplied cert-manager and **ingress-issuer-v1.yaml**.

Note that **ingress-issuer-v1.yaml** is supplied by cert-manager.

Procedure

1. Install cert-manager.
   Cert-manager adds convenience to the generation and management of API Connect certificates. For more information about cert-manager, see Key Concepts: Cert-manager, Issuers, and Secrets.

   a. Obtain the certificate manager.
   API Connect v10 uses cert-manager v1.16.3 of cert-manager, which is a native Kubernetes certificate management controller.

   You can obtain cert-manager v1.16.3 from the API Connect v10 distribution **helper_files.zip** archive, or download it from https://github.com/cert-manager/cert-manager/releases/tag/v1.16.3

   b. Apply the CR:

   ```
   kubectl apply -f cert-manager-1.16.3.yaml
   ```

   Do not specify a custom namespace.

   See https://cert-manager.io/docs/release-notes/release-notes-1.16/.

   c. Wait for **cert-manager** pods to enter **Running 1/1** status before proceeding. To check the status:

   ```
   kubectl get po -n cert-manager
   ```

   There are 3 **cert-manager** pods in total.
2. Use the following steps to allow **ingress-ca** secrets to be the same on both data centers.
   a. On DC1 apply the file **ingress-issuer-v1-dc1.yaml**:

   ```
   kubectl -n <namespace> apply -f ingress-issuer-v1-dc1.yaml
   ```

   b. Validate that the command succeeded:

   ```
   kubectl get certificates -n <namespace>
   ```

   c. Export **ingress-ca** secret as a yaml from DC1:

   ```
   kubectl -n <namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
   ```

   d. Edit the **ingress-ca.yaml** file to remove all **annotations**, **labels**, **creationTimestamp**, **managedFields**, **manager**, **operation**, **time**, **resourceVersion**, **selfLink**, and **uid**. Also, if you are using a different **namespace** in DC2, then update the **namespace** field.
   e. Copy the **ingress-ca.yaml** from DC1 to DC2 and apply that file on DC2:

   ```
   kubectl -n <namespace> apply -f ingress-ca.yaml
   ```

   f. On DC2 apply the file **ingress-issuer-v1-dc2.yaml**:

   ```
   kubectl -n <namespace> apply -f ingress-issuer-v1-dc2.yaml
   ```

   g. Use the following commands to test that they are the same, on DC1 run:

   ```
   kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d
   > /tmp/ingress.pem.dc1
   ```

   h. On DC2 run:

   ```
   kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}' | base64 -d
   > /tmp/ingress.pem.dc2
   ```

   i. To see the differences run:

   ```
   diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
   ```

   The files should be the same.

j. On DC2, to ensure that the certificates are working correctly and that they are using the `ingress-ca` secret. First, get the `portal-admin-client crt` file:

```
kubectl -n <namespace> get secrets portal-admin-client -o yaml | grep tls.crt | awk '{print $2}' | base64 -d > /tmp/admin-client.crt
```

k. Test that it is working by using OpenSSL:

```
openssl verify -verbose -CAfile /tmp/ingress.pem.dc1 /tmp/admin-client.crt
```

If it is working, you should see:

```
/tmp/admin-client.crt: OK
```

3. Continue with Deploying operators and cert-manager.

Customizing certificates during installation on Kubernetes

How to customizing your user-facing and internal API Connect certificates during installation.

Note: The recommended best practice is to not customize your internal certificates, and to customize your user-facing certificates after API Connect is installed. If you do customize certificates, then you are responsible for maintaining those certificates. Ensure that your custom certificates meet the requirements that are defined in the Certificate reference tables (which are subject to change in future fix packs), and that you renew them before they expire. Follow the topics in this section only if you must customize internal certificates.
To deploy API Connect with custom internal certificates, some additional preparation and steps are required before any API Connect subsystem CRs are created. Review the topics in this section before you start the installation process.

Remember: As per the DNS specification, wildcard certificates apply only to one level of subdomain and not more than that. For example, a certificate for `*.example.com` is not valid for `foo.bar.example.com`.
Customization of the following certificates is supported:

Table 1. Management subsystem certificates

Certificate name	Issuer	Description

`analytics-ingestion-client or a7s-ing-client`	`ingress-issuer`	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have:
		• The same CA as the server certificate `analytics-ai-endpoint` on the analytics subsystem.
		• The common name must match the `spec.clientSubjectDN` in the analytics CR:
		`kubectl describe cert analytics-admin-client`
		`Spec:`
		`  Common Name:  a7s-ing-client`
		`kubectl get a7s -o yaml`
		`  spec:`
		`    clientSubjectDN: CN=a7s-ing-client`
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=a7s-ingestion-client`, or they could both be `CN=a7s-ingestion-client, O=cert-manager`, but they must be identical.
		To update this certificate, use kubectl. Restart the `apim`, `taskmanager`, and `analytics-proxy` pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
		This certificate is loaded by the management subsystem into the `Analytics ingestion TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the analytics subsystem, then create a new profile and specify it when you register the analytics service.

`portal-admin-client or ptl-adm-client`	`ingress-issuer`	Client certificate used for communication with the portal subsystem on the `portalAdminEndpoint`. This certificate must have:
		• The same CA as the server certificate `portal-admin or ptl-director` on the portal subsystem.
		• The common name must match the `spec.adminClientSubjectDN` in the portal CR:
		`kubectl describe cert portal-admin-client`
		`Spec:`
		`  Common Name:  ptl-adm-client`
		`kubectl get ptl -o yaml`
		`  spec:`
		`    adminClientSubjectDN: CN=ptl-adm-client`
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=portal-admin-client`, or they could both be `CN=ptl-adm-client, O=cert-manager`, but they must be identical.
		This certificate is loaded by the management subsystem into the `Portal Director TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the portal, then create a new profile and specify it when you register the portal service.

Certificate name	Issuer	Description
`gateway-client-client or gw-dr-client`	`ingress-issuer`	Client certificate for communications with the gateway service. Restart the **`apim`** and **`taskmanager`** pods after update. This certificate must have the same CA as the **`gwv6-manager-endpoint or gw-gateway-manager`** certificate on the gateway. This certificate is loaded by the management subsystem into the **`Gateway management client TLS client profile`** that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the gateway, then create a new profile and specify it when you register the gateway service.
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.
`api-endpoint or mgmt-platform-api`	`ingress-issuer`	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
`consumer-endpoint or mgmt-consumer-api`	`ingress-issuer`	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.

Table 2. Analytics subsystem certificates

Certificate name	Issuer	Description
`analytics-ai-endpoint or a7s-ai-endpoint`	`ingress-issuer`	Server certificate used on the analytics ingestion endpoint, in the **`mtls-gw`** pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the **`analytics-ai-endpoint`** certificate. If this certificate is updated, restart the **`mtls-gw`** pod for the update to take effect.

Table 3. Gateway certificates

Certificate name	Issuer	Description
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The **`gatewayManager`** endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the **`gateway-client-client`** certificate on management subsystem If you update this certificate, then all gateway pods are restarted automatically.
`gwv5-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The **`gatewayManager`** endpoint certificate for the v5 compatible gateway. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the **`gateway-client-client`** certificate on management subsystem If you update this certificate, then all gateway pods are restarted automatically.
`gwv6-endpoint or gw-gateway`	`ingress-issuer`	Legacy certificate that is not used.
`gwv5-endpoint or gw-gateway`	`ingress-issuer`	Legacy certificate that is not used.

Table 4. Portal subsystem certificates

Certificate name	Issuer	Description
`portal-admin or ptl-director or portal-director`	`ingress-issuer`	Server certificate used on the **`portalAdminEndpoint`**. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the **`portal-admin-client`** certificate. This certificate must have the same CA as the **`portal-admin-client`** certificate on the management subsystem. This certificate is used by the **`portal-nginx`** pod.
`portal-web`	`ingress-issuer`	The server certificate used on the **`portalUIEndpoint`**. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default **`portal-web`** certificate is issued by the **`ingress-issuer`**, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate. This certificate is used by the **`portal-web`** ingress (**`portal-web`** route on OpenShift).

Table 5. Internal intra-subsystem certificates

Certificate name	`spec.customCertificates` name	Description
`management-ca`	`caCertificate`	The issuer for the management subsystems intra-subsystem certificates: management-client, management-server, postgres, and nats certificates. Communication between management subsystem pods fails if there is a problem with this certificate. This certificate is also used as the CA for REST API calls to the management subsystem from the other subsystems, when using **`in-cluster`** communication. See In-cluster service communication between subsystems
`portal-ca`	`caCertificate`	The issuer for the portal-client and portal-server certificates. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.

Certificate name	spec.customCertificates name	Description
analytics-ca	caCertificate	The issuer for the analytics-client and analytics-server certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If you update this certificate, you must then update the analytics-client and analytics-server server certificates, and then ensure that the following pods are restarted: • storage: Restarts automatically. • warehouse: Restarts automatically. • ingestion: Restarts automatically. • director: Restart manually.
management-client	clientCertificate	Client certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.
portal-client	clientCertificate	Client certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.
analytics-client	clientCertificate	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, then the storage, warehouse and ingestion pods restart automatically. You must manually restart the director pod.
management-server	serverCertificate	Server certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate. Required DNS names within the SAN section are: *.<namespace> *.<namespace>.svc *.<namespace>.svc.cluster.local *.<instance name>-server.<namespace>.svc *.<instance name>-server.<namespace>.svc.cluster.local <instance name>-server
portal-server	serverCertificate	Server certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. Required DNS names within the SAN section are: *.<namespace> *.<namespace>.svc *.<namespace>.svc.cluster.local *.<instance name>-server.<namespace>.svc *.<instance name>-server.<namespace>.svc.cluster.local <instance name>-server *.<instance name>-<site name>-db-all.<namespace>.svc *.<instance name>-<site name>-www-all.<namespace>.svc *.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local *.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local *.<namespace>.svc.cluster.local <instance name>-db #<remote portal CR name>-db # For 2DCDR only. <*instance name*> and <*remote portal CR name*> are truncated if more than 15 characters. This certificate is used by all portal pods.
analytics-server	serverCertificate	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. Required DNS names within the SAN section are: *.<namespace> *.<namespace>.svc *.<namespace>.svc.cluster.local *.<instance name>-server.<namespace>.svc *.<instance name>-server.<namespace>.svc.cluster.local <instance name>-server <instance name>-storage <instance name>-director <instance name>-ingestion <instance name>-mtls-gw <instance name>-storage-os-master <instance name>-warehouse If this certificate is updated, then the storage, warehouse and ingestion pods restart automatically. You must manually restart the director pod.
db-server	dbServerCertificate	Intra-subsystem certificate for the management database.
natscluster-mgmt	NATSTLSCertificate	Intra-subsystem certificate for the nats pods.
db-client-postgres	dbClientPostgres	Intra-subsystem certificate for the management database subsystem.
db-client-apicuser	dbClientApicuser	Intra-subsystem certificate for the management database subsystem.

To see the complete list of TLS certificates, see API Connect TLS certificates.

Note: The API invocation certificate that callers to the published APIs on your gateways see is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.
You can replace the default certificates with certificates that you already own, for example DigiCert certificates, or generate new custom certificates by using software such as cert-manager.

- If you have your own certificates, see Generating custom certificates manually.
- If you do not have your own custom certificates, and you want to use cert-manager to generate custom certificates, see Generating custom certificates using cert-manager.

If you want to customize API Connect internal certificates (the certificates for communication within API Connect components), then you must customize all of them, but you do not need to create all of them yourself. Any custom internal certificates that are not named in your subsystem CRs are generated automatically during installation. You cannot convert an existing API Connect installation to use custom internal certificates, these certificates must be configured at installation.

Setting an encryption-secret for the management database using OpenSSL

You can optionally create an encryption-secret for the management database. If you do not create an encryption-secret, then it is created automatically for you.

1. The encryption-secret is a secure random bytes password that is used for field level encryption in the management database. You can generate 128 random bytes using the following command in OpenSSL:

   ```
   openssl rand -out /path/to/secret/encryption-secret.bin 128
   ```

2. Use kubectl to put the generated secret into `management-encryption-key`:

   ```
   kubectl create secret generic management-encryption-key -n <namespace>
         --from-file=/path/to/secret/encryption_secret.bin
   ```

   where **<namespace>** is the namespace where the management CR is going to be created)

3. Make sure that in management_cr.yaml, `encryptionSecret.secretName` points to the name of the secret created in the previous step.

Important: Back up the encryption-secret.bin file to a safe location. If this file is lost, then it is not possible to access the management database or its backups.

Generating custom certificates using cert-manager

Generate custom certificates using cert-manager.

About this task

If you do not have your own custom certificates that you can provide for the installation, you can prepare a YAML file with certificate definitions that cert-manager can use to generate the required certificates.
Note: The API invocation certificate that callers to the published APIs on your gateways see is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.

Procedure

1. Download and install cert-manager v1.16.3 from https://github.com/cert-manager/cert-manager/releases/tag/v1.16.3.
2. Open the helper_files/custom-certs-external.yaml in an editor.
   To locate the custom-certs-external.yaml file, see Obtaining product files.
3. In custom-certs-external.yaml, replace all instances of `example.com` with the domain for your API Connect deployment.
4. Apply the custom-certs-external.yaml file in your API Connect namespace.

   ```
   kubectl -n <namespace> apply -f custom-certs-external.yaml
   ```

5. Optional: If you want to customize the internal certificates with cert-manager, then follow these steps.
   Note: It is not recommended to customize internal certificates because it adds complexity and increases the maintenance overhead of your API Connect deployment. It is not possible to customize a subset of the internal certificates in a subsystem CR. If you want to customize any of the internal certificates in a subsystem CR, then you must customize them all.
   Use the custom-certs-internal.yaml file, which can be found in the `helper_files` installation archive. For more information, see Obtaining product files.

   a. Decide on a site name for your management subsystem. The `db-server-certificate` requires a site-name. Update the custom-certs-internal.yaml file with your site name and namespace.
   b. Apply the updated custom-certs-internal.yaml file in your API Connect namespace:

      ```
      kubectl -n <namespace> apply -f custom-certs-internal.yaml
      ```

6. Verify that the certificates and their corresponding secrets were created:

   ```
   kubectl -n <namespace> get certificate
   kubectl -n <namespace> get secret
   ```

What to do next

Configure your subsystem CR YAML files to use your custom certificates: Deploying API Connect subsystems with custom certificates.

Generating custom certificates using cert-manager in a two data center deployment

Generate custom certificates using cert-manager in a two data center disaster recovery deployment on Kubernetes.

About this task

The following example of providing custom certificates uses cert-manager to generate them.

Procedure

1. Set **KUBECONFIG** for the target cluster:

   ```
   export KUBECONFIG=<path_to_cluster_config_YAML_file>
   ```

   Example path:

   ```
   /Users/user/.kube/clusters/<cluster_name>/kube-config-<cluster_name>.yaml
   ```

2. Install cert-manager:
   a. Download v1.16.3 from https://github.com/cert-manager/cert-manager/releases/tag/v1.16.3.
   b. Install cert-manager. Do not specify a namespace:

   ```
   kubectl apply -f cert-manager.yaml
   ```

   c. Check the status of the **cert-manager** pods:

   ```
   kubectl -n cert-manager get pods
   ```

   Wait for **cert-manager** pods to enter **Running 1/1** status before proceeding. Cert-manager has 3 pods in total.

3. Set up the customized external certificates:
   For quick setup, you can use the provided YAML files that are included in the **helper_files**, see Deploying operators and cert-manager. The YAML for the active data center (DC1) is called **custom-certs-external-dc1.yaml** and the YAML for the warm-standby data center (DC2) is called **custom-certs-external-dc2.yaml**.

   a. Open **custom-certs-external-dc1.yaml** and **custom-certs-external-dc2.yaml** in a text-editor. Find and replace each occurrence of **example.com** with the ingress subdomain for your API Connect deployment.
   b. Ensure that the management CR for DC1 is ready to be installed. Make a note of the **hostname** of the site.
   c. In **custom-certs-external-dc1.yaml** find **spec.dnsNames**
   For example, in DC1:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: dc1-mgmt-replication
   spec:
     commonName: dc1-mgmt-replication
     secretName: dc1-mgmt-replication
     dnsNames:
     - <INSERT SITE HOSTNAME HERE. THIS WILL BE THE SAME VALUE AS IN THE MANAGEMENT CR spec.multiSiteHA.hosts.name for
   site 1>
     issuerRef:
       name: ingress-issuer
     usages:
     - "signing"
     - "key encipherment"
     duration: 17520h # 2 years
     renewBefore: 720h # 30 days
     privateKey:
       rotationPolicy: Always
   ```

   d. Replace the line that begins **- <INSERT SITE HOSTNAME HERE** with - *hostname of the site*.
   e. Ensure that the management CR for DC2 is ready to be installed. Make a note of the **hostname** of the site.
   f. In **custom-certs-external-dc2.yaml** find **spec.dnsNames** and replace the line that begins **- <INSERT SITE HOSTNAME HERE** with - *hostname of the site*.
   g. Ensure that the portal CR for DC1 is ready to be installed. Make a note of the **hostname** of the site.
   h. In **custom-certs-external-dc1.yaml** find **spec.dnsNames**
   For example, in DC1:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: dc1-ptl-replication
   spec:
     commonName: dc1-ptl-replication
     secretName: dc1-ptl-replication
     dnsNames:
     - <INSERT SITE HOSTNAME HERE. THIS WILL BE THE SAME VALUE AS IN THE PORTAL CR spec.multiSiteHA.hosts.name for site
   1>
       issuerRef:
       name: ingress-issuer
     usages:
     - "signing"
     - "key encipherment"
     duration: 17520h # 2 years
     renewBefore: 720h # 30 days
   ```

```
  privateKey:
    rotationPolicy: Always
```

i. Replace the line that begins `- <INSERT SITE HOSTNAME HERE>` with `- hostname of the site`.
j. Ensure that the portal CR for DC2 is ready to be installed. Make a note of the `hostname` of the site.
k. In `custom-certs-external-dc2.yaml` find `spec.dnsNames` and replace the line that begins `- <INSERT SITE HOSTNAME HERE>` with `- hostname of the site`.

4. Use the following steps to synchronize the `ingress-ca` secrets across the data centers.
   a. On DC1 apply the file `custom-certs-external-dc1.yaml`:

```
kubectl -n <namespace> apply -f custom-certs-external-dc1.yaml
```

   b. Validate that the command succeeded:

```
kubectl get certificates -n <namespace>
```

   c. Export `ingress-ca` secret as a YAML file from DC1:

```
kubectl -n <namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
```

   d. Edit the `ingress-ca.yaml` file to remove all labels, annotations, `creationTimestamp`, `resourceVersion`, `uid`, and `selfLink`.
   e. Copy the `ingress-ca.yaml` from DC1 to DC2 and apply that file on DC2:

```
kubectl -n <namespace> apply -f ingress-ca.yaml
```

   f. On DC2 apply the file `custom-certs-external-dc2.yaml`:

```
kubectl -n <namespace> apply -f custom-certs-external-dc2.yaml
```

   g. Use the following commands to test that they are the same, on DC1 run:

```
kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/ingress.pem.dc1
```

   h. On DC2 run:

```
kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/ingress.pem.dc2
```

   i. To see the differences run:

```
diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
```

   The files should be the same.
   j. To verify that the certificates are working correctly and that they are using the `ingress-ca` secret, get the `portal-admin-client crt` file:

```
kubectl -n <namespace> get secrets portal-admin-client -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
/tmp/admin-client.crt
```

   k. Use OpenSSL to verify the certificate:

```
openssl verify -verbose -CAfile /tmp/ingress.pem.dc1 /tmp/admin-client.crt
```

   If it is valid, you should see:

```
/tmp/admin-client.crt: OK
```

What to do next

Configure your subsystem CR YAML files to use your custom certificates: Deploying API Connect subsystems with custom certificates.

Generating custom certificates manually

Generate custom certificates for API Connect without using cert-manager.

About this task

Note: If you want to customize only your user-facing endpoint certificates, then you do not need to configure them at installation. Install API Connect normally and then update the certificates following the steps in Customizing user-facing certificates.
If you choose to create your certificates manually, then you lose some of the management features of cert-manager. For example, you must manually update your certificates before they expire.

Requirements for manually created certificates:

- Extended Key Usage (EKU) must be either `serverAuth` or `clientAuth` depending upon the type of certificate. Certificates of the type *Server* must have an Extended Key Usage with `serverAuth` purpose. Certificates of the type *Client* must have an Extended Key Usage with `clientAuth` purpose.
- Subject Alternative Name (SAN) for the required hosts.
- If a certificate is signed by an internal or custom CA, include the full chain in the end certificate. If you omit the full chain, then a user who uses OpenSSL to access the endpoint gets the following error: `error:num=20:unable to get local issuer certificate`
  The following example shows the full chain for an end certificate (signed by a custom CA):

```
-------BEGIN CERTIFICATE -----
Cert contents for end-cert
--------END CERTIFICATE ----------
-------BEGIN CERTIFICATE -----
Cert contents for Intermediate-CA
```

```
--------END CERTIFICATE ----------
-------BEGIN CERTIFICATE -----
Cert contents for Root CA
--------END CERTIFICATE ----------
```

Procedure

1. Generate your custom certificates with the appropriate EKU and SAN. You must have the private key, public certificate, and CA certificates in non-password-protected PEM format. Following is an example for how to generate a certificate with an EKU **serverAuth** and SAN using OpenSSL:

   ```
   openssl x509 -req -days 360 -in platform-api-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
   platform-api-cert -sha256
   -extfile <(cat /etc/ssl/openssl.cf <(printf
   "\n[SAN]\nsubjectAltName=DNS:fqdn.myserver.com\nextendedKeyUsage=serverAuth"))
   -extensions SAN
   ```

   where
   - **DNS:fqdn.myserver.com** is the fully qualified domain name of the endpoint that the certificate applies to.
   - **platform-api-example.csr** is the file name for the certificate signing request.

   The following is an example for how to generate a certificate (portal-client) with an EKU **clientAuth** and SAN using OpenSSL:

   ```
   openssl x509 -req -days 360 -in portal-client-example.csr -CA root-ca.pem -CAkey root-ca-key.pem -CAcreateserial -out
   portal-client-cert
   -sha256 -extfile <(cat /etc/ssl/openssl.cnf <(printf "\n[SAN]\nkeyUsage=critical,
   digitalSignature,keyEncipherment\nextendedKeyUsage = clientAuth\nbasicConstraints=critical,
   CA:FALSE\nsubjectKeyIdentifier=hash\n")) -extensions SAN
   ```

   Note:
   When you prepare your custom certificates, certain pairs of certificates must be signed by the same certificate authority, as noted in the description of each certificate: API Connect TLS certificates.

   If you're installing a two data center disaster recovery configuration, and are using custom certificates, then the subject names of any client certificates must be the same in both data centers, as noted in the description of each certificate: API Connect TLS certificates. For example, the subject names in both data centers might both be **CN=portal-admin-client**, or they might both be **CN=ptl-adm-client, O=cert-manager**, but they must be identical.

2. Create a Kubernetes secret for each custom certificate.
   Create Kubernetes secrets for each of your custom certificates. The secrets must be of type **kubernetes.io/tls** and must contain the following **data** items: **ca.crt**, **tls.crt**, and **tls.key**.

   ```
   kubectl create secret generic my-tls-secret --from-file=tls.crt=<path_to_cert_file> --from-file=tls.key=<path_to_key_file>
   --from-file=ca.crt=<path_to_cacert_file>
   ```

   When you create each secret, it's helpful to reference its purpose or its corresponding certificate in the secret name, to ensure that you specify the correct secret for each custom certificate.

What to do next

Configure your subsystem CR YAML files to use your custom certificates: Deploying API Connect subsystems with custom certificates.

Deploying API Connect subsystems with custom certificates

Steps to configure API Connect subsystem CR YAML files to deploy them with custom certificates.

Before you begin

Create the custom certificates that you want to use, either creating the certificates manually or using cert-manager.
For a two data center disaster recovery deployment, follow the steps in Generating custom certificates using cert-manager in a two data center deployment.

About this task

This task covers the steps to configure your API Connect CR YAML files to use the custom certificates that you created.

Procedure

1. Edit the helper_files/ingress-issuer-v1.yaml file and delete the default definitions for the certificates that you are customizing.
   The ingress-issuer-v1.yaml file is provided as part of the installation **helper_files** archive. See Obtaining product files.

   This file is used for generating the default certificates. To use a custom certificate, you must delete the default definition so that API Connect uses your certificate instead of the default certificate. If you customize all the default certificates and delete those definitions from the file, then you don't need to use the file during installation.

2. Update the user-facing endpoint definitions in the subsystem CRs, for all the endpoints where you created a custom certificate.
   Note: If you want to customize only your user-facing endpoint certificates, then you do not need to customize them at installation. You can install API Connect normally and then update the certificates following the steps in Customizing user-facing certificates.
   For each custom endpoint certificate, delete the annotation that specifies the default issuer, and replace the secret name with your own custom secret name.

   a. Open the subsystem CR for editing and locate the endpoint definition.
      For example, the following snippet shows the definition for the **cloudManagerEndpoint** in the management CR:

```
  cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: admin.example.com
      secretName: cm-endpoint
```

b. Delete the annotation for the `cert-manager.io/issuer`.
Delete the field name and the value; you can leave the `annotations:` label in place.

c. Replace the default secret name with the name of the Kubernetes secret that you created for that endpoint's custom certificate.
In the following example, `cm-endpoint` is the default secret name, which must be replaced. Make sure to reference the correct secret for the custom certificate.

```
  cloudManagerEndpoint:
    annotations:
    hosts:
    - name: admin.example.com
      secretName: my_cm-endpoint
```

3. Customize internal (CA, inter, and intra-subsystem) certificates.
   a. Open the subsystem CR for editing.
   b. Set the `spec.microServiceSecurity` property to `custom`.
   By default, the setting is configured for `certManager` as shown in the following example:

```
microServiceSecurity: certManager
certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
```

   c. Delete the `spec.certManagerIssuer` block.
   In the following example, `microServiceSecurity` is set to `custom` and the `certManagerIssuer` block is commented out:

```
microServiceSecurity: custom
#certManagerIssuer:
#    name: selfsigning-issuer
#    kind: Issuer
```

4. Add the `spec.customCertificates` block and list the secret name for each internal custom certificate that you created for the subsystem.
   See the Table 5 table for the certificate names.

   You do not have to provide a custom certificate for every certificate supported by the subsystem. Put the custom certificates that you created; any certificates that you omit from the list are generated automatically during installation.

   For example, your `customCertificates` list for the management subsystem might look like the following:

```
customCertificates:
   - name: caCertificate
     secretName: management-ca
   - name: clientCertificate
     secretName: management-client
   - name: serverCertificate
     secretName: management-server
   - name: dbServerCertificate
     secretName: db-server-certificate
   - name: NATSTLSCertificate
     secretName: management-natscluster-mgmt
   - name: dbClientPostgres
     secretName: db-client-postgres
   - name: dbClientReplicator
     secretName: db-client-replication
   - name: dbClientApicuser
     secretName: db-client-apicuser
   - name: S3ProxyTLSCertificate
     secretName: management-s3proxy-all
```

What to do next

Complete the installation of API Connect:

- If you did not deploy the API Connect operator yet, proceed to Deploying operators in a single-namespace API Connect cluster or Deploying operators in a multi-namespace API Connect cluster.
- If you already deployed the operator, proceed to Installing the API Connect subsystems.

Installing the API Connect subsystems

Deploy the API Connect subsystem custom resources.

Before you begin

Attention: API Connect is not supported on a FIPS-enabled environment.
Before you install the subsystems, verify that you completed the following prerequisite tasks:

1. Obtaining product files
2. Deploying operators and cert-manager

About this task

Use the CR (custom resource) files to install the Management, Gateway, Analytics, and Portal subsystems for your API Connect cloud. CRs are extensions of the Kubernetes API. API Connect installs its subsystems using individual CRs. One CR is deployed per one managed subsystem. The API Connect operator manages the lifecycle of the subsystem CRs and deploys and manages the microservice for each one.

CR templates are provided in the **helper_files** archive to install each API Connect subsystem. You uncompressed these files into an installation folder of your choosing in Obtaining product files.

- The API Connect operators and operands must be at compatible versions of API Connect.
- You can deploy multiple instances of API Connect into the same cluster by using different namespaces.
- Deploying multiple similar subsystems in a single namespace is not supported. For example, deploying two management subsystems, **mgmt1**, **mgmt2** in a single namespace where API Connect operator is installed.
- For more information on Custom Resources in Kubernetes see https://kubernetes.io/docs/concepts/extend-kubernetes/api-extension/custom-resources/.
- For details on how the API Connect operator manages the CRs using the Kubernetes operator pattern, see https://kubernetes.io/docs/concepts/extend-kubernetes/operator/.
- For guidance on choosing object names and IDs in Kubernetes, see https://kubernetes.io/docs/concepts/overview/working-with-objects/names/#names.

Procedure

Complete each of the following instructions:

1. Installing the management subsystem.
2. Installing the gateway subsystem.
3. Installing the developer portal subsystem.
4. Installing the analytics subsystem.
5. When all subsystems are running, verify you can access the API Connect Cloud Manager. Enter the Cloud Manager endpoint URL in your browser.
   Tip:
   You can find your Cloud Manager endpoint URL as follows:

   The property **cloudManagerEndpoint** is specified in the management CR (**management_cr.yaml**). When you edited the template, you specified a value for ***$STACK_HOST***:

   ```
   cloudManagerEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: admin.$STACK_HOST
         secret: cm-endpoint
   ```

   The template URL is **https://admin.<*STACK_HOST*>/admin**. The **/admin** suffix at the end is the name of the Cloud Manager administrator.

   For example, if ***$STACK_HOST*** is **myhost.subnet.example.com**, the Cloud Manager endpoint URL is:

   ```
   https://admin.myhost.subnet.example.com/admin
   ```

   The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. See Accessing the Cloud Manager user interface.

What to do next

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

- **Installing the management subsystem**
  Install the management subsystem in your Kubernetes environment.
- **Installing the gateway subsystem**
  Install the DataPower gateway subsystem
- **Installing the developer portal subsystem**
  Install the developer portal subsystem.
- **Installing the analytics subsystem**
  Install the API Connect analytics subsystem.

Installing the management subsystem

Install the management subsystem in your Kubernetes environment.

Before you begin

Before you start this task, you should have already:

- Reviewed the Kubernetes requirements in Pre-installation requirements
- Completed Deploying operators and cert-manager

About this task

Edit the custom resource template for the management system, apply the resource, verify that the pods are up and running, and verify that you can connect to the API Connect Cloud Manager.

Procedure

1. Edit the `management_cr` template CR, to replace the placeholders with values for your deployment.

   `$APP_PRODUCT_VERSION`
   API Connect application version for the subsystems.

   ```
   version: <version_number>
   ```

   Example version number: 10.0.8.2-ifix1

   `$SECRET_NAME`
   Use for image pull.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

   `$PROFILE`
   Specify your management subsystem profile, where **`n`** indicates number of replicas, **`c`** number of cores, and **`m`** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

   `$DOCKER_REGISTRY`
   The host name of the Docker Registry to which you uploaded the installation images. For example:

   ```
   my.docker.registry.domain.example.com.
   ```

   $INGRESS_CLASS
   The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **`ingressclass.kubernetes.io/is-default-class:`** **`true`** is used. If such an ingress class does not exist in the Kubernetes environment, then **`nginx`** is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system.
   Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

   `$STACK_HOST`
   The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

   - Subdomain customization only
     Accept the prefixes predefined for the ingress host names to use and just replace all instances of **`STACK_HOST`** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **`myhost.subnet.example.com`**:

     ```
     cloudManagerEndpoint:
           < ... >
       hosts:
       - name: admin.myhost.subnet.example.com
         secret: cm-endpoint

     apiManagerEndpoint:
           < ... >
       hosts:
       - name: manager.myhost.subnet.example.com
         secret: apim-endpoint

     platformAPIEndpoint:
           < ... >
       hosts:
       - name: api.myhost.subnet.example.com
         secret: api-endpoint

     consumerAPIEndpoint:
           < ... >
       hosts:
       - name: consumer.myhost.subnet.example.com
         secret: consumer-endpoint

     consumerCatalogEndpoint:
           < ... >
       hosts:
       - name: consumer-catalog.myhost.subnet.example.com
         secret: consumer-catalog-endpoint
     ```

   - Complete hostname customization
     Change both the predefined prefixes and the **`STACK_HOST`** subdomain to match your desired hostnames.

     For example, for **`cloudManagerEndpoint`**, you can replace **`admin.$STACK_HOST`** with **`my.cloudmgr.myhost.subnet.example.com`**, where **`my.cloudmgr`** replaces **`admin`**, and **`myhost.subnet.example.com`** replaces **`STACK_HOST`**. For example:

     ```
     cloudManagerEndpoint:
           < ... >
       hosts:
       - name: my.cloudmgr.myhost.subnet.example.com
         secret: cm-endpoint
     ```

     You can do this for some or all of the host names, depending on your customization requirements.

   `$STORAGE_CLASS`
   The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **`kubectl get sc`**.

```
storageClassName: local-storage
```

2. Edit the `license:` setting:
   a. Set `accept:` to `true` to accept the license. Note that the default value is `false`. If you do not accept the license, the Operator will not install the subsystem.
   b. Set `metric:` to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.

   c. Set `use:` to either `production` or `nonproduction`, to match the license you purchased.
   d. Set `license:` to the License ID for the version of API Connect that you purchased. See API Connect licenses.

   Example entry to accept the license for a production system:

```
  license:
    accept: true
    metric: PROCESSOR_VALUE_UNIT
    use: production
    license: L-RJON-BZ5LSE
```

3. If installing with custom internal certificates, specify a site name.
   - The site name is used as the identifier for the PostgreSQL database cluster used by API Connect. This name should already have been decided upon and used to update the `custom-certs-internal.yaml` file as described in Generating custom certificates using cert-manager.
   - You must now add your chosen site name to `management_cr.yaml`, by creating a `siteName` property anywhere inside the `spec` block, set to the chosen site name:

     ```
       siteName: <site_name>
     ```

     Replace <*site_name*> with your chosen site name.

4. It is recommended to allocate 100Gi for write-ahead logging (WAL) storage.
   The default storage is:

   - One replica profile - 30Gi
   - Three replica profile - 47Gi

   For best performance, edit the CR to add the following entries, and set `volumeSize:` to 100Gi:

```
spec:
  dbArchiveVolumeClaimTemplate:
    storageClassName: <storage-class>
    volumeSize: <volume-size>
```

5. Optional: If you are installing as part of a two data center disaster recovery set up, complete the steps in Installing a two data center deployment on Kubernetes before you apply the edited file.
6. Install the management Custom Resource, replacing `<namespace>` with the target installation namespace in the Kubernetes cluster.

```
kubectl apply -f management_cr.yaml -n <namespace>
```

7. Verify that the management subsystem is fully installed:

```
kubectl get ManagementCluster -n <namespace>
```

   The installation has completed when the `READY` status is `True`, and the `SUMMARY` reports that all services are online (e.g. `9/9`). For example:

```
NAME          READY   SUMMARY    VERSION     RECONCILED VERSION    AGE
management    True    16/16       <version>    <version-build>       7m17s
```

8. Check your connection to the Cloud Manager user interface on the management subsystem on your Cloud Manager endpoint.
   For example, if you accepted the default prefix of `admin`, and you set `$STACK_HOST` to `myhost.subnet.example.com`, the Cloud Manager endpoint URL is:

```
https://admin.myhost.subnet.example.com/admin
```

   The first time that you access the Cloud Manager user interface, you enter `admin` for the user name and `7iron-hide` for the password. You will be prompted to change the Cloud Administrator password and email address. For further details, see Accessing the Cloud Manager user interface.

9. Backup your management subsystem database and infrastructure configuration: Backing up and restoring the management subsystem.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Installing the gateway subsystem

Install the DataPower gateway subsystem

Before you begin

Important: When you install the gateway subsystem, you must configure the gateway subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
If you plan to install the gateway subsystem in a remote cluster, be sure to satisfy the following requirements:

- Install both the API Connect and the DataPower operators.
  The versions of the operators on the remote cluster and the version of the gateway operand must exactly match the versions used in the main cluster.
- Make sure the remote cluster has the certificates:
  - If you are using certificate manager, ensure that the ingress-ca is synced between sites.
  - If you are not using certificate manager, copy the client gateway certificates to the remote cluster and reference them in the gateway CR.

About this task

Note: An alternate deployment scenario is to use a physical DataPower appliance for the gateway. If you are using an appliance for the gateway, do not install using API Connect Kubernetes CRs, since you do not need to configure a gateway subsystem in your Kubernetes cluster when using an appliance. For an appliance-based gateway, you must configure two endpoints in DataPower to be used as the Gateway Service Management Endpoint and the API invocation Endpoint. Enter these endpoints in the Configure Gateway Service screen in Cloud Manager. See Configuring DataPower Gateway for API Connect for instructions for configuring a DataPower appliance.
The installation folder where the **helper_files.zip** was extracted contains two templates for gateway service. The **v5cgateway_cr.yaml** template is for the v5 compatible gateway, and the **apigateway_cr.yaml** template is for the API Gateway.

Procedure

1. Edit the template CR, either **apigateway_cr.yaml** or **v5cgateway_cr.yaml**, to replace the placeholders with values for your deployment.

   $APP_PRODUCT_VERSION
   API Connect application version for the subsystems.

   ```
   version: <version_number>
   ```

   Example version number: 10.0.8.2-ifix1

   $PROFILE
   Specify your gateway profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

   $SECRET_NAME
   Use for image pull.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

   $DOCKER_REGISTRY
   The host name of the Docker Registry to which you uploaded the installation images. For example:

   ```
   my.docker.registry.domain.example.com.
   ```

   $INGRESS_CLASS
   The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **ingressclass.kubernetes.io/is-default-class: true** is used. If such an ingress class does not exist in the Kubernetes environment, then **nginx** is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system.
   Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

   $STACK_HOST
   The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:
   - Subdomain customization only
     Accept the prefixes predefined for the ingress hostnames to use and just replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

     ```
     gatewayEndpoint:
         < ... >
       hosts:
       - name: rgw.myhost.subnet.example.com
         secret: gwv6-endpoint

     gatewayManagerEndpoint:
         < ... >
       hosts:
       - name: rgwd.myhost.subnet.example.com
         secret: gwv6-manager-endpoint
     ```

   - Complete hostname customization
     Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

     For example, for **gatewayEndpoint**, you can replace **rgw.$STACK_HOST** with **my.gateway.endpoint.myhost.subnet.example.com**, where **my.gateway.endpoint** replaces **rgw**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

     ```
     gatewayEndpoint:
           < ... >
       hosts:
       - name: my.gateway.endpoint.myhost.subnet.example.com
         secret: gwv6-endpoint
     ```

     You can do this for some or all of the hostnames, depending on your customization requirements.

   $STORAGE_CLASS
   The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **kubectl get sc**.

```
storageClassName: local-storage
```

$ADMIN_USER_SECRET
Edit **$ADMIN_USER_SECRET** to set the value you created in Deploying operators and cert-manager.

```
adminUserSecret: $ADMIN_USER_SECRET
```

$PLATFORM_CA_SECRET
Set to **ingress-ca**. The **$PLATFORM_CA_SECRET** contains the CA certificate for the platform REST API endpoint. The gateway makes calls to the platform REST API and this property must be set so that the gateway can verify the server certificate.

```
mgmtPlatformEndpointCASecret:
  secretName: $PLATFORM_CA_SECRET
```

2. Edit the **license:** setting:
   a. Set **accept:** to **true** to accept the license. Note that the default value is **false**. If you do not accept the license, the Operator will not install the subsystem.
   b. Set **metric:** to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.

   c. Set **use:** to either **production** or **nonproduction**, to match the license you purchased.
   d. Set **license:** to the License ID for the version of API Connect that you purchased. See API Connect licenses.

   Example entry to accept the license for a production system:

```
  license:
    accept: true
    metric: PROCESSOR_VALUE_UNIT
    use: production
    license: L-RJON-BZ5LSE
```

3. Enable or disable **syslogConfig**.

```
syslogConfig:
    enabled: false # if true, provide below details
    # remoteHost: $DATAPOWER_SYSLOG_TCP_REMOTE_HOST # must be a string
    # remotePort: $DATAPOWER_SYSLOG_TCP_REMOTE_PORT # must be an int
    # secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

   - To disable syslog, remove the **syslogConfig** block from **apigateway_cr.yaml** and **v5cgateway_cr.yaml**. Alternatively, you can set **syslogConfig.enabled** to **false**.
   - To enable **syslogConfig** in the gateways, set the following values in **apigateway_cr.yaml** and **v5cgateway_cr.yaml**:

     enabled
     enabled: true
     $DATAPOWER_SYSLOG_TCP_REMOTE_HOST
     remoteHost: <*remote.host*>
     String. The hostname of the server for **syslogConfig**.

     $DATAPOWER_SYSLOG_TCP_REMOTE_PORT
     remotePort: <*remote_port_number*>
     Integer. The port number of the server for **syslogConfig**.

     $DATAPOWER_SYSLOG_TCP_TLS_SECRET
     secretName: <*secret*>
     String. The TLS secret name of the server for **syslogConfig**.

4. Optional: If applicable to your deployment, update the GatewayCluster CR to configure **DataPowerService** APIs to customize your DataPower deployment. See Customizing a DataPower deployment.
5. Enable mutual TLS between the management client and the gateway service's manager endpoint, add **mtlsValidateClient** to the **spec** section:
   Important: Do not skip this step, if you do not want to use mTLS for management to gateway communication, then you can enable JWT instead.

```
spec:
  mtlsValidateClient: true
```

   This ensures that the gateway service authenticates incoming requests from the API Manager, such as gateway service registration, and publishing APIs to the gateway service. Specifically, the gateway service requires that incoming requests present a certificate that was signed by the same CA that was used to sign the gateway service management endpoint. The gateway service management endpoint secret is specified under **gatewayManagerEndpoint.hosts.secretName**. The API Manager's gateway client's TLS credentials are specified in the ManagementCluster CR under **gateway.client.secretName**.

6. Optional: If you want to enable JWT security for communications between the management and gateway, add and set the property **jwksUrl**, and set **spec.mtlsValidateClient** to false.

```
spec:
  ...
  jwksUrl: <JWKS URL>
  mtlsValidateClient: false
```

   where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

   For more information about JWT security, see Enable JWT security instead of mTLS.

7. Optional: If you want to use the In-cluster inter-subsystem communication feature, then uncomment the `mgmtPlatformEndpointSvcCASecret` section, and set the `secretName`:

   ```
   mgmtPlatformEndpointSvcCASecret:
     secretName: management-ca  # Usually management-ca
   ```

   Unless you customized your internal certificates, this is always `management-ca`.
8. Optional: Enable autoscaling of gateway pods to ensure high availability of DataPower pods. See Enabling autoscaling of gateway pods.
9. Install the gateway Custom Resource by applying the gateway template file:
   For a DataPower API Gateway, run the following command:

   ```
   kubectl apply -f apigateway_cr.yaml -n <namespace>
   ```

   For a DataPower Gateway (v5 compatible), run the following command:

   ```
   kubectl apply -f v5cgateway_cr.yaml -n <namespace>
   ```

10. To verify that the gateway subsystem(s) are fully installed, run the following command:

    ```
    kubectl get GatewayCluster -n <namespace>
    ```

    The installation has completed when the `READY` status is `True`, and the `SUMMARY` reports that all services are online (`2/2`) for all the gateway subsystems that were installed. Example:

    ```
    NAME   READY   SUMMARY   VERSION     RECONCILED VERSION    AGE
    gwv5   True    2/2       <version>   <version-build>       7m31s
    gwv6   True    2/2       <version>   <version-build>       7m32s
    ```

    There is no need to wait for the `READY` status to be `True` before moving on to the next Subsystem installation.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Installing the developer portal subsystem

Install the developer portal subsystem.

About this task

Important: When you install the portal subsystem, you must configure the portal subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Important:

- To enable effective high availability for your portal service, you need a latency that is less than 50 ms between all portal-db pods to avoid the risk of performance degradation. Servers with uniform specifications are required, as any write actions occur at the speed of the slowest portal-db pod, as the write actions are synchronous across the cluster of portal-db pods. It is recommended that there are three servers in each cluster of portal-db pods for the high availability configuration. The three servers can be situated in the same availability zone, or across three availability zones to ensure the best availability. However, you can configure high availability with two availability zones.
- The portal does not do certain operations if the free space on certain volumes falls beneath predefined limits. In particular:
  The `databaseVolumeClaimTemplate` needs at least 4GB of free space to create new sites, restore site backups, or upgrade or change the URL of existing sites.

  The `webVolumeClaimTemplate` needs at least 256MB free space to create new sites, restore site backups, or upgrade or change the URL of existing sites.

- Ensure that your kernel or Kubernetes node has the value of its `inotify` watches set high enough so that the Developer Portal can monitor and maintain the files for each Developer Portal site. If set too low, the Developer Portal containers might fail to start or go into a `non-ready` state when this limit is reached. If you have many Developer Portal sites, or if your sites contain a lot of content, for example, many custom modules and themes, then a larger number of `inotify` watches are required. You can start with a value of 65,000, but for large deployments, this value might need to go up as high as 1,000,000. The Developer Portal containers take `inotify` watches only when they need them. The full number is not reserved or held, so it is acceptable to set this value high.
- Ensure that your kernel or Kubernetes node has a value of `nproc` (maximum number of processes) that applies to the user ID of the portal pods that have been assigned, and that it is high enough to allow all of the portal processes to execute. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls, you might need as many as 125205. If the number is too low, you will see errors like `"fork: retry: Resource temporarily unavailable"` in the portal logs. Note that this value might need to be even higher if other, non-portal, pods are sharing the same user ID.
- Ensure that your kernel or Kubernetes node has a value of `nofiles` (maximum number of open file descriptors) that applies to the user ID of the portal pods that have been assigned, and that it is high enough to allow the portal to open all of the files that it requires. For smaller installations this might be as low as 16384, but for larger installations that have more concurrent web calls and portal web sites, you might need as many as 1048576. If the number is too low, you will see errors like `"too many open files"` in the portal logs. Note that this value might need to be even higher if other, non-portal, pods are sharing the same user ID.

The portal endpoints values are used when you configure a portal service in the Cloud Manager. See Registering a Portal service.

- `portalAdminEndpoint` - This is the Management Endpoint that is defined in Cloud Manager, which is used for communicating with API Manager.
- `portalUIEndpoint` - This is the portal website URL defined in Cloud Manager. It determines the URL for the site that is created for each catalog. It is used for public access to the portal from a browser.

Important: The endpoints defined here must be the ones used by the Management subsystem when registering the portal, and portal users when accessing portal sites. Do not attempt to proxy these endpoints. You will not be able to register the portal service nor access portal sites using any other endpoint URLs than those defined here.

Procedure

1. Edit the `portal_cr` template CR to replace the placeholders with values for your deployment.

   `$APP_PRODUCT_VERSION`
   API Connect application version for the subsystems.

   ```
   version: <version_number>
   ```

   Example version number: 10.0.8.2-ifix1

   `$PROFILE`
   Specify your portal subsystem profile, where **`n`** indicates number of replicas, **`c`** number of cores, and **`m`** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

   `$SECRET_NAME`
   Use for image pull.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

   `$DOCKER_REGISTRY`
   The host name of the Docker Registry to which you uploaded the installation images. For example:

   ```
   my.docker.registry.domain.example.com.
   ```

   $INGRESS_CLASS
   The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation **`ingressclass.kubernetes.io/is-default-class:`** **`true`** is used. If such an ingress class does not exist in the Kubernetes environment, then **`nginx`** is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system.
   Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

   `$STACK_HOST`
   The desired ingress subdomain for the API Connect stack. Used when you specify endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

   - Subdomain customization only
     Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **`STACK_HOST`** to be the desired ingress subdomain for the API Connect stack. For example, for a subdomain of **`myhost.subnet.example.com`**:

     ```
     portalAdminEndpoint:
         < ... >
         hosts:
         - name: api.portal.myhost.subnet.example.com
           secret: portal-admin

       portalUIEndpoint:
         < ... >
         hosts:
         - name: portal.myhost.subnet.example.com
           secret: portal-web
     ```

   - Complete hostname customization
     Change both the predefined prefixes and the **`$STACK_HOST`** subdomain to match your desired hostnames.

     For example, for **`portalAdminEndpoint`**, you can replace **`api.portal.$STACK_HOST`** with **`my.api.portal.myhost.subnet.example.com`**, where **`my.api.portal`** replaces **`api.portal`**, and **`myhost.subnet.example.com`** replaces **`$STACK_HOST`**:

     ```
     portalAdminEndpoint:
           < ... >
         hosts:
         - name: my.api.portal.myhost.subnet.example.com
           secret: cm-endpoint
     ```

     You can do this for some or all of the hostnames, depending on your customization requirements.

   `$STORAGE_CLASS`
   The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **`kubectl get sc`**. For example, for local storage:

   ```
   databaseVolumeClaimTemplate:
       storageClassName: $STORAGE_CLASS
       volumeSize: 200Gi
   databaseLogsVolumeClaimTemplate:
       storageClassName: $STORAGE_CLASS
       volumeSize: 12Gi
   webVolumeClaimTemplate:
       storageClassName: $STORAGE_CLASS
       volumeSize: 200Gi
   backupVolumeClaimTemplate:
       storageClassName: $STORAGE_CLASS
       volumeSize: 120Gi
   adminVolumeClaimTemplate:
       storageClassName: $STORAGE_CLASS
       volumeSize: 20Gi
   certVolumeClaimTemplate:
       storageClassName: $STORAGE_CLASS
       volumeSize: 4Gi
   ```

   `$PLATFORM_CA_SECRET`

Set to **ingress-ca**. The **$PLATFORM_CA_SECRET** contains the CA certificate for the platform REST API endpoint. The portal makes calls to the platform REST API and this property must be set so that the portal can verify the server certificate.

```
mgmtPlatformEndpointCASecret:
  secretName: $PLATFORM_CA_SECRET
```

$CONSUMER_CA_SECRET
Set to **ingress-ca**. The **$CONSUMER_CA_SECRET** contains the CA certificate for the consumer REST API endpoint. The portal makes calls to the consumer REST API and this property must be set so that the portal can verify the server certificate.

```
mgmtConsumerEndpointCASecret:
  secretName: $CONSUMER_CA_SECRET
```

Note:

- The **databaseVolumeClaimTemplate** has a minimum value of 30Gi. The **webVolumeClaimTemplate** has a minimum value of 20Gi. The **backupVolumeClaimTemplate** has a minimum value of 30Gi. However, all three need to be sized according to the installation. For more information on planning your portal PV requirements, see Portal subsystem.
- The **adminVolumeClaimTemplate** and **databaseLogsVolumeClaimTemplate** in this example have their minimum values and you do not need to change them.
- The **certVolumeClaimTemplate** is used by the nginx pod and in 2DCDR mode it is also by the **tunnel**, **db-remote** and **www-remote** pods. It can be sized small, just like the **adminVolumeClaimTemplate**, and does not need to be increased based on the number of sites.

2. Edit the **license:** setting:
   a. Set **accept:** to **true** to accept the license. Note that the default value is **false**. If you do not accept the license, the Operator will not install the subsystem.
   b. Set **metric:** to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.

   c. Set **use:** to either **production** or **nonproduction**, to match the license you purchased.
   d. Set **license:** to the License ID for the version of API Connect that you purchased. See API Connect licenses.

   Example entry to accept the license for a production system:

```
  license:
    accept: true
    metric: PROCESSOR_VALUE_UNIT
    use: production
    license: L-RJON-BZ5LSE
```

3. Optional: If you want to disable mTLS for communications between the management and portal, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

   where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

   For more information about JWT security, see Enable JWT security instead of mTLS.
4. Optional: If you want to use the In-cluster inter-subsystem communication feature, then uncomment the **mgmtPlatformEndpointSvcCASecret** and the **mgmtConsumerEndpointSvcCASecret** sections, and set the **secretName** for both:

```
  mgmtPlatformEndpointSvcCASecret:
    secretName: management-ca  # Usually management-ca
  mgmtConsumerEndpointSvcCASecret:
    secretName: management-ca  # Usually management-ca
```

   Unless you customized your internal certificates, these secrets are always **management-ca**.
5. Optional: If you are installing as part of a two data center disaster recovery set up, complete the steps in Installing a two data center deployment on Kubernetes before you apply the edited file.
6. Install the portal Custom Resource, replacing **<namespace>** with the target installation namespace in the Kubernetes cluster:

```
kubectl apply -f portal_cr.yaml -n <namespace>
```

7. Verify that the portal subsystem is fully installed:

```
kubectl get PortalCluster -n <namespace>
```

   The installation is complete when **STATUS** reports **Running**, **Ready** reports that all services are online (**3/3**), and **MESSAGE** reports "Ready for API Cloud Manager service registration", for example:

```
NAME           READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                    AGE
portal         3/3     Running   <version>  <version>            Ready for API Cloud Manager service registration   2h
```

   You do not need to wait for the portal installation to complete before you move on to the next subsystem installation.
8. We highly recommend that you retain the portal subsystem encryption secret in a safe location, in case you need to restore the portal subsystem during a disaster recovery scenario.
   The encryption secret is created when the portal subsystem is initially deployed. You can obtain the name of the encryption secret from the portal subsystem custom resource once the installation is complete. For example:

   a. Obtain the name of the encryptionSecret:

```
kubectl get ptl portal -o yaml | grep encryptionSecret
encryptionSecret: portal-enc-key
```

The name of encryption secret is **portal-enc-key**.

b. Save the secret yaml in a safe location:

```
kubectl get secret portal-enc-key -o yaml > portal-enc-key.yaml
```

9. Backup the portal installation. See Backing up and restoring the developer portal.
Note:
When you create or register a Developer Portal service, the portal subsystem checks that the portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the **portal-www** pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the portal web endpoint check so that the Developer Portal service can be created successfully.
To disable the endpoint check, complete the following update:

On Kubernetes, OpenShift, and IBM® Cloud Pak for Integration
Add the following section to the portal custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you completed the installation of all the required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

- **Defining multiple portal endpoints for a Kubernetes environment**
Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

Defining multiple portal endpoints for a Kubernetes environment

Multiple public facing endpoints (portal-www) can be defined for the Developer Portal.

About this task

You can override the single endpoint definition for portal-WWW, and the associated **portal-www-ingress** TLS certificate, to support multiple **portal-www** endpoints.

For information about the endpoints for the Developer Portal, see Installing the developer portal subsystem.

Following are the example endpoints for configuring different sites served by the same Developer Portal service, as configured in this task:

- https://banking.example.com/loans
- https://insurance.example.com/vehicle

These unique endpoints allow Developer Portal sites to be defined on the Developer Portal service with different host names and domains. They replace endpoints that distinguish different sites by sub paths, as shown in the following examples:

- https://www.example.com/banking/loans
- https://www.example.com/insurance/vehicle

Procedure

Edit your **portal_cr** template. You can add multiple entries for your endpoints in the **hosts** element:
For example:

```
spec:
    portalUIEndpoint:
        annotations:
          cert-manager.io/issuer: ingress-issuer
        hosts:
        - name: ptl.host1.example.com
          secretName: portal-web-host1
        - name: ptl.host2.example.com
          secretName: portal-web-host2
        - name: ptl.host3.example.com
          secretName: portal-web-host3
```

Installing the analytics subsystem

Install the API Connect analytics subsystem.

Review Planning your analytics deployment to ensure that you understand the choices for configuring the topology, disk space, and other elements of the analytics subsystem.

Note: When the analytics service is configured to store data, it uses OpenSearch, which requires map counts higher than the operating system defaults. The minimum recommended value is `262144`. If you plan to store analytics data locally (that is, do you not intend to disable local storage and offload all data), increase the default map count on every Kubernetes node:

1. To change the map counts on the live system, run the following command on every Kubernetes node:

   ```
   sudo sysctl -w vm.max_map_count=262144
   ```

2. To persist this change when node restarts occur, add the following setting to the /etc/sysctl.conf file:

   ```
   vm.max_map_count = 262144
   ```

For more information, see Important settings in the OpenSearch documentation.

- **Creating the analytics CR**
  Create the installation CR for API Connect analytics so that you can deploy the analytics subsystem.
- **Installing analytics**
  Deploy the analytics CR to install the analytics subsystem in your API Connect deployment.

Creating the analytics CR

Create the installation CR for API Connect analytics so that you can deploy the analytics subsystem.

Before you begin

Important: When you install the analytics subsystem, you must configure the analytics subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Review Analytics preinstallation planning to decide on your deployment options.

About this task

To install the analytics subsystem, define the analytics Custom Resource (CR) in a YAML file. The YAML file contains all of your configuration settings for the analytics deployment. Use the file to install, upgrade, and update the configuration of your analytics subsystem.
Note: The analytics_cr.yaml template file is stored in the directory where you extracted helper_files.zip.

Procedure

1. Create or copy the analytics_cr.yaml file from the helper_files.
2. Edit the CR file and update the following settings:
   You cannot install the analytics subsystem until the placeholders are replaced with real values for your environment.

   `$APP_PRODUCT_VERSION`
   API Connect application version for the subsystems.

   ```
   version: <version_number>
   ```

   Example version number: 10.0.8.2-ifix1

   `$PROFILE`
   Specify your analytics subsystem profile, where `n` indicates number of replicas, `c` number of cores, and `m` is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.
   Note: The profile that you select influences your storage type options. If you select an `n1` profile then you must select the `shared` storage type. For more information about storage types, see storage types.

   `$SECRET_NAME`
   The name of the secret used to pull images from the Docker registry.

   ```
   imagePullSecrets:
     - apic-registry-secret
   ```

   `$DOCKER_REGISTRY`
   The hostname of the Docker Registry to which you uploaded the installation images. For example:

   ```
   my.docker.registry.domain.example.com.
   ```

   $INGRESS_CLASS
   The ingress class that you want the endpoint to use. This property is optional and if not specified, the ingress class with annotation `ingressclass.kubernetes.io/is-default-class:`
   `true` is used. If such an ingress class does not exist in the Kubernetes environment, then `nginx` is used. If you do set this value, it must refer to a valid ingress class configured in your Kubernetes system.
   Note: This property is commented out in the template CR file. If you set this value, make sure to also uncomment it.

   `$STACK_HOST`

The ingress subdomain for the API Connect stack. Used for the ingestion endpoint. Domain names that are used for endpoints cannot contain the underscore "_" character. You can customize the subdomain or the complete hostname:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** with the ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
ingestion:
  endpoint:
     < ... >
    hosts:
    - name: ai.myhost.subnet.example.com
      secretName: analytics-ai-endpoint
     < .... >
```

$STORAGE_TYPE
If you selected an n1 (one replica) profile in **$PROFILE**, then set **$STORAGE_TYPE** to **shared**. If you selected an n3 (three replica) profile, then set **$STORAGE_TYPE** to **dedicated**. For more information about analytics storage types, see Storage type.

$STORAGE_CLASS
The Kubernetes storage class to be used for persistent volume claims. For more information, see Analytics preinstallation planning. Find the available storage classes in the target cluster by running the following command: **kubectl get sc**.

- For shared storage deployments (where you set **$STORAGE_TYPE** to **shared**):

```
storage:
  type: shared
  shared:
    volumeClaimTemplate:
      storageClassName: local_storage
```

- For dedicated storage deployments (where you set **$STORAGE_TYPE** to **dedicated**), set **$STORAGE_CLASS** in two places:

```
storage:
  type: dedicated
  shared:
    volumeClaimTemplate:
      storageClassName: local_storage
      ...
  master:
    volumeClaimTemplate:
      storageClassName: local_storage
      ...
```

$DATA_VOLUME_SIZE
Replace **$DATA_VOLUME_SIZE** with the value that you calculated in Estimating storage requirements. If you are unable to estimate your storage requirement then set it to 500Gi.

```
storage:
  ...
  shared:
    volumeClaimTemplate:
      ...
      volumeSize: 500Gi
```

3. Edit the **license** setting.
   a. Set **accept:** to **true** to accept the license. The default value is **false**. If you do not accept the license, the Operator does not install the subsystem.
   b. Set **metric:** to track your product usage. Enter the unit of measure that is used for your program license:
      - PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used.
      - MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.

      For information on tracking monthly call volume, see Counting total API calls.
   c. Set **use:** to either **production** or **nonproduction** to match the license you purchased.
   d. Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

Example entry to accept the license for a production system:

```
license:
  accept: true
  metric: PROCESSOR_VALUE_UNIT
  use: production
  license: L-RJON-CEBL97
```

4. Optional: If you want to disable mTLS for communications between the management and analytics subsystem, and between the gateway and analytics subsystem, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow.

5. Optional: If you plan to configure analytics database backups, then define the storage that is required for backups:
   Define your backup PVC by adding the `backup.volumeClaimTemplate` property in `spec.storage`. For example:

```
spec:
  storage:
    backup:
      volumeClaimTemplate:
        storageClassName: <storage class>
        volumeSize: <size>
```

   If you are not sure of the volume size that you need, then you can configure the `backup.volumeClaimTemplate` after installation.

6. Save the file.

What to do next

Install your analytics subsystem: Installing analytics.
Important: All analytics advanced configuration options can be added, changed, or removed after installation **except** for disablement or enablement of internal storage. If you want to disable internal storage, you must configure it in the analytics CR before installation: Disable local storage.

Installing analytics

Deploy the analytics CR to install the analytics subsystem in your API Connect deployment.

Before you begin

Now that you have a complete analytics CR file, double-check it for accuracy. In particular, verify that:

- No placeholder values remain in the analytics_cr.yaml file.
- You configured all the topology options that you plan to deploy.
- You configured appropriate volume size for storage.

Procedure

1. Run the following command to apply the analytics_cr.yaml:

   ```
   kubectl apply -f path/to/analytics-cr -n namespace
   ```

   where:
   - *path/to/analytics-cr* is the path to your saved analytics_cr.yaml file.
   - *namespace* is the name of your namespace.
2. Verify that the analytics subsystem is fully installed by running the following command:

   ```
   kubectl get AnalyticsCluster -n namespace
   ```

   where *namespace* is the name of your namespace.
   The installation is complete when the `READY` status is `True` and the `SUMMARY` reports that all services are online. Example:

   ```
   NAME        READY   SUMMARY   VERSION    RECONCILED VERSION   AGE
   analytics   True    5/5       <version>   <version-build>       7m39s
   ```

   The `SUMMARY` total count is based on your configured topology. Both numbers are equal when the installation is complete.

Results

Table 1 lists the pods that are expected in the three replica analytics deployment profile.

Table 1. Expected analytics subsystem pods

Expected	Pods	Note
3	director	Always expected.
3	ingestion	Always expected.
3	mtls-gw	Always expected.
3	storage	Not expected if you disabled internal storage.
3	storage-os-master	Not expected if you disabled internal storage. Not expected if shared storage is configured.
3	osinit	Expected to be in completed state.
1	data-warehouse	Expected if backups are enabled. For information about analytics database backups, see configure analytics database backups.

The one replica profile has 1 replica (instead of 3) of each pod.

What to do next

Take a backup of your analytics subsystem and configure scheduled analytics database backups: Analytics backup and restore.

Installing a two data center deployment on Kubernetes

Additional installation instructions for a two data center disaster recovery (2DCDR) deployment on Kubernetes.

Before you begin

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center warm-standby deployment on Kubernetes and OpenShift.

Download the operator files and custom resource definitions for use during installation onto both of your data centers. Ensure that you complete the instructions for Deploying operators and cert-manager, and set the same ingress-ca certificate in both data centers: Installing cert-manager and certificates in a two data center deployment.

Familiarize yourself with the instructions in Installing the API Connect subsystems. Follow these instructions along with the 2DCDR specific steps in this topic.

Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a 2DCDR deployment.
Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).

The following endpoints must be the same on both data centers:

Management subsystem endpoints

- `cloudManagerEndpoint`
- `apiManagerEndpoint`
- `platformAPIEndpoint`
- `consumerAPIEndpoint`
- `consumerCatalogEndpoint`

Portal subsystem endpoints

- `portalAdminEndpoint`
- `portalUIEndpoint`

For more information about how to set the endpoints, see Installing the management subsystem on Kubernetes, Installing the developer portal subsystem on Kubernetes.

About this task

A 2DCDR deployment differs from a standard API Connect deployment in that the custom resources (CRs) for both the management and portal in each data center include a **multiSiteHA** configuration section. The **multiSiteHA** section is used to define which data center is the active and which is the warm-standby.

The following examples show **multiSiteHA** sections in the **PortalCluster** CRs for the active and warm-standby data centers.

```
siteName: dallas
multiSiteHA:
  mode: active
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationdallas.cluster1.example.com
      secretName: dallas-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationraleigh.cluster2.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

```
siteName: raleigh
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationraleigh.cluster2.example.com
      secretName: raleigh-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

Table 1. **multiSiteHA** configuration properties

Configuration property	Description
`mode`	The state of the data center in the context of the 2DCDR deployment. Valid values are: • **active** - indicates the active data center. • **passive** - indicates the warm-standby data center.

`replicationEndpoint`
`  annotations:`
`  cert-manager.io/issuer:`
`ingress-issuer`
`  hosts:`
`  - name:`
`  secretName:`
	Contains details of the external ingress name for the subsystem in the current data center in the 2DCDR deployment.
	The hosts **name** is a unique fully qualified hostname that the other data center uses to communicate with the current data center.

`replicationPeerFQDN`	The ingress hostname for the other data center in the 2DCDR deployment. This information is required so that the two data centers can communicate with each other.
`tlsClient:` `  secretName`	The TLS client secret for the subsystem.

The **siteName** property is a unique descriptive name for the portal and management subsystems, in each data center. For example, **dallas** in data center 1 (DC1), and **raleigh** in data center 2 (DC2).

- Set a different **siteName** on the active to the one set on the warm-standby data center.
- **siteName** is used in the hostnames, and so can contain only **a-z** and **0-9** characters.
- You can set a **siteName** in the **ManagementCluster** or **PortalCluster** CRs only on installation. You cannot change the name after deployment. If you don't set a **siteName** at first deployment, an automated **siteName** is created for you.

To install a 2DCDR deployment:

1. Set the placeholder properties in the CR file for management and portal subsystems as detailed in Installing the API Connect subsystems, but do not run the final `kubectl apply` operation. Complete the additional 2DCDR configuration steps before you run `kubectl apply`.
2. Set the properties in the `multiSiteHA` section, and synchronize encryption secrets between the data centers as described in the procedure below:

Procedure

- **Installing to an active data center**
  The following example shows how to set the multi-site HA CR values for deploying to the active data center. In this example, the initial active data center is called `dallas` (DC1) and the warm-standby data center is called `raleigh` (DC2).

  1. Set Dallas to be active for the API Manager service on DC1.
     Edit the `ManagementCluster` CR file management_cr for DC1, and set the `multiSiteHA` properties as shown:

     ```
     siteName: dallas
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: mgrreplicationdallas.cluster1.example.com
           secretName: dc1-mgmt-replication
       replicationPeerFQDN: mgrreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: dc1-mgmt-replication-client
     ```

  2. Set Dallas to be active for the Developer Portal service on DC1.
     Edit the `PortalCluster` CR file portal_cr for DC1, and set the `multiSiteHA` properties as shown:

     ```
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: ptlreplicationdallas.cluster1.example.com
           secretName: dallas-ptl-replication-worker-1
       replicationPeerFQDN: ptlreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: ptl-replication-client
     ...
     siteName: dallas
     ```

  3. Create a secret called `ptl-encryption-key` on the active and warm-standby data centers.
     The secret must use the same random string in both data centers. Run the following command:

     ```
     kubectl create secret generic ptl-encryption-key --from-literal=encryption_secret=<RANDOM STRING> -n <namespace>
     ```

     The string can consist of uppercase letters, lowercase letters, and numbers, and must be at least 64 characters and no more than 100 characters.

  4. When the secrets are created on both DC1 and DC2, update the portal CR on DC1 and DC2 and add the following under the `spec` section:

     ```
     encryptionSecret:
       secretName: ptl-encryption-key
     ```

     Warning: Ensure that you add the secret directly under the `spec` section and not inside the `multiSiteHA` section.
  5. Create a secret called `mgmt-encryption-key` on the active and warm-standby data centers.
     The secret must use the same random string in both data centers. Run the following command:
     Note: Do not use the same random string that you used to create the secret for `ptl-encryption-key`.

     ```
     kubectl create secret generic mgmt-encryption-key --from-literal=encryption_secret.bin=<RANDOM STRING> -n <namespace>
     ```

     The string can consist of uppercase letters, lowercase letters, and numbers, and must be at least 64 characters and no more than 100 characters.

  6. When the secrets are created on both DC1 and DC2, update the portal CR on DC1 and DC2 and add the following under the `spec` section:

     ```
     encryptionSecret:
       secretName: mgmt-encryption-key
     ```

     Warning: Ensure that you add the secret directly under the `spec` section and not inside the `multiSiteHA` section.
  7. Apply the CR files to the subsystems in DC1.
     For example, to apply the `ManagementCluster` CR file to the DC1 cluster, run the following command:

     ```
     kubectl apply -f management_cr.yaml -n <namespace>
     ```

     Where `<namespace>` is the target installation namespace in the Kubernetes cluster for DC1. Repeat this process to apply the updated `PortalCluster` CR file to DC1.
     You can verify that the installation process is running with the following command:

     ```
     kubectl get ManagementCluster -n <namespace>
     ```

     Note: Until the warm-standby is installed and running, the `haStatus` reports `PeerNotReachable`.
     Change `ManagementCluster` to `PortalCluster` to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

  8. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

     Management subsystem endpoints
     - `cloudManagerEndpoint`

- `apiManagerEndpoint`
- `platformAPIEndpoint`
- `consumerAPIEndpoint`
- `consumerCatalogEndpoint`

Portal subsystem endpoints

- `portalAdminEndpoint`
- `portalUIEndpoint`

- **Installing the warm-standby data center**
  The following example shows how to set the multi-site HA CR values for the remote data center called `raleigh` (DC2) to be the warm-standby. Use the same encryption key on both sites.

  Ensure that the installation of the active data center is complete before you start the installation of the warm-standby data center.

  1. Set Raleigh to be warm-standby for the API Manager service on DC2.
     Edit the `ManagementCluster` CR file management_cr for DC2, and set the `multiSiteHA` properties as shown:

     ```
     multiSiteHA:
       mode: passive
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: mgrreplicationraleigh.cluster2.example.com
           secretName: raleigh-mgr-replication-worker-1
       replicationPeerFQDN: mgrreplicationdallas.cluster1.example.com
       tlsClient:
         secretName: mgr-replication-client
     ...
     siteName: raleigh
     ```

  2. Set Raleigh to be warm-standby for the Developer Portal service on DC2.
     Edit the `PortalCluster` CR file portal_cr for DC2, and set the `multiSiteHA` properties as shown:

     ```
     multiSiteHA:
       mode: passive
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: ptlreplicationraleigh.cluster2.example.com
           secretName: raleigh-ptl-replication-worker-1
       replicationPeerFQDN: ptlreplicationdallas.cluster1.example.com
       tlsClient:
         secretName: ptl-replication-client
     ...
     siteName: raleigh
     ```

  3. Apply the CR files to the subsystems in DC2.
     For example, to apply the `ManagementCluster` CR file to the DC2 cluster, run the following command:

     ```
     kubectl apply -f management_cr.yaml -n <namespace>
     ```

     Where *<namespace>* is the target installation namespace in the Kubernetes cluster for DC2. Repeat this process to apply the updated `PortalCluster` CR file to DC2.
     You can verify that the installation process is running with the following command:

     ```
     kubectl get ManagementCluster -n <namespace>
     ```

     When installation is complete, `haStatus` reports `Ready`.
     Change *`ManagementCluster`* to *`PortalCluster`* to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

- **Validating your two data center deployment**
  While the management subsystems on the warm-standby and active data centers are synchronizing their databases, the management status reports `Warning`, and the `haStatus` reports `pending`:

  ```
  kubectl get mgmt -n <namespace>
  ```

  ```
  NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
  AGE
  management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in
  CR for details   8m59s
  ```

  ```
  status:
    haStatus
      {
        "lastTransitionTime": "2023-03-31T19:47:08Z",
        "message": "Replication not working, install or upgrade in progress.",
        "reason": "na",
        "status": "True",
        "type": "Pending"
     }
  ```

  When the management database replication between sites is complete, the management status reports `Running`, and `status.haStatus` reports `Ready`:

  ```
  oc get mgmt -n <namespace>
  ```

  ```
  NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
  AGE
  management    n/n     Running   10.0.8.0-0   10.0.8.0-0           Management is ready. HA status Ready - see HAStatus in CR
  for details              8m59s
  ```

```
oc get mgmt -n <namespace> -o yaml

...
status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

If the management database replication between sites fails for any reason other than because an install or upgrade is in progress, the `haStatus` output shows the reason, for example::

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in
CR for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "PeerNotReachable"
   }
```

If the warning persists, see Troubleshooting a two data center deployment.
You can validate that your portal deployments are synchronizing by running **`kubectl get pods`** on both the active and warm-standby data centers, and confirming that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the **`Ready`** state.

For additional replication verification checks, see Verifying replication between data centers. It is recommended to run a test failover, and confirm that all of the expected data is present and correct on the newly active site. See Failing over to the warm-standby.

- **Converting a single data center to a two data center deployment on Kubernetes**
  Instructions on how to convert a single data center to a two data center disaster recovery (2DCDR) deployment on Kubernetes.

Related concepts

- Maintaining a two data center deployment

Converting a single data center to a two data center deployment on Kubernetes

Instructions on how to convert a single data center to a two data center disaster recovery (2DCDR) deployment on Kubernetes.

Before you begin

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center warm-standby deployment on Kubernetes and OpenShift.

Download the operator files and custom resource definitions for use during installation onto both of your data centers. Ensure that you complete the instructions for Deploying operators and cert-manager, and set the same ingress-ca certificate in both data centers: Installing cert-manager and certificates in a two data center deployment.

Familiarize yourself with the instructions in Installing the API Connect subsystems. Follow these instructions along with the 2DCDR specific steps in this topic.

Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a 2DCDR deployment.
Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).

About this task

You can convert a single data center API Connect to a 2DCDR deployment. Both data centers must have the same **`portal-admin`** and **`portal-www`** endpoints. The main difference is that the custom resource (CR) files for both the Management subsystem and the Developer Portal subsystem on each data center must include a **`multiSiteHA`** configuration section, and it's this section that determines the two data center DR deployment. It's also this section that's used to control the deployment in the future, for example in failover and recovery situations.

The following codeblocks show examples of completed **`multiSiteHA`** sections in the **`PortalCluster`** CR files for two data centers, one active and one warm-standby. Both the **`ManagementCluster`** and the **`PortalCluster`** CR templates have a **`multiSiteHA`** section containing the placeholder **`$MULTI_SITE_HA`**, and it is this placeholder that must be replaced with the values for your deployment.

```
siteName: dallas
multiSiteHA:
  mode: active
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationdallas.cluster1.example.com
      secretName: dallas-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationraleigh.cluster2.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

```
siteName: raleigh
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationraleigh.cluster2.example.com
      secretName: raleigh-ptl-replication-worker-1
  replicationPeerFQDN:
ptlreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: ptl-replication-client
...
```

The configuration properties are described in the following table.

Table 1. The configuration properties of the multi-site HA section in the CR file

Configuration property	Description
`mode`	The state of the data center in the context of the two data center deployment. Valid values are: • `active` - indicates the primary data center • `passive` - indicates the warm-standby data center

`replicationEndpoint`
 	
`annotations:`
`cert-manager.io/issuer`
`hosts:`
`- name:`
 	
`secretName:`
	Contains details of the external ingress name for the subsystem in the current data center in the two data center deployment.
	The hosts `name` is a unique fully qualified hostname that the other data center uses to communicate with the current data center.

`replicationPeerFQDN`	The ingress hostname for the other data center in the two data center deployment. This information is required so that the two data centers can communicate with each other.
`tlsClient:` `secretName`	The TLS client secret for the subsystem.
`siteName`	A descriptive name for the Portal subsystem, and the Management subsystem, in the current data center, for example `dallas`. This name is used in the hostnames, and so can contain only `a-z` and `0-9` characters. Note that you can set a `siteName` in the `ManagementCluster` or `PortalCluster` CR only when the subsystems are first deployed, and you cannot change the name after deployment. If you don't set a `siteName` at first deployment, an automated `siteName` is created for you. For example, if you are converting an existing single Management cluster to a two data center Management cluster by adding the multi-site HA values, you will not be able to configure a `siteName` for the existing Management cluster.

To install a two data center disaster recovery deployment, you must set all of the placeholder properties in the CR file for both the Management and the Developer Portal subsystems as detailed in the relevant topics in the Installing the API Connect subsystems section, as well as the properties in the multi-site HA section that are detailed here. Some examples of complete CR files are shown in the Example section.

Procedure

- **Converting a single data center deployment to two data centers**
  When converting a single data center deployment into a two data center deployment, it is best practice to use the existing data center as the active one, and add a new warm-standby data center elsewhere. This practice ensures that the data is retained.
  Remember:
  - Both data centers must have the same `portal-admin` and `portal-www` endpoints.
  - You cannot configure a `siteName` for the existing Management or Portal cluster because the `siteName` property can be configured only at first deployment.

  The following example shows how to update the multi-site HA CR values for making the local data center called `dallas` (DC1) active, and for setting the new remote data center called `raleigh` (DC2) as warm-standby.

- Install cert-manager.
  Note: Run these steps on DC1 only if you don't already have cert-manager running.
  1. Obtain cert-manager.
     API Connect v10 uses cert-manager v1.16.3 of cert-manager, which is a native Kubernetes certificate management controller.

     You can obtain cert-manager v1.16.3 from the API Connect v10 distribution `helper_files.zip` archive, or from https://github.com/cert-manager/cert-manager/releases/tag/v1.16.3.

  2. Apply the CR:

     ```
     kubectl apply -f cert-manager-1.16.3.yaml
     ```

     Do not specify a custom namespace.

     See https://docs.cert-manager.io/en/release-0.10/getting-started/install/kubernetes.html.

  3. Wait for `cert-manager` pods to enter `Running 1/1` status before proceeding. To check the status:

     ```
     kubectl get po -n cert-manager
     ```

     There are 3 `cert-manager` pods in total.
- Use the following steps to allow `ingress-ca` secrets to be the same on both data centers.
  1. On DC1 apply the file `ingress-issuer-v1-dc1.yaml`:

     ```
     kubectl -n <namespace> apply -f ingress-issuer-v1-dc1.yaml
     ```

  2. Validate that the command succeeded:

```
kubectl get certificates -n <namespace>
```

3. Export `ingress-ca` secret as a yaml from DC1:

   ```
   kubectl -n <namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
   ```

4. Edit the `ingress-ca.yaml` file to remove all labels, annotations, `creationTimestamp`, `resourceVersion`, `uid`, and `selfLink`.
5. Copy the `ingress-ca.yaml` from DC1 to DC2 and apply that file on DC2:

   ```
   kubectl -n <namespace> apply -f ingress-ca.yaml
   ```

6. On DC2 apply the file `ingress-issuer-v1-dc2.yaml`:

   ```
   kubectl -n <namespace> apply -f ingress-issuer-v1-dc2.yaml
   ```

7. Use the following commands to test that they are the same, on DC1 run:

   ```
   kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
   /tmp/ingress.pem.dc1
   ```

8. On DC2 run:

   ```
   kubectl -n <namespace> get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
   /tmp/ingress.pem.dc2
   ```

9. To see the differences run:

   ```
   diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
   ```

   The files should be the same.
10. To ensure that the certificates are working correctly and that they are using the `ingress-ca` secret. First, get the `portal-admin-client crt` file:

    ```
    kubectl -n <namespace> get secrets portal-admin-client -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
    /tmp/admin-client.crt
    ```

11. Test that it is working by using OpenSSL:

    ```
    openssl verify -verbose -CAfile /tmp/ingress.pem.dc1 /tmp/admin-client.crt
    ```

    If it is working, you should see:

    ```
    /tmp/admin-client.crt: OK
    ```

- **Installing to an active data center**
  The following example shows how to set the multi-site HA CR values for deploying to an active data center (DC). In this instance, we are deploying to a local data center called `dallas` (DC1) that has a remote data center called `raleigh` (DC2).

  1. Set Dallas to be active for the API Manager service on DC1.
     As the API Manager service already exists, you cannot set the `siteName` property. Add the multi-site HA section properties to the existing `ManagementCluster` CR file for DC1. For example:

     ```
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: mgrreplicationdallas.cluster1.example.com
           secretName: dc1-mgmt-replication
       replicationPeerFQDN: mgrreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: dc1-mgmt-replication-client
     ```

  2. Set Dallas to be active for the Developer Portal service on DC1.
     As the Developer Portal service already exists, you cannot set the `siteName` property. Add the multi-site HA section properties to the existing `PortalCluster` CR file for DC1. For example:

     ```
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: ingress-issuer
         hosts:
         - name: ptlreplicationdallas.cluster1.example.com
           secretName: dallas-ptl-replication-worker-1
       replicationPeerFQDN: ptlreplicationraleigh.cluster2.example.com
       tlsClient:
         secretName: ptl-replication-client
     ```

  3. Create a secret called `ptl-encryption-key` on the active and warm-standby data centers.
     You must create a secret on the active and warm-standby sites that use the same random string, run the following command:

     ```
     kubectl create secret generic ptl-encryption-key --from-literal=encryption_secret=<RANDOM STRING> -n <namespace>
     ```

     The string can consist of uppercase letters, lowercase letters, and numbers, and must be at least 64 characters and no more than 100 characters.

  4. When the secrets are created on both DC1 and DC2, update the Portal CR on DC1 and DC2 to include in the `spec` object:

     ```
     encryptionSecret:
       secretName: ptl-encryption-key
     ```

     Warning: Ensure that you add the secret to the `spec` object and not to the `multiSiteHA` object.
  5. Apply the CR files to the subsystems in DC1.

For example, to apply the `ManagementCluster` CR file to the DC1 cluster, run the following command:

```
kubectl apply -f management_cr.yaml -n <namespace>
```

Where `<namespace>` is the target installation namespace in the Kubernetes cluster for DC1. Repeat this process to apply the updated `PortalCluster` CR file to DC1.
You can verify that the updated CR files have been applied by running the following command:

```
kubectl get ManagementCluster -n <namespace>
```

You can verify that the installation process is running with the following command:

```
kubectl get ManagementCluster -n <namespace>
```

Note: Until the warm-standby is installed and running, the `haStatus` reports `PeerNotReachable`.
Change `ManagementCluster` to `PortalCluster` to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

6. Set your dynamic router to direct all traffic to DC1.
   This includes setting the four endpoints for the API Manager cluster, and the two endpoints for the Developer Portal cluster.

- **Installing to a warm-standby data center**
  The following example shows how to set the multi-site HA CR values for the remote data center called `raleigh` (DC2), which is being installed as the warm-standby, standby location. You must use the same encryption key on both sites.

1. Get the encryption key from Dallas the `active` (DC1) site:
   a. Run the command `kubectl get mgmt -o yaml|grep enc` to get the db encryption key on the `active` site, for example:

      ```
      $ kubectl -n <namespace> get mgmt -o yaml|grep enc
      ```

      An example of possible output:

      ```
      encryptionSecret: dallas-enc-key
      ```

      Make a note of the secret name. In this case, it's `dallas-enc-key`.
   b. Run `kubectl get secret dallas-enc-key -o yaml`, an example of possible output:

      ```
      apiVersion: v1
      data:
        encryption_secret.bin:
      VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
      pyLiY5g*******************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
      kind: Secret
      metadata:
        creationTimestamp: "2020-08-28T12:53:41Z"
        labels:
          app.kubernetes.io/instance: m1
          app.kubernetes.io/managed-by: ibm-apiconnect
          app.kubernetes.io/name: dallas-enc-key
        name: dallas-enc-key
        namespace: default
        resourceVersion: "43039"
        selfLink: /api/v1/namespaces/default/secrets/m1-enc-key
        uid: 46c92395-9cc2-4421-b2c4-48e472c0cbb1
      type: Opaque
      ```

   c. Copy the output that you got and put it into a new file. Delete the contents of `metadata:` and add back in a `name:` attribute, in this case `dc1-enc-key`. An example of the format is here:

      ```
      apiVersion: v1
      data:
        encryption_secret.bin:
      VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
      pyLiY5g*******************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
      kind: Secret
      metadata:
        name: dc1-enc-key
      type: Opaque
      ```

   d. Save the file. In this example, it's called `dc1-enc-key.yaml`.
2. On Raleigh the (DC2) site:
   a. Copy the yaml file that you just saved that contains the `encryption_secret.bin` from Dallas the `active` (DC1) site.
   b. Run `kubectl create -f dc1-enc-key.yaml` to create the same secret with the same key on the Raleigh (DC2) site. For example:

      ```
      $ kubectl  -n <namespace> create -f /tmp/dc1-enc-key.yaml
      ```

      An example of possible output:

      ```
      secret/dc1-enc-key created
      ```

   c. In the management CR for Raleigh the (DC2) site, add the following entry to the `spec`.

      ```
      encryptionSecret:
          secretName: dc1-enc-key
      ```

3. Set Raleigh to be warm-standby for the API Manager service on DC2.
   Edit the `ManagementCluster` CR file management_cr for DC2, and set the multi-site HA section properties, for example:

```
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manage.io/issuer: ingress-issuer
```

```
    hosts:
    - name: mgrreplicationraleigh.cluster2.example.com
      secretName: raleigh-mgr-replication-worker-1
  replicationPeerFQDN: mgrreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: mgr-replication-client
...
siteName: raleigh
```

4. Set Raleigh to be warm-standby for the Developer Portal service on DC2.
   Edit the `PortalCluster` CR file portal_cr for DC2, and set the multi-site HA section properties, for example:

```
multiSiteHA:
  mode: passive
  replicationEndpoint:
    annotations:
      cert-manage.io/issuer: ingress-issuer
    hosts:
    - name: ptlreplicationraleigh.cluster2.example.com
      secretName: raleigh-ptl-replication-worker-1
  replicationPeerFQDN: ptlreplicationdallas.cluster1.example.com
  tlsClient:
    secretName: ptl-replication-client
...
siteName: raleigh
```

5. Ensure that you completed the steps that are in the **Installing to an active data center** section to create a secret called `ptl-encryption-key` on DC1 and DC2, and to update the Portal CR on DC1 and DC2 to include the `ptl-encryption-key` in the `spec` object.
6. Apply the CR files to the subsystems in DC2.
   For example, to apply the `ManagementCluster` CR file to the DC2 cluster, run the following command:

   ```
   kubectl apply -f management_cr.yaml -n <namespace>
   ```

   Where `<namespace>` is the target installation namespace in the Kubernetes cluster for DC2. Repeat this process to apply the updated `PortalCluster` CR file to DC2.
   You can verify that the updated CR files are applied by running the following command:

   ```
   kubectl get ManagementCluster -n <namespace>
   ```

   You can verify that the installation process is running with the following command:

   ```
   kubectl get ManagementCluster -n <namespace>
   ```

   When installation is complete, `haStatus` reports `Ready`.
   Change `ManagementCluster` to `PortalCluster` to verify the Developer Portal installation. For more information, see Installing the API Connect subsystems.

Related concepts

- Maintaining a two data center deployment

Troubleshooting installation on Kubernetes

Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on Kubernetes

- DataPower operator fails to start

DataPower operator fails to start

There is a known issue on Kubernetes that can cause the DataPower operator to fail to start. In this case, the DataPower operator pods can fail to schedule, and display the status message: `no nodes match pod topology spread constraints (missing required label)`. For example:

```
0/15 nodes are available: 12 node(s) didn't match pod topology spread constraints (missing required label),
3 node(s) had taint {node-role.kubernetes.io/master: }, that the pod didn't tolerate.
```

You can workaround the issue by editing the DataPower operator deployment and reapplying it, as follows:

1. Delete the DataPower operator deployment, if deployed already:

   ```
   kubectl delete -f ibm-datapower.yaml -n <namespace>
   ```

2. Open `ibm-datapower.yaml`, and locate the `topologySpreadConstraints:` section. For example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: zone
     whenUnsatisfiable: DoNotSchedule
   ```

3. Replace the values for `topologyKey:` and `whenUnsatisfiable:` with the corrected values that are shown in the following example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: topology.kubernetes.io/zone
     whenUnsatisfiable: ScheduleAnyway
   ```

4. Save `ibm-datapower.yaml` and deploy the file to the cluster:

```
kubectl apply -f ibm-datapower.yaml -n <namespace>
```

Deploying on OpenShift and Cloud Pak for Integration

You can install API Connect in an OpenShift environment or as the API Management capability in IBM Cloud Pak for Integration.

The recommended configuration is to have a single operator in the global namespace, managing multiple API Connect instances in separate namespaces.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

- **Configuring FIPS support on OpenShift**

Configuring FIPS support on OpenShift

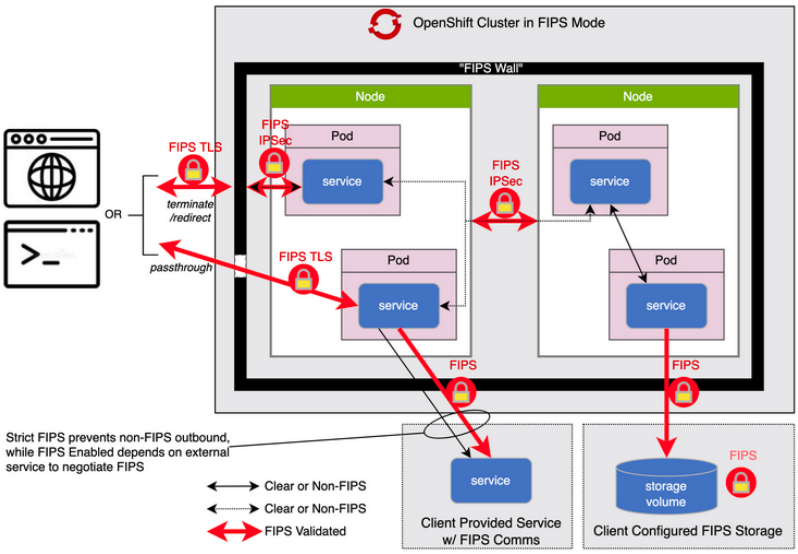
Configure support for FIPS (Federal Information Processing Standards) on the cluster where you will install IBM API Connect.

Before you begin

API Connect supports FIPS with the following limitations:

- Only FIPS version 140-2 is supported
- FIPS must be configured on the cluster before you install API Connect
- You must deploy API Connect 10.0.8.2-ifix1 or later.
- The version of DataPower Gateway that is compatible with v10.0.8.x does not support FIPS:
  - Known limitations and restrictions
  - Cloud Pak for Integration - Gateway instance additionally notes the FIPS and FIPS-Wall status

About this task



To be FIPS compliant, an organization must adhere to the various data security and computer system standards outlined in the FIPS requirements. FIPS compliance for API Connect is supported by implementing a "FIPS wall".

What is FIPS?

Federal Information Processing Standards (FIPS) are standards and guidelines issued by the National Institute of Standards and Technology (NIST) for federal government computer systems. The standards are developed when there are compelling federal government requirements for standards, such as for security and interoperability, but acceptable industry standards or solutions do not exist. Government agencies and financial institutions use these standards to ensure that products conform to specified security requirements.
API Connect supports version 140-2 of the FIPS requirements, implemented using the "FIPS wall" approach.

What is a FIPS wall?

The "FIPS wall" is a boundary approach to FIPS compliance that is used by IBM products. All pods in the cluster are FIPS-tolerant (the pods can run without issues on a FIPS-enabled OpenShift cluster), while creating a compliant "boundary" that is secured at external points of contact (known as "touch points").
Traffic inside the boundary is secure because the communication between nodes is automatically encrypted at the OpenShift Container Platform level using the IPSec protocol. Traffic within any node happens in-memory, so it never leaves the node. The following diagram illustrates a typical OpenShift cluster that is configured to support the FIPS wall. In the diagram, the "wall" is represented with a heavy black border. Communications between pods within the border are secured with IPSec encryption, and communications that cross the border to external devices are secured using other means for example, TLS encryption).

What are the cluster requirements to support a FIPS wall?

- FIPS is enabled on the cluster during installation (by setting `fips: true` in the install-config.yaml file)
- FIPS is enabled for node-to-node communication (using the OVN-Kubernetes Container Network Interface cluster network provider, and with IPSec enabled)
- The etcd key-value store is encrypted with `aescbc`
- Storage is encrypted with FIPS ciphers
- Runtimes are managed using Kubernetes CRI-O (all OCP deployments use CRI-O by default)

What are the Red Hat OpenShift Container Platform dependencies?

API Connect 10.0.8.2-ifix1 can be deployed with the following version of OpenShift Container Platform (OCP):

- Versions 4.12 to 4.18
- FIPS compliance
  - Different OCP versions have varying levels of FIPS 140-2 and FIPS 140-3 certifications. For detailed information on FIPS compliance for specific OCP versions, refer to the Compliance Activities and Government Standards section in the Red Hat Customer Portal.

Install and configure OpenShift Container Platform

Configure settings for FIPS and IPSec, install the OpenShift cluster, and then configure the cluster to enable encryption and provide storage.

Procedure

1. Configure settings in the install-config.yaml file.
   Edit the install-config.yaml and make the following changes:

   - Set `fips: true`
   - Set the `networkType` to `OVNKubernetes`

   For example:

```
networking:
  clusterNetwork:
  - cidr: 10.128.0.0/14
    hostPrefix: 23
  networkType: OVNKubernetes
  serviceNetwork:
  - 172.30.0.0/16
fips: true
```

   For an example of the install-config.yaml file, see Sample install-config.yaml file for bare metal in the Red Hat OpenShift documentation.

2. Create the IPSec installation manifests to allow IPSec tunneling for node-to-node communication in the OpenShift cluster.
   a. Generate the manifests from `install-config.yaml` by running the following command:

```
openshift-install create manifests
```

   b. Create a cluster-network-03-config.yaml file with the following content, and save it in the `manifests` directory:

```
apiVersion: operator.openshift.io/v1
kind: Network
metadata:
  name: cluster
spec:
  defaultNetwork:
    type: OVNKubernetes
    ovnKubernetesConfig:
      ipsecConfig: {}
      mtu: 1400
```

3. Deploy the OpenShift cluster.
   Install the OpenShift cluster, and then install the OpenShift CLI.

a. Install the OpenShift cluster as explained in Chapter 2. Installing the system in FIPS mode in the Red Hat OpenShift "FIPS support" documentation.
b. Install the OpenShift CLI (oc) as explained in Installing the OpenShift CLI in the Red Hat OpenShift documentation.

4. Log in to the cluster as a user with `cluster-admin` privileges.

5. Validate the OpenShift cluster.
   a. Verify that FIPS is enabled on the OpenShift cluster.
      i. Run the following command to verify the `fips` setting:

```
oc get cm cluster-config-v1 -n kube-system -o json | jq -r '.data."install-config"' | grep -i "fips"
```

Review the results and verify that the `fips` setting is set to `true`:

```
fips: true
  name: fips-apic
  root@fips-apic
```

      ii. Run the following command to get the names of the machine configurations:

```
oc get mcp
```

In the result, the configuration name appears in the `CONFIG` column; for example:

```
NAME     CONFIG                                             UPDATED   UPDATING   DEGRADED   MACHINECOUNT
READYMACHINECOUNT   UPDATEDMACHINECOUNT   DEGRADEDMACHINECOUNT   AGE
master   rendered-master-41831cf684b6e570518728abd24b9006   True      False      False      3              3
3                   0                     15h
worker   rendered-worker-2a4937983238e94a74307abc3eed2080   True      False      False      7              7
7                   0                     15h
```

For each configuration listed in the result, run the following command to verify that `Fips` is set to `true`:

```
oc describe mc <CONFIG> | grep Fips
```

The previous example returned two configurations, so run the command on each configuration:

- `oc describe mc rendered-master-41831cf684b6e570518728abd24b9006 | grep Fips`
  `Fips:  true`
- `oc describe mc rendered-worker-2a4937983238e94a74307abc3eed2080 | grep Fips`
  `Fips:  true`

   b. Verify that IPSec is enabled on the OpenShift cluster.
      i. Check the `ovn-ipsec` daemonset that manages the daemons responsible for configuring IPSec:

```
oc get ds -n openshift-ovn-kubernetes ovn-ipsec
```

A successful result looks like the following example:

```
NAME        DESIRED   CURRENT   READY   UP-TO-DATE   AVAILABLE   NODE SELECTOR                 AGE
ovn-ipsec   66666           beta.kubernetes.io/os=linux   3d3h
```

      ii. Verify that IPSec pods are running in all of the nodes in your OpenShift cluster:

```
oc get pod -n openshift-ovn-kubernetes -o wide | grep ipsec
```

A successful result looks like the following example:

```
 ovn-ipsec-4qp86        1/1     Running   0          38m   192.168.7.23   master2.ocp4.rober.lab   <none>
<none>
 ovn-ipsec-pk7vh        1/1     Running   0          38m   192.168.7.21   master0.ocp4.rober.lab   <none>
<none>
 ovn-ipsec-q4mwj        1/1     Running   0          22m   192.168.7.11   worker0.ocp4.rober.lab   <none>
<none>
 ovn-ipsec-trz5m        1/1     Running   0          22m   192.168.7.12   worker1.ocp4.rober.lab   <none>
<none>
 ovn-ipsec-vjmw8        1/1     Running   0          38m   192.168.7.22   master1.ocp4.rober.lab   <none>
<none>
```

6. Enable `etcd` encryption Encrypting etcd datawith `aescbc` as explained in in the Red Hat OpenShift documentation.

7. For local storage, choose either RHEL-provided disk encryption or Container Native Storage that uses RHEL-provided disk encryption.
   By storing all data in volumes that use RHEL-provided disk encryption and enabling FIPS mode for your cluster, both data at rest and data in motion (network data) are protected by FIPS-validated or Modules In Process encryption. You can configure your cluster to encrypt the root filesystem of each node, as described in Customizing nodes in the Red Hat OpenShift documentation.

Install API Connect

Install API Connect on the OpenShift cluster, and ensure that server connections support FIPS.

Procedure

1. Install API Connect.
   For instructions on installing API Connect with subsystem CRs, see Installing API Connect in a single namespace on OpenShift or Installing API Connect subsystems in different namespaces or environments on OpenShift in this documentation.

2. Ensure that all server connections support FIPS.

   Inbound connections support FIPS by default
   All inbound connections support FIPS by default, except for the Gateway which does not support FIPS and should not be used in a FIPS-Wall environment.

   Outbound connections: Ensure that all of the outbound connections support FIPS

For outbound connections, it is your responsibility to ensure that the external servers configured with API Connect accept only FIPS connections. The following list shows the typical outbound connections for an API Connect deployment

- OIDC providers (Google, Facebook, Keycloak etc.)
- LDAP providers
- Authentication URLs
- External user registry
- Target URLs used in APIs
- Remote backups
- Auditing endpoints
- SMTP endpoints
- Analytics offloading
- Analytics backup to S3 storage
- Automated API behavior testing tool (ATM) - calls out to the APIs being tested
- Portal - Potential drupal extensions installed by customer
- Portal - SFTP and S3 backups
- 2-data-center deployments - Calls to other clusters

Preparing for installation

Set up your OpenShift environment in preparation for deploying API Connect.

About this task

Ensure that your environment meets all prerequisites, plan your deployment, and download files for installation.

Procedure

1. Ensure that your environment meets the following prerequisites:
   - IBM API Connect Version 10 software product compatibility requirements
   - Deployment requirements
   - If you want to use the OpenShift web console, Cluster admin access is required.
   - API Connect requires **`block storage`** as the storage class for all subsystems.
   - Set the default SCC (security context constraint) to **`restricted`**.
     API Connect supports only the **`restricted`** SCC on OpenShift.
   - If your OpenShift deployment uses a LimitRange and a CPU **`maxLimitRequestRatio`** is set, then its value must be at least 25; otherwise some API Connect pods might fail to start.
   - S3 object-store available for storing API Connect subsystem database backups.
2. Plan your deployment as explained in Planning your deployment.
3. Review Operator, CASE, and platform requirements to determine the operator, operand, and CASE versions that you need for your deployment.
4. Obtain the API Connect files..
   From the IBM Fix Central site, download the following files:

   IBM® API Connect *<version>* for Containers
   : Docker images for all API Connect subsystems. Filename is apiconnect-image-tool_*<version>*.

   IBM® API Connect *<version>* Operator Release Files for Containers
   : Kubernetes operators and API Connect Custom Resource (CR) templates. Filename is apiconnect-operator-release-files_*<version>*.

   IBM API Connect *<version>* Security Signature Bundle File
   : Signature files for verifying the integrity of your downloads.
   Filename is signatures_*<version>*.

   IBM API Connect *<version>* Toolkit for *<operating_system>*
   : Toolkit command-line utility. Packaged as a stand-alone file, or with API Designer:
     - IBM API Connect *<version>* Toolkit for *<operating_system>*
     - IBM API Connect *<version>* Toolkit Designer for *<operating_system>*

   Filename is toolkit-...*<operating system>*_*<version>*.
   Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI as explained in Installing the toolkit.

   IBM API Connect *<version>* Local Test Environment
   : Optional test environment for testing locally as explained in Testing an API with the Local Test Environment.
   Filename is apic-lte-*<operating system>*_*<version>*.

5. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
6. Decide whether to install API Connect with a top-level CR, or with individual subsystem CRs, or using Cloud Pak for Integration.
   Installing with a top-level CR means you have a single **`APIConnectCluster`** CR which includes sections for all subsystem CRs: Management, Gateway, Analytics, and Portal. Installing with individual subsystem CRs means no **`APIConnectCluster`** CR, only subsystem CRs, for example **`ManagementCluster`**, **`PortalCluster`**.
7. Optional: Specify additional settings in each subsystem CR to define the deployment's configuration before beginning the installation.
   In particular, consider increasing the timeout value for Management endpoints as explained in Configuring timeouts for management endpoints.

   For information on other configuration settings, see API Connect configuration settings.

   Tip: If you choose not to specify configuration settings now, you can modify the installation CRs later and then re-apply them to update the deployment.

- **Operator, CASE, and platform requirements**
  Before you install API Connect on Red hat OpenShift Container Platform, verify that you are using the correct operator, CASE file (for air-gapped installations), and OpenShift version.
- **API Connect configuration settings**
  Specify configuration settings for API Connect in the CR, or the Platform UI in Cloud Pak for Integration.
- **Configuring timeouts for management endpoints**
  Adjust the timeout settings for management endpoints by updating the CR.

Operator, CASE, and platform requirements

Before you install API Connect on Red hat OpenShift Container Platform, verify that you are using the correct operator, CASE file (for air-gapped installations), and OpenShift version.

Remember: If installing the APIC 10.0.8.x with CP4I, then you must use the SC2 version of CP4I, specifically the version 16.1.0. Remember that the installation of APIC 10.0.8.x with the CD versions of CP4I such as 16.1.1 is not supported.
Table 1 lists the operator, operand, and CASE information that applies to API Connect.

Supported versions of operators for API Connect

Table 1 lists the operators that are used for the newest version of API Connect

Table 1. Operators for installing and upgrading API Connect

API Connect version	API Connect Operator channel	API Connect Operator version	Data Power version	DataPower Operator version	Foundational services CASE version
10.0.8.2-ifix1	v5.4-sc2	5.4.1	10.6.0.4	1.11.5	4.6.x

You can run the API Connect operator and subsystems at different versions. The following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
5.4.1	• 10.0.8.2-ifix1 • 10.0.8.1 • 10.0.8.0
5.3.0	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

CASE versions required for air-gapped installation and upgrade

Table 2 lists the required CASE file for each API Connect release:

Table 3. CASE versions for air-gapped deployments

API Connect version	API Connect CASE version	Foundational services CASE version	EDB CASE version
10.0.8.2-ifix1	5.4.1	`4.6.x`	5.12.0+20250113.184627.2261

Supported versions of Red Hat OpenShift Container Platform

Table 3 provides a quick reference of the supported OpenShift versions for each API Connect release:

Table 4. API Connect and OpenShift Container Platform (OCP) compatibility

API Connect version	OCP 4.10	OCP 4.12	OCP 4.14	OCP 4.16	OCP 4.17	OCP4.18
10.0.8.2-ifix1		✓	✓	✓	✓	✓

API Connect configuration settings

Specify configuration settings for API Connect in the CR, or the Platform UI in Cloud Pak for Integration.

You can use the Platform UI on Cloud Pak for Integration, the OpenShift web console, or direct editing of the top-level or subsystem CR YAML files to specify advanced configuration options for API Connect. The following topics describe the available configuration options.

Attention: A mistake in a configuration update can result in an admission webhook error when `APIConnectCluster` is updated, or the `APIConnectCluster` can get stuck in a pending state with a webhook error message.

- Example of an admission webhook error when the `APIConnectCluster` update is rejected:
  In this example, the user attempted to change the deployment profile to `n12xc4.m12-incorrect` and the result looked like the following example:

```
oc edit apiconnectcluster
```

```
error: apiconnectclusters.apiconnect.ibm.com "production" could not be patched: admission webhook
"vapiconnectcluster.kb.io" denied the request: APIConnectCluster.apiconnect.ibm.com "production" is invalid: spec.Profile:
Invalid value: "n12xc4.m12-incorrect": invalid profile. Options are: [n3xc4.m16 n12xc4.m12]
```

- Example of when the `APIConnectCluster` update is allowed, but is the state changes pending due to an underlying webhook error:

```
oc get apiconnectcluster -n apic

NAME    READY   STATUS    VERSION             RECONCILED VERSION   AGE
m1      admission webhook "vmanagementcluster.kb.io" denied the request: ManagementCluster.management.apiconnect.ibm.com
"m1-mgmt" is invalid: [spec.databaseBackup.restartDB.accept: Invalid value: false: databaseBackup protocol has changed
(from '' to 'objstore') and requires database restart. accept restartDB to restart database,
spec.databaseBackup.restartDB.accept: Invalid value: false: databaseBackup configuration has changed and requires database
restart. accept restartDB to restart database]   Pending   10.0.1.5-3388-eus   10.0.1.5-3388-eus    2d6h
```

Basic configuration

- Basic configuration settings

Advanced configuration

To enable access to the advanced configuration settings with Platform UI, toggle the Advanced Options slider.

- Analytics subsystem settings
- Gateway subsystem settings
- Management subsystem settings
- Developer Portal subsystem settings
- Additional Kubernetes settings

Additional configuration

You must edit the yaml file to set additional properties.

- **Basic configuration settings**
  You can specify the API Connect basic configuration settings directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Management subsystem settings**
  You can specify advanced configuration settings for the Management subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Gateway subsystem settings**
  You can specify advanced configuration settings for the Gateway subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Developer Portal subsystem settings**
  You can specify advanced configuration options for the Developer Portal subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.
- **Analytics subsystem settings**
  Specify advanced configuration settings for the analytics subsystem directly in the analytics CR. If you are using Cloud Pak for Integration, you can configure many of the analytics settings in Platform UI.
- **Additional Kubernetes settings**
  For each API Connect subsystem, you can specify additional settings for annotations and pod management.

Basic configuration settings

You can specify the API Connect basic configuration settings directly in the CR or with the Platform UI in Cloud Pak for Integration.

Review the tables for information on configuration settings for the following areas:

- Details
- License
- Deployment profiles for installing with a single, top-level CR
- Product version
- Storage class

Details

Table 1. Details

Field	Type	Required	Description
Name	String	Yes	Name this instance using only lowercase alphanumeric characters plus the underscore "-". Maximum of 54 characters. Default: none

License

Table 2. License

Field	Type	Required	Description
License acceptance	Boolean	Yes	The license agreement https://ibm.biz/apictoolkitlic must be accepted before you can install the API Connect capability. Default value: `false` (off). In the UI, click the License acceptance toggle to enable it. In the CR, set the `accept:` field to `true` to accept the license.
License use	String	Yes	Select `production` or `nonproduction`, to match the license you purchased. Default: `nonproduction`

Field	Type	Required	Description
License metric	Enumerated	No	Enter the unit of measure that is used for your program license: OpenShift • PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used. • MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program. Cloud Pak for Integration • VIRTUAL_PROCESSOR_CORE - Default value. If you leave the field blank, this value is used. • MONTHLY_API_CALL - Applies only to the IBM Cloud Pak for Integration - API Calls add-on program. For information on tracking monthly call volume, see Tracking API volume for auditing and compliance.
License ID	String	Yes	Select the license that you purchased for this instance of API Connect. Valid licenses are based on the selected value in the Product version field (see Table 4). When deploying the standalone IBM API Connect product, you must select the License ID for the API Connect program that you purchased. To view all License IDs, see API Connect licenses.

Deployment profiles for installing with a single, top-level CR

Select a deployment profile for the new installation. See API Connect deployment profiles for OpenShift and Cloud Pak for Integration for more information on the available profiles.

For information on switching to a different deployment profile after installation, see the following topics:

- Changing the deployment profile on Cloud Pak for Integration
- Changing deployment profiles on OpenShift top-level CR

Product version

Table 3. Product version

Field	Type	Required	Description
Product version	Enumerated	No	Select the product version to be installed in the system. Warning: Do not select a channel here instead of the API Connect version. Selecting a channel will result in any API Connect interim fix updates being applied automatically and without warning.

Storage class

Table 4. Storage class

Field	Type	Required	Description
Default Storage Class	Enumerated	No	Specify the RWO block storage class to use for persistence storage. This will be used when creating a PVC. Specification of the storage class is optional, but is highly recommended. If not specified the default cluster storage class is used. See the IBM Cloud Pak documentation for guidance for Storage class selection. Go to the following page and select your Cloud Pack release level: https://www.ibm.com/support/knowledgecenter/SSGT7J. In the navigation panel, select System Requirements > Storage. To review API Connect storage support, see Storage classes.

Management subsystem settings

You can specify advanced configuration settings for the Management subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.

The IBM Cloud Pak Platform UI enables you to specify settings for the following areas:

For annotations, labels, node selectors, and tolerations, see Additional Kubernetes settings

Note: Optionally, you might want to increase the timeout settings for management endpoints, particularly for large deployments. See Configuring timeouts for management endpoints.

Database backups settings

Table 1. Database backup

Field	Type	Required	Description
Credentials	Drop down menu	Yes	The name of the Kubernetes secret containing your S3 access key and secret or your or SFTP username and password or SSH key. Default: (Generated Value) See Configuring management database backups.

Field	Type	Required	Description
Server hostname	String	Yes	Hostname of your remote SFTP backup server or object-store endpoint. If specifying an S3 object-store, use the format **<S3endpoint>/<S3region>**. For example: **s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard** Default: none See Configuring management database backups.
Path	String	Yes	The path to the location of for your backups on your remote server. If you are using a remote SFTP server, then this is a directory path. If you are using an object-store, then this is the name of your S3 bucket. For example, **bucket-name/folder**. The use of subdirectories in the bucket name is not supported. Ensure that **bucket-name/folder** is empty. Default: none See Configuring management database backups.
Port	Integer	No	If you are using a remote SFTP server, set this to the port the SFTP server listens on. Default is 22.
Protocol	String	Yes	Set according to your remote backup site as follows: • SFTP: Set **protocol=sftp**. • Object-store: Set **protocol=objstore**. • None: Set **local**. Backups are kept on local persistent storage.
Schedule	String	Yes	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * * • - - - - - - • | | | | | | • | | | | | +----- day of week (0 - 6) (Sunday=0) • | | | | +------- month (1 - 12) • | | | +--------- day of month (1 - 31) • | | +----------- hour (0 - 23) • | +------------- min (0 - 59) • +--------------- sec (0 - 59) The backup schedule defaults to **0 0 * * * ***. This means a backup is run every day at midnight and minute zero UTC. When you configure a host, if you do not specify a value for **schedule**, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed. See Configuring management database backups.
Backup certs	Drop down menu	Optional, if S3 object-store requires them.	Secret containing the CA certificate for your S3 object-store. Required for API Connect to trust the S3 object-store.
RepoRetentionFull	Integer	Yes	The number of days to retain backups for. For example, if **RepoRetentionFull** is set to 30, then any backups older than 30 days are deleted.
Backup S3 URI Style	Drop down menu	**host**	Indicates whether URIs to your S3 backup specify a host or a path value. Set to either **host** or **path**.

Database persistence

Table 2. Database persistence

Field	Type	Required	Description
Storage Class	Drop down menu	No. Optional	Specify the RWO block storage class to use for persistence storage. This will be used when creating a PVC. Specification of the storage class is highly recommended. If not specified the default cluster storage class is used. See the IBM Cloud Pak documentation for guidance for Storage class selection. Go to the following page and select your Cloud Pack release level: https://www.ibm.com/support/knowledgecenter/SSGT7J. In the navigation panel of the KC, select System Requirements > Storage. To review API Connect storage support, see Storage classes.
Volume size	Integer	No. Optional	Represents the size of the Database volume. Defaults to 120G for **n1xc4.m16** installation profile, 180G for **n3xc4.m16** installation profile.

Site name

Table 3. Site Name

Field	Type	Required	Description

Field	Type	Required	Description
Site name	string	No. Optional	Site name is the logical name of this failure domain. Typically site name is the name of your data center, such as Amazon AZ. Default: randomly generated name. This will be the site name of the management deployment. For example, given the site name of **`test`** your management deployment will look like **`management-test-postgres`**.

Test and Monitor

Table 4. Test and Monitor

Field	Type	Required	Description
Enable Test and Monitor	Boolean. Toggle off/on	No. Optional	Test and Monitor automatically generates API test assertions. It contains dashboards for monitoring API test assertions and getting alerts on the health of your APIs. Default: off See Installing the Automated API behavior testing application.

Billing

Table 5. Billing

Field	Type	Required	Description
Enable Billing	Boolean. Toggle off/on	No. Optional	To enable the monetization of your Product Plans, you must add a billing integration resource in your API Connect provider organization that defines the configuration data needed to synchronize with an external subscription billing system. Default: off See Adding a billing integration resource.

Gateway subsystem settings

You can specify advanced configuration settings for the Gateway subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.

The IBM Cloud Pak Platform UI enables you to specify settings for the following areas:

- v5 compatibility mode
- Operations Dashboard
- Token management service
- Autoscaling gateway pods

For annotations, labels, node selectors, and tolerances, see Additional Kubernetes settings

v5 compatibility mode

Table 1. v5 compatibility mode

Field	Type	Required	Description
V5 comparability mode	Toggle Switch off/on	No. Optional	Enabling this provides v5 compatibility (trading off some performance) with the IBM DataPower Gateway that was provided with IBM API Connect Version 5 and earlier releases. Consider using this DataPower Gateway (v5 compatible) if you are an existing DataPower user and want to utilize your DataPower resources and knowledge. Default: off To review v5 compatibility, see API Connect gateway types.

Operations Dashboard

Table 2. Operations Dashboard

Field	Type	Required	Description
Enable Operations Dashboard tracing	Toggle Switch off/on	No. Optional	Enable or disable cross-component transaction tracing to allow troubleshooting and investigating errors and latency issues. Default: disabled (off) To review the Operations Dashboard, see https://www.ibm.com/support/knowledgecenter/SSGT7J_20.3/tracing/operations_dashboard.html For information on configuring the Operations Dashboard, see https://ibm.github.io/datapower-operator-doc/apis/datapowerservice/v1beta2/#odtracing.
Operations Dashboard namespace	string	No. Optional	Namespace where the IBM Cloud Pak for Integration Operations Dashboard has been deployed. Default: none
Replica count	string	No. Optional	Specify the number of instances of the Gateway that should be deployed. For high-availability, a minimum of 3 replicas (one per node) is recommended. Default: none

Token management service

Table 3. Token management service

Field	Type	Required	Description
Advanced: Enable TMS	Toggle Switch	No. Optional	Enable or disable token management service (TMS) to use the DataPower to manage the token lifecycle.. Default: disabled (off) The Token Management Service uses the DataPower distributed cache to manage the token lifecycle which includes when to revoke access rights. For more information, see Token management with DataPower API Gateway.
Advanced: Storage Class	string	No. Optional	Specify the RWO block storage class to use for persistence storage. This will be used when creating a PVC. Specification of the storage class is highly recommended. If not specified the default cluster storage class is used. See the IBM Cloud Pak documentation for guidance for Storage class selection. Go to the following page and select your Cloud Pack release level: https://www.ibm.com/support/knowledgecenter/SSGT7J. In the navigation panel of the KC, select System Requirements > Storage. To review DataPower storage configuration, see https://ibm.github.io/datapower-operator-doc/apis/datapowerservice/v1beta2/#storage.
Advanced: Volume size	string	No. Optional	Resources represents the minimum resources the volume should have. For example, 10Gi.Default: none To review DataPower storage configuration, see `storage` API. in the DataPower documentation.

Autoscaling gateway pods

Autoscaling enables the gateway deployment to scale dynamically, either vertically or horizontally. It is not possible to use both horizontal and vertical pod scaling simultaneously. You must configure either **`HPA`** (for horizontal scaling) or **`VPA`** (for vertical scaling) as the scaling method.

Note: DataPower Gateway supports long-lived connections such as such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when pods are scaled down based on defined CPU or memory thresholds. Workloads with long-lived connections are more vulnerable to failed API transactions when auto-scaling is occurring.
To learn more about HPA and VPA autoscaling, see the following topics in the DataPower documentation:

- Autoscaling DataPower Pods
- **`podAutoScaling`** API

You can configure autoscaling for Gateway pods by inserting a new subsection in the **`spec`**
`gateway` section of the top-level CR, or by filling in the corresponding fields in the OpenShift or IBM Cloud Pak Platform UI. Settings are described in Table 4.

The following example configures HPA autoscaling in the gateway section of the top-level API Connect CR:

```
spec:
  gateway:
    podAutoScaling:
      hpa:
        maxReplicas: 5
        minReplicas: 3
        targetCPUUtilizationPercentage: 90
        targetMemoryUtilizationPercentage: 80
      method: HPA
```

Table 4. Autoscaling configuration settings

UI Field name / CR Setting	Autoscaling method	Required	Description
• Scaling method • **`method`**	All	Yes	Select the autoscaling method to be used: either **`HPA`** (Horizontal Pod Autoscaling) or **`VPA`** (Vertical Pod Autoscaling). To disable autoscaling, leave **`method`** blank, or omit the **`podAutoScaling:`** section from the CR.
• Minimum pods • **`minReplicas`**	HPA	Yes	Minimum number of pods that can be scaled down to by the horizontal pod autoscaler.
• Maximum pods • **`maxReplicas`**	HPA	Yes	Maximum number of pods that can be scaled up to by the horizontal pod autoscaler. Must be a value greater than **`minReplicas`**.
• Target CPU Utilization Percentage • **`targetCPUUtilizationPercentage:`**	HPA	No	Percent threshold on average CPU usage by pods for triggering horizontal scaling.
• Target Memory Utilization Percentage • **`targetMemoryUtilizationPercentage`**	HPA	No	Percent threshold on average memory usage by pods for triggering horizontal scaling.
• Maximum CPU • **`maxAllowedCPU`**	VPA	No	Maximum value for CPU resource that can be assigned to a DataPower container when scaling vertically. Minimum value is set from **`DataPowerRequestsSpec.ResourceCPU`**
• Maximum Memory • **`maxAllowedMemory`**	VPA	No	Maximum amount of memory that can be assigned to a DataPower container when scaling vertically. Minimum value is set from **`DataPowerRequestsSpec.ResourceMemory`**

Developer Portal subsystem settings

You can specify advanced configuration options for the Developer Portal subsystem directly in the CR or with the Platform UI in Cloud Pak for Integration.

The IBM Cloud Pak Platform UI enables you to specify settings for the following areas:

- Database backups
- Site name

For annotations, labels, node selectors, and tolerations, see Additional Kubernetes settings

Known limitation: When deployed on OpenShift or Cloud Pak for Integration, the API Connect Developer Portal subsystem does not support multiple hosts for the `portalUIEndpoint` endpoint, due to a limitation of Routes in OCP.

Database backups

Table 1. Database backup settings

Field	Type	Description
Credentials	String	For `objstore`, this is the name of your Kubernetes secret that was generated with your username and password for your backup database. For `sftp`, this is the secret that contains the credentials for your `sftp` username and password. Required if configuring backups. See also Configuring portal database backups.
Backup host	String	The S3 endpoint with the corresponding S3 region in the format `<S3endpoint>/<S3region>`. For example: `s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard` For sftp, this is the sftp server host name. Required if configuring backups. See also Configuring portal database backups.
Backup path	String	For `objstore`, the name of your S3 bucket to store backup data. For example: `test-bucket/restore-test`. For sftp, this is the path to the folder on the sftp server. Required if configuring backups. See also Configuring portal database backups.
Backup port	Integer	This is the port for the protocol to connect to the host. There is no default. See also Configuring portal database backups.
Backup protocol	String	Choose the protocol (sftp or objstore) you wish to use to communicate with your remote backup endpoint. Objstore is recommended for most reliability. There is no default. This field must be set to either `sftp` or `objstore` to configure backups. See also Configuring portal database backups.
Backup schedule	String	This is the schedule in cron string format for how often automatic Developer Portal backups are run. For example: `0 /3 * * *` means at minute 0 past every 3rd hour. There is no default. Required if configuring backups. See also Configuring portal database backups.

Site name

Table 2. Site name

Field	Type	Description
Site name	string	Site name is the logical name of the failure domain of this portal subsystem. Typically site name is the name of your data center, such as Amazon AZ. The default is a randomly generated name.

Analytics subsystem settings

Specify advanced configuration settings for the analytics subsystem directly in the analytics CR. If you are using Cloud Pak for Integration, you can configure many of the analytics settings in Platform UI.

Review Analytics preinstallation planning to decide on the deployment options for your analytics subsystem. If you want to offload your analytics data and disable local storage, you must configure local storage disablement before installation because it cannot be changed after installation.

For annotations, labels, node selectors, and tolerations, see Additional Kubernetes settings

Cloud Pak for Integration Platform UI

In the Cloud Pak for Integration Platform UI you can specify settings for:

- Analytics database backup
- Storage type, class, and size

All other analytics settings must be configured directly in the analytics section of the `APIConnectCluster` CR.

Table 1. Database backup

Field	Type	Required	Description
Backup chunk size in GB	Integer	No	`chunkSize` specifies how large files are stored. Large files can be stored as chunks when the snapshot is created. This setting specifies the size of the chunks as GB, MB, or KB. Default value is 1 GB. See Configuring analytics backups.
Credentials	String	No	The backup credential is the name of the Kubernetes secret that you created for accessing your S3-compatible storage. No default. See Configuring analytics backups.
Compress	Boolean: off or on	No	Determines whether metadata files are stored in compressed format. Default value is false (off). See Configuring analytics backups.
Enable server-side encryption	Boolean: off or on	No	Determines whether files are encrypted. When set to true (on), files are encrypted on the server side by using AES256. Default is false (off). See Configuring analytics backups.
Analytics server hostname	String	No	The URL to your S3 storage. No default. See Configuring analytics backups.
Backup Path	String	No	The path to your S3 storage at the URL specified by analytics server hostname.host. No default. See Configuring analytics backups.
Schedule cron expression	String	No	The schedule that determines how often backups are run automatically. The format for the schedule is any valid `cron` string. Default: "*/20 * * * *" See Configuring analytics backups.

Table 2. Storage type, class, and size settings

Field	Type	Required	Description
Master storage class	String	Yes	If you specified dedicated storage, the master storage class is the storage class that is used by your `storage-os-master` pods. Select from the drop down. Local-volume storage is recommended for best performance. If none selected, the default storage class of your cluster is used. See Analytics preinstallation planning.
Shared storage class	String	Yes	The storage class used by your analytics `storage` pods. Select from the drop down. Local-volume storage is recommended for best performance. If none selected, the default storage class of your cluster is used. See Analytics preinstallation planning.
Master volume size	Integer > 0	No	If you specified dedicated storage, then master volume size specifies the disk storage that is allocated to your `storage-os-master` pods. The `storage-os-master` pods do not store your analytics data, and if left unset the value defaults to 5Gi.
Shared volume size	Integer > 0	Yes	How much persistent disk storage is allocated for analytics data (in Gi). See Estimating storage requirements. If you do not have the information to estimate your usage, set this to 500Gi. For an installation where you expect to store little or no analytics data, you can set the storage to 50Gi.
Type	Boolean: dedicated or shared	Yes	OpenSearch storage type to use for your analytics data. For more information about storage types, see Analytics preinstallation planning. The default storage type is shared.

Additional Kubernetes settings

For each API Connect subsystem, you can specify additional settings for annotations and pod management.

The additional settings are generic Kubernetes configuration settings. The Platform UI advanced configuration option for API Connect enables you to set them specifically for each subsystem.

Annotations

The annotations field serves as a pass-through for all the resources managed by the CR. You can add any annotation to this field. The annotations here overwrite the default annotations.

See https://kubernetes.io/docs/concepts/overview/working-with-objects/annotations/.

Labels

The labels field serves as a pass-through for Pod labels. You can add any label to this field and have it apply to the pod. The labels here overwrite the default labels provided. For example, if the label 'mylabel=1' was provided, it would apply to all kubernetes resources managed by this CR.

See https://kubernetes.io/docs/concepts/overview/working-with-objects/labels/.

Node Selector

This field allows you to specify a set of key value pair that must be matched against the node labels to decide which API Connect pods can be scheduled on that node. Only nodes matching all of these key value pairs in their labels will be selected for scheduling API Connect pods.

See https://kubernetes.io/docs/concepts/scheduling-eviction/assign-pod-node/.

Tolerations

This field allows you to select which nodes API Connect pods can be scheduled or not scheduled. By specifying a set of matching tolerations, you can control whether specific nodes can be used for scheduling API Connect Pods.

Effect (optional)
: Effect indicates the taint effect to match. Empty means match all taint effects. When specified, allowed values are NoSchedule, PreferNoSchedule and NoExecute.

Key (optional)
: Key is the taint key that the toleration applies to. Empty means match all taint keys. If the key is empty, operator must be Exists; this combination means to match all values and all keys.

  Operator represents a key's relationship to the value. Valid operators are Exists and Equal. Defaults to Equal. Exists is equivalent to wildcard for value, so that a pod can tolerate all taints of a particular category.

Operator (optional)
: Operator represents a key's relationship to the value. Valid operators are Exists and Equal. Defaults to Equal. Exists is equivalent to wildcard for value, so that a pod can tolerate all taints of a particular category.

Toleration seconds (optional)
: TolerationSeconds represents the period of time the toleration (which must be of effect NoExecute, otherwise this field is ignored) tolerates the taint. By default, it is not set, which means tolerate the taint forever (do not evict). Zero and negative values will be treated as 0 (evict immediately) by the system.

Value (optional)
: Value is the taint value the toleration matches to. If the operator is Exists, the value should be empty, otherwise just a regular string.

See https://kubernetes.io/docs/concepts/scheduling-eviction/taint-and-toleration/.

Configuring timeouts for management endpoints

Adjust the timeout settings for management endpoints by updating the CR.

About this task

On large deployments, or with large API usage, you might encounter timeout issues when deployed with the default timeout setting of 30 seconds. To avoid timeout issues, increase the setting for the management endpoints used in routing.

You do not have to set these values on initial installation. You can set them or change them after installation and reapply the CR YAML files.

Procedure

Edit the CR to set the timeout to 240 seconds.
The instructions for editing depend on whether you install API Connect using subsystem CRs or a single top-level CR:

- If you are installing API Connect using subsystem CRs, edit **`management_CR.yaml`**:

```
  cloudManagerEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: admin.example.com
      secretName: cm-endpoint
  apiManagerEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: manager.example.com
      secretName: apim-endpoint
  platformAPIEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: api.example.com
      secretName: api-endpoint
  consumerAPIEndpoint:
    annotations:
      haproxy.router.openshift.io/timeout: 240s
    hosts:
    - name: consumer.example.com
      secretName: consumer-endpoint
```

- If you are installing API Connect using a top-level CR, the management subsystem settings are embedded in the top-level APIConnectCluster CR. Edit the endpoint settings under `spec:management:` as follows:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-minimum
  name: <name_of_your_instance>
  namespace: ${NAMESPACE}
```

```
spec:
...
  management:
    cloudManagerEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: admin.example.com
        secretName: cm-endpoint
    apiManagerEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: manager.example.com
        secretName: apim-endpoint
    platformAPIEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: api.example.com
        secretName: api-endpoint
    consumerAPIEndpoint:
      annotations:
        haproxy.router.openshift.io/timeout: 240s
      hosts:
      - name: consumer.example.com
        secretName: consumer-endpoint
...
```

Installation procedures with IBM Cloud Pak for Integration

The API Management capability of IBM Cloud Pak for Integration uses API Connect.

There are several methods for installing API Connect with Cloud Pak for Integration:

- Use the Cloud Pak for Integration Platform UI to install API Connect with a top-level CR. The steps are documented in the installation section of the Cloud Pak for Integration documentation: https://www.ibm.com/docs/en/cloud-paks/cp-integration.
- If API Connect is already installed with the top-level CR and you want to migrate it to Cloud Pak for Integration, see Migrating from OpenShift to Cloud Pak for Integration on the same cluster.

Installing API Connect in a single namespace on OpenShift

Use individual subsystem CRs to install API Connect subsystems in a shared namespace on OpenShift.

About this task

API Connect subsystems are installed by creating individual subsystem CRs in the same shared namespace. If you want to install your API Connect subsystems in different namespaces, for example Management server in a namespace that is called **`mgmt`**, and gateway in a namespace that is called **`gway`**, then see: Installing API Connect subsystems in different namespaces or environments on OpenShift.

Air-gapped installations: If you are installing API Connect in an offline environment, first follow the steps for configuring the catalog sources as described here: Air-gapped installation.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

1. Installing operators
   Install operators for API Connect, DataPower, and common services so that you can deploy the API Connect subsystems in a shared namespace on OpenShift.
2. Setting up a certificate issuer
   Create the cert-manager issuer for generating the certificates and secrets for use with API Connect.
3. Installing the management subsystem in a shared namespace
   Install the management subsystem by creating and applying the mgmt_cr.yaml file.
4. Installing the gateway subsystem in a shared namespace
   Install the gateway subsystem by creating and applying the apigateway_cr.yaml file.
5. Installing the portal subsystem in a shared namespace
   Install the portal subsystem by creating and applying the portal_cr.yaml file.
6. Installing the analytics subsystem in a shared namespace
   Install the analytics subsystem by creating and applying the analytics_cr.yaml file.

Installing operators

Install operators for API Connect, DataPower, and common services so that you can deploy the API Connect subsystems in a shared namespace on OpenShift.

Before you begin

The API Connect operator and operand must be at compatible release and fix pack levels. Table 1 lists the current version of the operator and operand for API Connect.

Table 1. API Connect operator and operand versions

API Connect (operand)	Operator channel version	Highest operator version
10.0.8.2-ifix1	v5.4-sc2	5.4.1

If you want to run API Connect operator and subsystems at different versions, the following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
5.4.1	• 10.0.8.2-ifix1 • 10.0.8.1 • 10.0.8.0
5.3.0	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

Procedure

1. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step 3.
   The **ibm-pak** plug-in enables you to access hosted product images, and to run **oc ibm-pak** commands against the cluster. To confirm that **ibm-pak** is installed, run the following command and verify that the response lists the command usage:

   ```
   oc ibm-pak --help
   ```

2. Obtain an entitlement key for the Entitled Registry:
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step 3.
   a. Log in to the IBM Container Library.
   b. In the Container software library, select Get entitlement key.
   c. After the Access your container software heading, click Copy key.
   d. Copy the key to a safe location.
3. Create the namespace where API Connect will be installed, either by selecting Home > Projects > Create Project in the UI, or with the following command:

   ```
   oc create ns <APIC-namespace>
   ```

   The namespace where you install API Connect must meet the following requirements:
   - Red Hat OpenShift: Only one top-level CR (**APIConnectCluster**) can be deployed in each namespace.
   - Cloud Pak for Integration: Only one API Connect capability can be deployed in each namespace.
   - Red Hat OpenShift restricts the use of default namespaces for installing non-cluster services. The following namespaces cannot be used to install API Connect:
     - **default**
     - **kube-system**
     - **kube-public**
     - **openshift-node**
     - **openshift-infra**
     - **openshift**
4. If you are installing the operator into a single namespace, create an OperatorGroup object specifying that namespace.
   Attention: If you are installing the operator into all namespaces, skip this step because the **openshift-operators** namespace already has an appropriate Operator group in place.
   a. Create the apiconnect-operator-group.yaml file with an OperatorGroup object that identifies the namespace in which RBAC permissions for the IBM API Connect Operator will be generated, and where the CSV will be available:

      ```
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: <operator-group-name>
        namespace: <APIC-namespace>
      spec:
        targetNamespaces:
        - <APIC-namespace>
      ```

   b. Apply the OperatorGroup object with the following command:

      ```
      oc apply -f apiconnect-operator-group.yaml
      ```

5. If you are installing the operator in all namespaces, then create the common services namespace:

   ```
   oc create ns ibm-common-services
   ```

6. Create a pull secret in the namespaces where you want to install API Connect.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   a. Open the Red Hat OpenShift web console, click Workloads > Secrets.
   b. Ensure that the Project is set to the namespace where you intend to install API Connect.
   c. Click Create and select Image pull secret.
   d. Set the following parameters for the secret:
      - Set Secret name to **ibm-entitlement-key**.
      - Set Authentication type to **Image registry credentials**.
      - Set Registry server address to **cp.icr.io**.
      - Set Username to **cp**.
      - Set Password to the entitlement key generated in Step 2.

- Click Create to create the secret.

Note: If your Red Hat OpenShift platform is Red Hat OpenShift on IBM Cloud (ROKS), you might need to reload your worker nodes after the image pull secret is created. You can reload the worker nodes either from the Red Hat OpenShift web console or from the command line with the following command: **`ibmcloud oc worker reload`**
For information on using the **`reload`** command, see the Red Hat OpenShift on IBM Cloud documentation.

7. Add the API Connect catalog sources to your cluster.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   Adding catalog sources to your Red Hat OpenShift cluster adds the IBM operators to the list of operators you can install. For most connected and air-gapped clusters, applying individual catalog sources is the most effective way to fully control software versioning on the cluster.

   a. Generate the catalog source files:
      i. Log into your cluster using the **`oc login`** command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use:

      ```
      export CASE_NAME=ibm-apiconnect
      export CASE_VERSION=5.4.1
      export ARCH=amd64
      ```

      For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

      iii. Download the files for the operators required by API Connect:

      ```
      oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
      ```

      iv. Generate the catalog sources for API Connect:

      ```
      oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
      ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

      ```
      cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

   b. Apply the catalog sources:
      i. Apply the catalog sources:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      ii. Confirm that the catalog sources have been created in the **`openshift-marketplace`** namespace:

      ```
      oc get catalogsource -n openshift-marketplace
      ```

8. Add the IBM Cloud Pak foundational services (common services) catalog sources to your cluster.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   a. Generate the catalog source files:
      i. Log into your cluster using the **`oc login`** command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use; substituting the appropriate CASE version:

      ```
      export CASE_NAME=ibm-cp-common-services
      export CASE_VERSION=<case version>
      export ARCH=amd64
      ```

      Set *<case version>* to the value specified for *Foundational services CASE version* in Operator, CASE, and platform requirements, for your deployment type.

      iii. Download the files for the operators required by IBM Cloud Pak foundational services (common services):

      ```
      oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
      ```

      iv. Generate the catalog sources:

      ```
      oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
      ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

      ```
      cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      This command might not return anything if there are no architecture-specific catalog sources.

   b. Apply the catalog sources:
      i. Apply the catalog sources:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      ii. Confirm that the catalog sources have been created in the **`openshift-marketplace`** namespace:

      ```
      oc get catalogsource -n openshift-marketplace
      ```

9. Create the **`apiconnect`** subscription.
   a. Create the **`apiconnect`** subscription with the appropriate channel by creating a file called **`apic-sub.yaml`** and pasting in the following contents, updating the namespace as required:

   ```
   apiVersion: operators.coreos.com/v1alpha1
   kind: Subscription
   ```

```
metadata:
  name: ibm-apiconnect
  namespace: <namespace>
spec:
  channel: v5.4-sc2
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

Where **<namespace>** is one of the following values:

- **openshift-operators** if you are installing the operator in all namespaces
- The namespace created in step 3 if you are installing the operator in a single namespace

b. Apply the subscription with the following command:

```
oc apply -f apic-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as **ibm-apiconnect** or **IBM DataPower Gateway** show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Wait for the **IBM API Connect** and **IBM DataPower Gateway** operators to install.

The **IBM DataPower Gateway** operator is a prerequisite to API Connect and must not be removed.

10. Install cert manager by completing the following steps:
    a. Log in to the OpenShift Container Platform web console.

    b. Navigate to Operators > OperatorHub.

    c. In the filter box, type: **cert-manager Operator for Red Hat OpenShift**.

    d. Select cert-manager Operator for Red Hat OpenShift and click Install.

    e. On the Install Operator page, complete the following steps:
        i. Update the Update channel if needed. The channel defaults to **stable-v1**, which installs the latest stable release of the cert-manager Operator for Red Hat OpenShift.

        ii. Select the Installed Namespace for the operator.
        The default operator namespace is **cert-manager-operator**; if that namespace doesn't exist, it is created for you.

        iii. Select an Update approval strategy:
            - Automatic: allow Operator Lifecycle Manager (OLM) to automatically update the operator when a new version is available.
            - Manual: require a user with the appropriate credentials to approve all operator updates.
        iv. Click Install.
    f. Verify the cert-manager installation by completing the following steps:
        i. Click to Operators > Installed Operators.

        ii. Verify that **cert-manager Operator for Red Hat OpenShift** is listed with a Status of **Succeeded** in the **cert-manager-operator** namespace.

        iii. Verify that cert-manager pods are up and running by running the following command:

        ```
        oc get pods -n cert-manager
        ```

        For a successful installation, the response looks like the following example:

        ```
        NAME                                       READY   STATUS    RESTARTS   AGE
        cert-manager-bd7fbb9fc-wvbbt               1/1     Running   0          3m39s
        cert-manager-cainjector-56cc5f9868-7g9z7   1/1     Running   0          4m5s
        cert-manager-webhook-d4f79d7f7-9dg9w       1/1     Running   0          4m9s
        ```

11. Create the **ibm-common-services-operator** subscription, if it does not already exist.
    a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: <namespace>
spec:
  channel: v4.6
  name: ibm-common-service-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

Where: **<namespace>** is one of the following values:

- **openshift-operators** if you are installing the operator in all namespaces
- The namespace created in step 3 if you are installing the operator in a single namespace

b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as **ibm-apiconnect**, **IBM Cloud Pak foundational services**, or **Operand Deployment Lifecycle Manager** show the status of "Upgrade available", approve the upgrade by completing the following

steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the `ibm-common-services` namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the `IBM Cloud Pak foundational services` and `Operand Deployment Lifecycle Manager` operators to install.

Next topic: Setting up a certificate issuer

Setting up a certificate issuer

Create the cert-manager issuer for generating the certificates and secrets for use with API Connect.

Before you begin

To deploy API Connect, you must first create the cert-manager issuers and certificates that API Connect uses. On OpenShift cert-manager is bundled as a foundational service, so you do not need to install cert-manager itself. For more information on cert-manager: Key Concepts: Cert-manager, Issuers, and Secrets

Procedure

1. Create a file that is called `ingress-issuer-v1.yaml` and paste in the following contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.

      app.kubernetes.io/managed-by: "ibm-apiconnect"
      app.kubernetes.io/name: "gateway-peering"
```

2. Apply the file to your namespace with `oc apply -f ingress-issuer-v1.yaml -n <apic_namespace>`
3. Verify that the command installation succeeded by running the following command:

   `oc get certificates -n <apic_namespace>`

   All certificates created successfully:

```
NAME                          READY   SECRET                        AGE
analytics-ingestion-client    True    analytics-ingestion-client    70s
gateway-client-client         True    gateway-client-client         69s
gateway-peering               True    gateway-peering               69s
gateway-service               True    gateway-service               69s
ingress-ca                    True    ingress-ca                    71s
portal-admin-client           True    portal-admin-client           71s
```

Previous topic: Installing operators
Next topic: Installing the management subsystem in a shared namespace

Installing the management subsystem in a shared namespace

Install the management subsystem by creating and applying the mgmt_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Use the OpenShift CLI to edit the custom resource template for the management subsystem then apply the resource. Verify that the pods are up and running, and validate that you can connect to the API Connect Cloud Manager.

Procedure

1. Create a file that is called mgmt_cr.yaml and paste in the following content:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  name: management
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: management
  annotations:
    apiconnect-operator/cp4i: "false"
spec:
  version: $APP_PRODUCT_VERSION
  profile: $PROFILE
  portal:
    admin:
      secretName: portal-admin-client
  analytics:
    ingestion:
      secretName: analytics-ingestion-client
  gateway:
    client:
      secretName: gateway-client-client
  cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: admin.$STACK_HOST
      secretName: cm-endpoint
  apiManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: manager.$STACK_HOST
      secretName: apim-endpoint
  platformAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: api.$STACK_HOST
      secretName: api-endpoint
  consumerAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: consumer.$STACK_HOST
      secretName: consumer-endpoint
  consumerCatalogEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: consumer-catalog.myhost.subnet.example.com
      secretName: consumer-catalog-endpoint
  databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
```

```
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the YAML file and replace the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.8.2-ifix1

$PROFILE
Specify your management subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress host names to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
cloudManagerEndpoint:
      < ... >
    hosts:
    - name: admin.myhost.subnet.example.com
      secretName: cm-endpoint

  apiManagerEndpoint:
      < ... >
    hosts:
    - name: manager.myhost.subnet.example.com
      secretName: apim-endpoint

  platformAPIEndpoint:
      < ... >
    hosts:
    - name: api.myhost.subnet.example.com
      secretName: api-endpoint

  consumerAPIEndpoint:
      < ... >
    hosts:
    - name: consumer.myhost.subnet.example.com
      secretName: consumer-endpoint

  consumerCatalogEndpoint:
      < ... >
    hosts:
    - name: consumer-catalog.myhost.subnet.example.com
      secretName: consumer-catalog-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **cloudManagerEndpoint**, you can replace **admin.$STACK_HOST** with **my.cloudmgr.myhost.subnet.example.com**, where **my.cloudmgr** replaces **admin**, and **myhost.subnet.example.com** replaces **STACK_HOST**. For example:

```
cloudManagerEndpoint:
      < ... >
    hosts:
    - name: my.cloudmgr.myhost.subnet.example.com
      secretName: cm-endpoint
```

  You can do this for some or all of the host names, depending on your customization requirements.

$STORAGE_CLASS
The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

```
storageClassName: local-storage
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.
$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.
$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Install the management subsystem by applying the modified CR with the following command:

```
oc apply -f mgmt_cr.yaml -n <management_namespace>
```

4. Verify that the management subsystem is fully installed by running the following command:

```
oc get ManagementCluster -n <management_namespace>
```

The installation is complete when the **READY** status is **True**, and the **SUMMARY** reports that all services are online:

```
NAME          READY   SUMMARY   VERSION    RECONCILED VERSION   AGE
management    True    16/16      <version>   <version-build>      7m17s
```

5. Verify that you can log in to the API Connect Cloud Manager UI:
   a. Determine the URL for the Cloud Manager UI by running the following command to view the API Connect endpoints:

      ```
      oc get routes -n <management_namespace>
      ```

   b. Locate the `management-admin` endpoint, and note it down.
   c. Determine the Cloud Manager administrator password by running the following commands:

      ```
      oc get secret -n <management-namespace> | grep management-admin-secret

      oc get secret -n <management-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -
      d && echo ""
      ```

   d. Open a browser and go to the `management-admin-apic` endpoint.
   e. Log in to the Cloud Manager as `admin` with the administrator password.
6. Store all secrets and passwords in a safe place.
7. Backup your management subsystem database and infrastructure configuration: Backing up and restoring the management subsystem.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Setting up a certificate issuer
Next topic: Installing the gateway subsystem in a shared namespace

Installing the gateway subsystem in a shared namespace

Install the gateway subsystem by creating and applying the apigateway_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Important: When you install the gateway subsystem, you must configure the gateway subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Use the OpenShift CLI to edit the custom resource template for the gateway, apply the resource, verify that the pods are up and running.

Procedure

1. Create the gateway admin secret with: `oc -n <gateway namespace> create secret generic admin-secret --from-literal=password=admin`
2. If you are installing the API Gateway (v6), create a yaml file that is called `apigateway_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.

    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  tokenManagementService:
    enabled: true
    storage:
      storageClassName: $STORAGE_CLASS
      volumeSize: 30Gi
  adminUser:
    secretName: admin-secret
  mtlsValidateClient: true
  # syslogConfig:
  #   enabled: false # if true, provide below details
  #   remoteHost: $DATAPOWER_SYSLOG_TCP_REMOTE_HOST # must be a string
  #   remotePort: $DATAPOWER_SYSLOG_TCP_REMOTE_PORT # must be an int
  #   secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

If you are installing the v5 gateway, create a yaml file that is called v5gateway_cr.yaml and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: gateway.apiconnect.ibm.com/v1beta1
kind: GatewayCluster
metadata:
  name: gwv5
  labels:
    app.kubernetes.io/instance: gateway
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: gwv5
spec:
  version: $APP_PRODUCT_VERSION
  profile: $PROFILE
  apicGatewayServiceV5CompatibilityMode: true
  gatewayEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: gw.$STACK_HOST
      secretName: gwv5-endpoint
  gatewayManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: gwd.$STACK_HOST
      secretName: gwv5-manager-endpoint
  apicGatewayServiceTLS:
    secretName: gateway-service
  apicGatewayPeeringTLS:
    secretName: gateway-peering
  datapowerLogLevel: 3
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  adminUser:
    secretName: admin-secret
  mtlsValidateClient: true
  # syslogConfig:
  #   enabled: false # if true, provide below details
```

```
  #   remoteHost: $DATAPOWER_SYSLOG_TCP_REMOTE_HOST # must be a string
  #   remotePort: $DATAPOWER_SYSLOG_TCP_REMOTE_PORT # must be an int
  #   secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

3. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.8.2-ifix1

$PROFILE
Specify your gateway subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
gatewayEndpoint:
      < ... >
    hosts:
    - name: rgw.myhost.subnet.example.com
      secret: gwv6-endpoint

  gatewayManagerEndpoint:
       < ... >
    hosts:
    - name: rgwd.myhost.subnet.example.com
      secret: gwv6-manager-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **gatewayEndpoint**, you can replace **rgw.$STACK_HOST** with **my.gateway.endpoint.myhost.subnet.example.com**, where **my.gateway.endpoint** replaces **rgw**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

```
gatewayEndpoint:
       < ... >
    hosts:
    - name: my.gateway.endpoint.myhost.subnet.example.com
      secret: gwv6-endpoint
```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

```
storageClassName: local-storage
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.
$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.
$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

syslogConfig
To enable this feature uncomment this section, set **enabled: true**, and set the properties:
$DATAPOWER_SYSLOG_TCP_REMOTE_HOST
remoteHost: <*remote.host*>
String. The hostname of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_REMOTE_PORT
remotePort: <*remote_port_number*>
Integer. The port number of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_TLS_SECRET
secretName: <*secret*>
String. The TLS secret name of the server for **syslogConfig**.

4. Optional: If applicable to your deployment, update the gateway CR file to configure **DataPowerService** APIs to customize your DataPower deployment. See Customizing a DataPower deployment.
5. Optional: If you want to enable JWT security for communications between the management and gateway, add and set the property **jwksUrl**, and set **spec.mtlsValidateClient** to false.

```
spec:
  ...
  jwksUrl: <JWKS URL>
  mtlsValidateClient: false
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.

6. Optional: Update the gateway CR file to enable autoscaling of gateway pods to ensure high availability of DataPower pods. See Enabling autoscaling of gateway pods.
7. Install the gateway Custom Resource by applying the yaml file:
   For a DataPower® API Gateway, run the following command:

   ```
   oc apply -f apigateway_cr.yaml -n <namespace>
   ```

   For a DataPower Gateway (v5 compatible), run the following command:

   ```
   oc apply -f v5cgateway_cr.yaml -n <namespace>
   ```

8. To verify that the gateway subsystem is fully installed, run the following command:

   ```
   oc get GatewayCluster -n <namespace>
   ```

   The installation is complete when the **READY** status is **True**, and the **SUMMARY** reports that all services are online (**2/2**) for all the gateway subsystems that were installed. Example:

   ```
   NAME    READY    SUMMARY    VERSION     RECONCILED VERSION    AGE
   gwv6    True     2/2        <version>   <version-build>       7m32s
   ```

   There is no need to wait for the **READY** status to be **True** before moving on to next Subsystem installation.
9. Verify that the gateway is ready to be registered with the Management subsystem by calling the **health** api on the **gatewayManagerEndpoint.hosts.name** defined in your yaml file: **https://gwd.$STACK_HOST/health**.

   ```
   curl -k https://gwd.example.com/health
   {"status":"ok"}
   ```

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the management subsystem in a shared namespace
Next topic: Installing the portal subsystem in a shared namespace

Installing the portal subsystem in a shared namespace

Install the portal subsystem by creating and applying the portal_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Important: When you install the portal subsystem, you must configure the portal subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Use the OpenShift CLI to edit the custom resource template for the portal subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called **portal_cr.yaml** and paste in these contents:

   ```
   #
   # Licensed under the Apache License, Version 2.0 (the "License");
   # you may not use this file except in compliance with the License.
   # You may obtain a copy of the License at
   #
   #     http://www.apache.org/licenses/LICENSE-2.0
   #
   # Unless required by applicable law or agreed to in writing, software
   # distributed under the License is distributed on an "AS IS" BASIS,
   # WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
   # See the License for the specific language governing permissions and
   # limitations under the License.
   #
   ```

```
apiVersion: portal.apiconnect.ibm.com/v1beta1

    secretName: management-ca
  portalAdminEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: api.portal.$STACK_HOST
      secretName: portal-admin
  portalUIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: portal.$STACK_HOST
      secretName: portal-web
  databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
  databaseLogsVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 12Gi
  webVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
  backupVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 120Gi
  adminVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 20Gi
  certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
  adminClientSubjectDN: CN=portal-admin-client,O=cert-manager
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the yaml file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.8.2-ifix1

$PROFILE
Specify your portal subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when you specify endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, for a subdomain of **myhost.subnet.example.com**:

```
portalAdminEndpoint:
    < ... >
    hosts:
    - name: api.portal.myhost.subnet.example.com
      secret: portal-admin

  portalUIEndpoint:
    < ... >
    hosts:
    - name: portal.myhost.subnet.example.com
      secret: portal-web
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, for **portalAdminEndpoint**, you can replace **api.portal.$STACK_HOST** with **my.api.portal.myhost.subnet.example.com**, where **my.api.portal** replaces **api.portal**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

  ```
  portalAdminEndpoint:
        < ... >
    hosts:
    - name: my.api.portal.myhost.subnet.example.com
      secret: cm-endpoint
  ```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
: The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**. For example, for local storage:

  ```
  databaseVolumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
      volumeSize: 200Gi
  databaseLogsVolumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
      volumeSize: 12Gi
  webVolumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
      volumeSize: 200Gi
  backupVolumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
      volumeSize: 300Gi
  adminVolumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
      volumeSize: 20Gi
  certVolumeClaimTemplate:
      storageClassName: $STORAGE_CLASS
      volumeSize: 4Gi
  ```

  Note:
  - The **databaseVolumeClaimTemplate** has a minimum value of 30Gi. The **webVolumeClaimTemplate** has a minimum value of 20Gi. The **backupVolumeClaimTemplate** has a minimum value of 30Gi. However, all three need to be sized according to the installation. For more information on planning your portal PV requirements, see Portal subsystem.
  - The **adminVolumeClaimTemplate** and **databaseLogsVolumeClaimTemplate** in this example have their minimum values and you do not need to change them.
  - The **certVolumeClaimTemplate** is used by the nginx pod and in 2DCDR mode it is also by the **tunnel**, **db-remote** and **www-remote** pods. It can be sized small, just like the **adminVolumeClaimTemplate**, and does not need to be increased based on the number of sites.

$LICENSE_ACCEPTANCE
: Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
: Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
: Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you want to disable mTLS for communications between the management and portal, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

   ```
   spec:
     ...
     mtlsValidateClient: false
     jwksUrl: <JWKS URL>
   ```

   where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

   ```
   kubectl describe mgmt -n <namespace>
   ...
   status:
     - name: jwksUrl
       secretName: api-endpoint
       type: API
       uri: https://api.apic.acme.com/api/cloud/oauth2/certs
   ```

   For more information about JWT security, see Enable JWT security instead of mTLS.
4. Install the portal subsystem by applying the modified CR with the following command:

   ```
   oc apply -f portal_cr.yaml -n <namespace>
   ```

5. Verify that the portal subsystem is fully installed:

   ```
   oc get PortalCluster -n <namespace>
   ```

   The installation is complete when **STATUS** reports **Running**, **Ready** reports that all services are online (**3/3**), and **MESSAGE** reports "Ready for API Cloud Manager service registration", for example:

   ```
   NAME           READY   STATUS    VERSION     RECONCILED VERSION   MESSAGE                                    AGE
   portal         3/3     Running   <version>   <version>            Ready for API Cloud Manager service registration   2h
   ```

   You do not need to wait for the portal installation to complete before you move on to the next subsystem installation.
6. Verify that you can access the portal web endpoint by browsing to the **portalUIEndpoint.hosts.name** as configured in your yaml file:

   ```
   curl -k https://portal.$STACK_HOST
   <!DOCTYPE html>
   <html>
   ```

```
<head>
<title>Developer Portal is ready to create sites!</title>
<style>
    body {
        width: 35em;
        margin: 0 auto;
        font-family: Tahoma, Verdana, Arial, sans-serif;
    }
</style>
</head>
<body>Developer Portal is ready to create sites!</h1>
<p>If you see this page, the web server is successfully installed and
working. Further configuration is required.</p>
</body>
</html>
```

7. It is highly recommend that you retain the portal subsystem encryption secret in a safe location, in case you need to restore the portal subsystem during a disaster recovery scenario.
   The encryption secret is created when the portal subsystem is initially deployed. You can obtain the name of the encryption secret from the portal subsystem custom resource after the installation is complete:

   a. Obtain the name of the encryptionSecret:

   ```
   oc get ptl portal -o yaml -n <namespace> | grep encryptionSecret
   encryptionSecret: portal-enc-key
   ```

   The name of encryption secret is **portal-enc-key**.

   b. Save the secret yaml in a safe location:

   ```
   oc get secret portal-enc-key -o yaml -n <namespace> > portal-enc-key.yaml
   ```

8. Backup the portal installation. See Backing up and restoring the developer portal.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the gateway subsystem in a shared namespace
Next topic: Installing the analytics subsystem in a shared namespace

Installing the analytics subsystem in a shared namespace

Install the analytics subsystem by creating and applying the analytics_cr.yaml file.

Before you begin

Complete the following tasks to prepare for deploying API Connect:

1. Preparing for installation
2. Installing operators
3. Setting up a certificate issuer

About this task

Important: When you install the analytics subsystem, you must configure the analytics subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
Use the OpenShift CLI to edit the custom resource template for the analytics subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called **analytics_cr.yaml** and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsCluster
metadata:
```

```
  name: analytics
  labels:
    app.kubernetes.io/instance: analytics
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: analytics
annotations:
    apiconnect-operator/cp4i: "false"
spec:
  version: $APP_PRODUCT_VERSION
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  profile: $PROFILE
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  ingestion:
    endpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: ai.$STACK_HOST
        secretName: analytics-ai-endpoint
    clientSubjectDN: CN=analytics-ingestion-client,O=cert-manager
  storage:
    type: $STORAGE_TYPE
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
   #master: # uncomment this section if you set storage.type = dedicated.
   #  volumeClaimTemplate:
   #    storageClassName: $STORAGE_CLASS
```

2. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

`version: <version_number>`

Example version number: 10.0.8.2-ifix1

$PROFILE
Specify your analytics subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.
Note: The profile that you select influences your storage type options. If you select an **n1** profile then you must select the **shared** storage type. For more information about storage types, see storage types.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can customize the subdomain or the complete hostname:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** with the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
  ingestion:
    endpoint:
       < ... >
      hosts:
      - name: ai.myhost.subnet.example.com
        secret: analytics-ai-endpoint
       < .... >
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, you can replace **$STACK_HOST** with **my.analytics.ingestion.myhost.subnet.example.com**, where **my.analytics.ingestion** replaces **ai**, and **myhost.subnet.example.com** replaces **STACK_HOST**.

```
ingestion:
    endpoint:
      < ... >
      hosts:
      - name: my.analytics.ingestion.myhost.subnet.example.com
        secret: analytics-ai-endpoint
       < ... >
```

$STORAGE_TYPE
If you set **$PROFILE** to an **n1** (one replica) profile, then set this to **shared**. If you set **$PROFILE** to an **n3** (three replica) profile then set this to **dedicated** and uncomment the **storage.master** section, for example:

```
  storage:
    type: dedicated
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
    master:
```

```
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
```

For more information about storage types, see dedicated or shared storage.

`$STORAGE_CLASS`
The Kubernetes storage class to be used for persistent volume claims. For more information, see Analytics preinstallation planning. Find the available storage classes in the target cluster by running the following command: `oc get sc`. Example:

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
```

$DATA_VOLUME_SIZE
Size of storage allocated for data. To estimate the storage space you require, see Estimating storage requirements. If you are unable to estimate your storage requirement then set it to 500Gi.

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
        volumeSize: 500Gi
```

`$LICENSE_ACCEPTANCE`
Set `accept` to `true`. You must accept the license to successfully deploy API Connect.
`$LICENSE_USE`
Set `use` to either `production` or `nonproduction` to match the license that you purchased.
$LICENSE_ID
Set `license:` to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you want to disable mTLS for communications between the management and analytics subsystem, and between the gateway and analytics subsystem, and enable JWT instead, then add and set the properties `mtlsValidateClient` and `jwksUrl`.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the `jwksUrl`, describe the management CR and check the `status:` section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow.
4. Optional: If you plan to configure analytics database backups, then define the storage that is required for backups:
Define your backup PVC by adding the `backup.volumeClaimTemplate` property in `spec.storage`. For example:

```
spec:
  storage:
    backup:
      volumeClaimTemplate:
        storageClassName: <storage class>
        volumeSize: <size>
```

If you are not sure of the volume size that you need, then you can configure the `backup.volumeClaimTemplate` after installation.

5. Install the analytics subsystem by applying the modified CR with the following command:

```
oc apply -f analytics_cr.yaml -n <namespace>
```

6. Verify that the analytics subsystem is fully installed:

```
oc get AnalyticsCluster -n <namespace>
```

The installation is complete when `READY` shows all pods running (`n/n`), and the `STATUS` reports `Running`. Example:

```
NAME         READY   STATUS    VERSION          RECONCILED VERSION   AGE
analytics    n/n     Running   10.0.8.0   10.0.8.0-1281    86m
```

It is not necessary to wait for analytics installation to complete before you move on to the next subsystem installation.

7. Backup your analytics subsystem and configure scheduled analytics database backups: Backing up and restoring the analytics subsystem.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the portal subsystem in a shared namespace

Installing API Connect subsystems in different namespaces or environments on OpenShift

Install API Connect subsystems in different namespaces, for example Management subsystem in a namespace that is called **`apicmgmt`**, Gateway in a namespace called **`apicgway`**. These same steps can also be used for installing subsystems in different environments.

About this task

Install API Connect subsystems where you have separate namespaces for each subsystem. There are two main ways to achieve this:

- Installing the API Connect operator with global scope - This document provides you further information on this approach to install API Connect subsystems.
- Setting up multiple namespaces with separate API Connect operators - You can set up multiple namespaces, each with its own API Connect operator. When you install multiple operators in different namespaces, make sure all of them are the same version. You can use different versions only during an upgrade, but aim to upgrade the operators together or as close to each other as possible.
  The API Connect operator pods in your operator namespace must have network access to the namespace where your API Connect subsystems are installed. Do not configure OpenShift network policies that block communication between any of these namespaces:
  - API Connect operator
  - API Connect subsystems (operands)
  - cert-manager
  - openshift-operator-lifecycle-manager
  - ibm-common-services

  For more information, see Installing operators.

  For information about single namespace installation, see Installing API Connect in a single namespace on OpenShift.

Air-gapped installations: If you are installing API Connect in an offline environment, first follow the steps for configuring the catalog sources as described here: Air-gapped installation.

Attention: If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.

1. Installing operators
   Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect subsystems across multiple namespaces on Red Hat OpenShift. If you deploy API Connect subsystems in different environments, then the corresponding operator must be installed in each environment; for example, install the DataPower operator in your Gateway environment, and the API Connect operator in your Portal environment.
2. Installing the management subsystem
   Install the managment subsystem by creating and applying the **`ingress-issuer`** and **`mgmt_cr`** YAML files.
3. Extracting the management ingress-ca certificates
   In order for the management subsystem to be able to communicate with subsystems in different namespaces, these subsystems need to have the same ingress-ca certificates as the management subsystem.
4. Installing the gateway subsystem
   Install the gateway subsystem by creating and applying the ingress-ca, common-issuer, gateway-certs and gateway_cr yaml files.
5. Installing the portal subsystem
   Install the portal subsystem by creating and applying the ingress-ca, common-issuer, and portal_cr yaml files.
6. Installing the analytics subsystem
   Install the analytics subsystem by creating and applying the ingress-ca, common-issuer, and analytics_cr yaml files.

Installing operators

Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect subsystems across multiple namespaces on Red Hat OpenShift. If you deploy API Connect subsystems in different environments, then the corresponding operator must be installed in each environment; for example, install the DataPower operator in your Gateway environment, and the API Connect operator in your Portal environment.

Before you begin

The API Connect operator and operand must be at compatible release and fix pack levels. Table 1 lists the current version of the operator and operand for API Connect.

Table 1. API Connect operator and operand versions

API Connect (operand)	Operator channel version	Highest operator version
10.0.8.2-ifix1	v5.4-sc2	5.4.1

If you want to run API Connect operator and subsystems at different versions, the following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
5.4.1	• 10.0.8.2-ifix1 • 10.0.8.1 • 10.0.8.0
5.3.0	• 10.0.8.1 • 10.0.8.0

API Connect Operator version	API Connect version
5.2.0	• 10.0.8.0

Procedure

1. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step #inst_ocp_cp4i_ops_subs__d290e254.
   The **ibm-pak** plug-in enables you to access hosted product images, and to run **oc ibm-pak** commands against the cluster. To confirm that **ibm-pak** is installed, run the following command and verify that the response lists the command usage:

   ```
   oc ibm-pak --help
   ```

2. Obtain an entitlement key for the Entitled Registry:
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step #inst_ocp_cp4i_ops_subs__d290e254.
   a. Log in to the IBM Container Library.
   b. In the Container software library, select Get entitlement key.
   c. After the Access your container software heading, click Copy key.
   d. Copy the key to a safe location.
3. Create a pull secret in the namespaces where you want to install API Connect.
   a. Open the Red Hat OpenShift web console, click Workloads > Secrets.
   b. Ensure that the Project is set to the namespace where you intend to install API Connect.
   c. Click Create and select Image pull secret.
   d. Set the following parameters for the secret:
      - Set Secret name to **ibm-entitlement-key**.
      - Set Authentication type to **Image registry credentials**.
      - Set Registry server address to **cp.icr.io**.
      - Set Username to **cp**.
      - Set Password to the entitlement key generated in Step 2.
      - Click Create to create the secret.

   Note: If your Red Hat OpenShift platform is Red Hat OpenShift on IBM Cloud (ROKS), you might need to reload your worker nodes after the image pull secret is created. You can reload the worker nodes either from the Red Hat OpenShift web console or from the command line with: **ibmcloud oc worker reload**. For information on using the **reload** command, see the Red Hat OpenShift on IBM Cloud documentation.
4. Add the API Connect catalog sources to your cluster.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   Adding catalog sources to your Red Hat OpenShift cluster adds the IBM operators to the list of operators you can install. For most connected and air-gapped clusters, applying individual catalog sources is the most effective way to fully control software versioning on the cluster.

   a. Generate the catalog source files:
      i. Log into your cluster using the **oc login** command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use:

      ```
      export CASE_NAME=ibm-apiconnect
      export CASE_VERSION=5.4.1
      export ARCH=amd64
      ```

      For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

      iii. Download the files for the operators required by API Connect:

      ```
      oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
      ```

      iv. Generate the catalog sources for API Connect:

      ```
      oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
      ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

      ```
      cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

   b. Apply the catalog sources:
      i. Apply the catalog sources:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      ii. Confirm that the catalog sources have been created in the **openshift-marketplace** namespace:

      ```
      oc get catalogsource -n openshift-marketplace
      ```

5. Add the IBM Cloud Pak foundational services (common services) catalog sources to your cluster.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   a. Generate the catalog source files:
      i. Log into your cluster using the **oc login** command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use; substituting the appropriate CASE version:

```
export CASE_NAME=ibm-cp-common-services
export CASE_VERSION=<case version>
export ARCH=amd64
```

Set *<case version>* to the value specified for *Foundational services CASE version* in Operator, CASE, and platform requirements, for your deployment type.

iii. Download the files for the operators required by IBM Cloud Pak foundational services (common services):

```
oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
```

iv. Generate the catalog sources:

```
oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
```

v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

This command might not return anything if there are no architecture-specific catalog sources.

b. Apply the catalog sources:

i. Apply the catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

ii. Confirm that the catalog sources have been created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

6. Create the `apiconnect` subscription.

a. Create the `apiconnect` subscription with the appropriate channel by creating a file called `apic-sub.yaml` and pasting in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-apiconnect
  namespace: openshift-operators
spec:
  channel: v5.4-sc2
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

b. Apply the subscription with the following command:

```
oc apply -f apic-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as `ibm-apiconnect` or `IBM DataPower Gateway` show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Wait for the `IBM API Connect` and `IBM DataPower Gateway` operators to install.

The `IBM DataPower Gateway` operator is a prerequisite to API Connect and must not be removed.

7. Install cert manager by completing the following steps:

a. Log in to the OpenShift Container Platform web console.

b. Navigate to Operators > OperatorHub.

c. In the filter box, type: `cert-manager Operator for Red Hat OpenShift`.

d. Select cert-manager Operator for Red Hat OpenShift and click Install.

e. On the Install Operator page, complete the following steps:

i. Update the Update channel if needed. The channel defaults to `stable-v1`, which installs the latest stable release of the cert-manager Operator for Red Hat OpenShift.

ii. Select the Installed Namespace for the operator.
The default operator namespace is `cert-manager-operator`; if that namespace doesn't exist, it is created for you.

iii. Select an Update approval strategy:
- Automatic: allow Operator Lifecycle Manager (OLM) to automatically update the operator when a new version is available.
- Manual: require a user with the appropriate credentials to approve all operator updates.

iv. Click Install.

f. Verify the cert-manager installation by completing the following steps:

i. Click to Operators > Installed Operators.

ii. Verify that `cert-manager Operator for Red Hat OpenShift` is listed with a Status of `Succeeded` in the `cert-manager-operator` namespace.

iii. Verify that cert-manager pods are up and running by running the following command:

```
oc get pods -n cert-manager
```

For a successful installation, the response looks like the following example:

```
NAME                                      READY   STATUS    RESTARTS   AGE
cert-manager-bd7fbb9fc-wvbbt              1/1     Running   0          3m39s
cert-manager-cainjector-56cc5f9868-7g9z7  1/1     Running   0          4m5s
cert-manager-webhook-d4f79d7f7-9dg9w      1/1     Running   0          4m9s
```

8. Create the **ibm-common-services-operator** subscription, if it does not already exist.
   a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: openshift-operators
spec:
  channel: v4.6
  name: ibm-common-service-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

   b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

   c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
   If any operators such as **ibm-apiconnect**, **IBM Cloud Pak foundational services**, or **Operand Deployment Lifecycle Manager** show the status of "Upgrade available", approve the upgrade by completing the following steps:

      i. Click Upgrade available.
      ii. Click Preview InstallPlan.
      iii. Click Approve.
      iv. Check the **ibm-common-services** namespace and ensure that all operators with a status of "Upgrade available" are approved.
      v. Wait for the **IBM Cloud Pak foundational services** and **Operand Deployment Lifecycle Manager** operators to install.

9. Create the namespaces for your API Connect subsystems either by selecting Project > Create Project in the UI, or with the command:

```
oc create ns <APIC-namespace>
```

Note: Red Hat OpenShift restricts the use of default namespaces for installing non-cluster services. The following namespaces cannot be used to install API Connect:

- **default**
- **kube-system**
- **kube-public**
- **openshift-node**
- **openshift-infra**
- **openshift**

What to do next

Proceed to install the API Connect subsystems as explained in: Installing the management subsystem

Next topic: Installing the management subsystem

Installing the management subsystem

Install the managment subsystem by creating and applying the **ingress-issuer** and **mgmt_cr** YAML files.

Before you begin

When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Create a file called **ingress-issuer-management.yaml** and paste in the following:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
```

```
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: selfsigning-issuer
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:

  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

2. Apply the YAML file with: `oc apply -f ingress-issuer-management.yaml -n <management namespace>`
3. Confirm that the issuers were created and are in ready state:

```
oc get issuers -n <management namespace>
NAME                READY
ingress-issuer      True
selfsigning-issuer  True
```

Procedure

1. Create a file that is called mgmt_cr.yaml and paste in the following content:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  name: management
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: management
  annotations:
    apiconnect-operator/cp4i: "false"
spec:
  version: $APP_PRODUCT_VERSION
  profile: $PROFILE
  portal:
    admin:
      secretName: portal-admin-client
  analytics:
    ingestion:
      secretName: analytics-ingestion-client
  gateway:
    client:
      secretName: gateway-client-client
  cloudManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: admin.$STACK_HOST
      secretName: cm-endpoint
  apiManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: manager.$STACK_HOST
      secretName: apim-endpoint
  platformAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: api.$STACK_HOST
      secretName: api-endpoint
  consumerAPIEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
```

```
    hosts:
    - name: consumer.$STACK_HOST
      secretName: consumer-endpoint
  consumerCatalogEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
    hosts:
    - name: consumer-catalog.myhost.subnet.example.com
      secretName: consumer-catalog-endpoint
  databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the YAML file and replace the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.8.2-ifix1

$PROFILE
Specify your management subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress host names to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

  ```
  cloudManagerEndpoint:
        < ... >
    hosts:
    - name: admin.myhost.subnet.example.com
      secretName: cm-endpoint

  apiManagerEndpoint:
        < ... >
    hosts:
    - name: manager.myhost.subnet.example.com
      secretName: apim-endpoint

  platformAPIEndpoint:
        < ... >
    hosts:
    - name: api.myhost.subnet.example.com
      secretName: api-endpoint

  consumerAPIEndpoint:
        < ... >
    hosts:
    - name: consumer.myhost.subnet.example.com
      secretName: consumer-endpoint
  ```

  ```
  consumerCatalogEndpoint:
        < ... >
    hosts:
    - name: consumer-catalog.myhost.subnet.example.com
      secretName: consumer-catalog-endpoint
  ```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **cloudManagerEndpoint**, you can replace **admin.$STACK_HOST** with **my.cloudmgr.myhost.subnet.example.com**, where **my.cloudmgr** replaces **admin**, and **myhost.subnet.example.com** replaces **STACK_HOST**. For example:

  ```
  cloudManagerEndpoint:
        < ... >
    hosts:
    - name: my.cloudmgr.myhost.subnet.example.com
      secretName: cm-endpoint
  ```

  You can do this for some or all of the host names, depending on your customization requirements.

$STORAGE_CLASS
The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

```
storageClassName: local-storage
```

$LICENSE_ACCEPTANCE

Set `accept` to `true`. You must accept the license to successfully deploy API Connect.

`$LICENSE_USE`

Set `use` to either `production` or `nonproduction` to match the license that you purchased.

$LICENSE_ID

Set `license:` to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Install the management subsystem by applying the modified CR with the following command:

```
oc apply -f mgmt_cr.yaml -n <management_namespace>
```

4. Verify that the management subsystem is fully installed by running the following command:

```
oc get ManagementCluster -n <management_namespace>
```

The installation is complete when the `READY` status is `True`, and the `SUMMARY` reports that all services are online:

```
NAME          READY   SUMMARY    VERSION     RECONCILED VERSION    AGE
management    True    16/16       <version>    <version-build>       7m17s
```

5. Verify that you can log in to the API Connect Cloud Manager UI:
   a. Determine the URL for the Cloud Manager UI by running the following command to view the API Connect endpoints:

   ```
   oc get routes -n <management_namespace>
   ```

   b. Locate the `management-admin` endpoint, and note it down.
   c. Determine the Cloud Manager administrator password by running the following commands:

   ```
   oc get secret -n <management-namespace> | grep management-admin-secret

   oc get secret -n <management-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -
   d && echo ""
   ```

   d. Open a browser and go to the `management-admin-apic` endpoint.
   e. Log in to the Cloud Manager as `admin` with the administrator password.
6. Store all secrets and passwords in a safe place.
7. Backup your management subsystem database and infrastructure configuration: Backing up and restoring the management subsystem.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing operators
Next topic: Extracting the management ingress-ca certificates

Extracting the management ingress-ca certificates

In order for the management subsystem to be able to communicate with subsystems in different namespaces, these subsystems need to have the same ingress-ca certificates as the management subsystem.

About this task

This task describes how to extract the ingress-ca certificates to a yaml file, ready for applying to the subsystems that are in different namespaces.

Procedure

1. Export the ingress-ca secret to a yaml file with: `oc -n <management namespace> get secret ingress-ca -o yaml > ingress-ca.yaml`
2. Edit the ingress-ca.yaml file and remove the following properties: metadata.creationTimestamp, metadata.namespace,metadata.resourceVersion, metadata.uid, metadata.selfLink
3. Keep this file safe. You will need to apply it in the namespaces of your other subsystems so that they can communicate with the management subsystem.

Previous topic: Installing the management subsystem
Next topic: Installing the gateway subsystem

Installing the gateway subsystem

Install the gateway subsystem by creating and applying the ingress-ca, common-issuer, gateway-certs and gateway_cr yaml files.

Before you begin

Important: When you install the gateway subsystem, you must configure the gateway subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Using the file obtained from Extracting the management ingress-ca certificates, run: `oc apply -f ingress-ca.yaml -n <gateway namespace>`
2. Create a file called `common-issuer-and-gateway-certs.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels:
    app.kubernetes.io/instance: management

  - "key encipherment"
  duration: 17520h # 2 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
```

3. Apply the above yaml file with: oc apply -f common-issuer-and-gateway-certs.yaml -n <gateway namespace>
4. Confirm that the issuers were created and are in ready state:

```
oc get issuers -n <gateway namespace>
NAME                READY
ingress-issuer      True
selfsigning-issuer  True
```

5. Confirm that the gateway secrets were created with `oc get secrets -n <gateway namespace>`:

```
oc get secrets -n <gateway namespace>
NAME                        TYPE                                  DATA   AGE
...
gateway-peering             kubernetes.io/tls                     3      2m
gateway-service             kubernetes.io/tls                     3      2m3s
...
```

About this task

Use the OpenShift CLI to edit the custom resource template for the gateway, apply the resource, verify that the pods are up and running.

Procedure

1. Create the gateway admin secret with: `oc -n <gateway namespace> create secret generic admin-secret --from-literal=password=admin`
2. If you are installing the API Gateway (v6), create a yaml file that is called `apigateway_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at

    secretName: gateway-peering
  datapowerLogLevel: 3
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  adminUser:
    secretName: admin-secret
  mtlsValidateClient: true
  # syslogConfig:
  #   enabled: false # if true, provide below details
  #   remoteHost: $DATAPOWER_SYSLOG_TCP_REMOTE_HOST # must be a string
  #   remotePort: $DATAPOWER_SYSLOG_TCP_REMOTE_PORT # must be an int
  #   secretName: $DATAPOWER_SYSLOG_TCP_TLS_SECRET # must be a string
```

3. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

`version: <version_number>`

Example version number: 10.0.8.2-ifix1

$PROFILE
Specify your gateway subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
gatewayEndpoint:
      < ... >
    hosts:
    - name: rgw.myhost.subnet.example.com
      secret: gwv6-endpoint

  gatewayManagerEndpoint:
      < ... >
    hosts:
    - name: rgwd.myhost.subnet.example.com
      secret: gwv6-manager-endpoint
```

- Complete hostname customization
  Change both the predefined prefixes and the **STACK_HOST** subdomain to match your desired hostnames.

  For example, for **gatewayEndpoint**, you can replace **rgw.$STACK_HOST** with **my.gateway.endpoint.myhost.subnet.example.com**, where **my.gateway.endpoint** replaces **rgw**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

```
gatewayEndpoint:
      < ... >
    hosts:
    - name: my.gateway.endpoint.myhost.subnet.example.com
      secret: gwv6-endpoint
```

You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
The OCP storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**.

```
storageClassName: local-storage
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

syslogConfig
To enable this feature uncomment this section, set **enabled: true**, and set the properties:

$DATAPOWER_SYSLOG_TCP_REMOTE_HOST
remoteHost: <*remote.host*>
String. The hostname of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_REMOTE_PORT
remotePort: <*remote_port_number*>
Integer. The port number of the server for **syslogConfig**.

$DATAPOWER_SYSLOG_TCP_TLS_SECRET
secretName: <*secret*>
String. The TLS secret name of the server for **syslogConfig**.

4. Optional: If applicable to your deployment, update the gateway CR file to configure **DataPowerService** APIs to customize your DataPower deployment. See Customizing a DataPower deployment.
5. Optional: If you want to enable JWT security for communications between the management and gateway, add and set the property **jwksUrl**, and set **spec.mtlsValidateClient** to false.

```
spec:
  ...
  jwksUrl: <JWKS URL>
  mtlsValidateClient: false
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
6. Optional: Update the gateway CR file to enable autoscaling of gateway pods to ensure high availability of DataPower pods. See Enabling autoscaling of gateway pods.
7. Install the gateway Custom Resource by applying the yaml file:
For a DataPower® API Gateway, run the following command:

```
oc apply -f apigateway_cr.yaml -n <namespace>
```

For a DataPower Gateway (v5 compatible), run the following command:

```
oc apply -f v5cgateway_cr.yaml -n <namespace>
```

8. To verify that the gateway subsystem is fully installed, run the following command:

```
oc get GatewayCluster -n <namespace>
```

The installation is complete when the **READY** status is **True**, and the **SUMMARY** reports that all services are online (**2/2**) for all the gateway subsystems that were installed. Example:

```
NAME   READY   SUMMARY   VERSION     RECONCILED VERSION   AGE
gwv6   True    2/2       <version>   <version-build>      7m32s
```

There is no need to wait for the **READY** status to be **True** before moving on to next Subsystem installation.
9. Verify that the gateway is ready to be registered with the Management subsystem by calling the **health** api on the **gatewayManagerEndpoint.hosts.name** defined in your yaml file: **https://gwd.$STACK_HOST/health**.

```
curl -k https://gwd.example.com/health
{"status":"ok"}
```

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Extracting the management ingress-ca certificates
Next topic: Installing the portal subsystem

Installing the portal subsystem

Install the portal subsystem by creating and applying the ingress-ca, common-issuer, and portal_cr yaml files.

Before you begin

Important: When you install the portal subsystem, you must configure the portal subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Using the file obtained from Extracting the management ingress-ca certificates, run: `oc apply -f ingress-ca.yaml -n <portal namespace>`
2. Create a file called `common-issuer.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

spec:
  ca:
    secretName: ingress-ca
```

3. Apply the above yaml file with: `oc apply -f common-issuer.yaml -n <portal namespace>`
4. Confirm that the issuers were created and are in ready state:

```
oc get issuers -n <portal namespace>
NAME                 READY
ingress-issuer       True
selfsigning-issuer   True
```

About this task

Use the OpenShift CLI to edit the custom resource template for the portal subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called `portal_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at

    storageClassName: $STORAGE_CLASS
    volumeSize: 20Gi
  certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
  adminClientSubjectDN: CN=portal-admin-client,O=cert-manager
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
```

2. Edit the yaml file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.8.2-ifix1

$PROFILE
Specify your portal subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when you specify endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can do one of the following:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **STACK_HOST** to be the desired ingress subdomain for the API Connect stack. For example, for a subdomain of **myhost.subnet.example.com**:

```
portalAdminEndpoint:
    < ... >
    hosts:
    - name: api.portal.myhost.subnet.example.com
      secret: portal-admin

  portalUIEndpoint:
```

```
    < ... >
    hosts:
    - name: portal.myhost.subnet.example.com
      secret: portal-web
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, for **portalAdminEndpoint**, you can replace **api.portal.$STACK_HOST** with **my.api.portal.myhost.subnet.example.com**, where **my.api.portal** replaces **api.portal**, and **myhost.subnet.example.com** replaces **$STACK_HOST**:

```
portalAdminEndpoint:
       < ... >
    hosts:
    - name: my.api.portal.myhost.subnet.example.com
      secret: cm-endpoint
```

  You can do this for some or all of the hostnames, depending on your customization requirements.

$STORAGE_CLASS
: The Kubernetes storage class to be used for Persistent Volume Claims. Find the available storage classes in the target cluster by running the following command: **oc get sc**. For example, for local storage:

```
databaseVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
databaseLogsVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 12Gi
webVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 200Gi
backupVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 300Gi
adminVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 20Gi
certVolumeClaimTemplate:
    storageClassName: $STORAGE_CLASS
    volumeSize: 4Gi
```

  Note:
  - The **databaseVolumeClaimTemplate** has a minimum value of 30Gi. The **webVolumeClaimTemplate** has a minimum value of 20Gi. The **backupVolumeClaimTemplate** has a minimum value of 30Gi. However, all three need to be sized according to the installation. For more information on planning your portal PV requirements, see Portal subsystem.
  - The **adminVolumeClaimTemplate** and **databaseLogsVolumeClaimTemplate** in this example have their minimum values and you do not need to change them.
  - The **certVolumeClaimTemplate** is used by the nginx pod and in 2DCDR mode it is also by the **tunnel**, **db-remote** and **www-remote** pods. It can be sized small, just like the **adminVolumeClaimTemplate**, and does not need to be increased based on the number of sites.

$LICENSE_ACCEPTANCE
: Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
: Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
: Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you want to disable mTLS for communications between the management and portal, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

   where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

   For more information about JWT security, see Enable JWT security instead of mTLS.
4. Install the portal subsystem by applying the modified CR with the following command:

```
oc apply -f portal_cr.yaml -n <namespace>
```

5. Verify that the portal subsystem is fully installed:

```
oc get PortalCluster -n <namespace>
```

   The installation is complete when **STATUS** reports **Running**, **Ready** reports that all services are online (**3/3**), and **MESSAGE** reports "Ready for API Cloud Manager service registration", for example:

```
NAME           READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                  AGE
portal         3/3     Running   <version>  <version>            Ready for API Cloud Manager service registration   2h
```

You do not need to wait for the portal installation to complete before you move on to the next subsystem installation.

6. Verify that you can access the portal web endpoint by browsing to the `portalUIEndpoint.hosts.name` as configured in your yaml file:

```
curl -k https://portal.$STACK_HOST
<!DOCTYPE html>
<html>
<head>
<title>Developer Portal is ready to create sites!</title>
<style>
    body {
        width: 35em;
        margin: 0 auto;
        font-family: Tahoma, Verdana, Arial, sans-serif;
    }
</style>
</head>
<body>Developer Portal is ready to create sites!</h1>
<p>If you see this page, the web server is successfully installed and
working. Further configuration is required.</p>
</body>
</html>
```

7. It is highly recommend that you retain the portal subsystem encryption secret in a safe location, in case you need to restore the portal subsystem during a disaster recovery scenario.
   The encryption secret is created when the portal subsystem is initially deployed. You can obtain the name of the encryption secret from the portal subsystem custom resource after the installation is complete:

   a. Obtain the name of the encryptionSecret:

   ```
   oc get ptl portal -o yaml -n <namespace> | grep encryptionSecret
   encryptionSecret: portal-enc-key
   ```

   The name of encryption secret is `portal-enc-key`.

   b. Save the secret yaml in a safe location:

   ```
   oc get secret portal-enc-key -o yaml -n <namespace> > portal-enc-key.yaml
   ```

8. Backup the portal installation. See Backing up and restoring the developer portal.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the gateway subsystem
Next topic: Installing the analytics subsystem

Installing the analytics subsystem

Install the analytics subsystem by creating and applying the ingress-ca, common-issuer, and analytics_cr yaml files.

Before you begin

Important: When you install the analytics subsystem, you must configure the analytics subsystem so that communication from the management subsystem is secured with either mTLS or JWT. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.
When installing subsystems in different namespaces you must first create the cert-manager issuers and certificates required by that subsystem in the same namespace.

1. Using the file obtained from Extracting the management ingress-ca certificates, run: `oc apply -f ingress-ca.yaml -n <analytics namespace>`
2. Create a file called `common-issuer.yaml` and paste in these contents:
   Note: If you have just done Installing the portal subsystem then you will already have this file.

```

# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels:
    app.kubernetes.io/instance: management
```

```
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: selfsigning-issuer
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
  labels:
    app.kubernetes.io/instance: management
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: ingress-issuer
spec:
  ca:
    secretName: ingress-ca
```

3. Apply the above yaml file with: `oc apply -f common-issuer.yaml -n <analytics namespace>`
4. Confirm that the issuers were created and are in ready state: `oc get issuers -n <analytics namespace>`

```
oc get issuers -n <analytics namespace>
NAME                 READY
ingress-issuer       True
selfsigning-issuer   True
```

About this task

Use the OpenShift CLI to edit the custom resource template for the analytics subsystem, apply the resource, verify that the pods are up and running.

Procedure

1. Create a file that is called `analytics_cr.yaml` and paste in these contents:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

apiVersion: analytics.apiconnect.ibm.com/v1beta1
kind: AnalyticsCluster
metadata:
  name: analytics
  labels:
    app.kubernetes.io/instance: analytics
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: analytics
annotations:
    apiconnect-operator/cp4i: "false"
spec:
  version: $APP_PRODUCT_VERSION
  license:
    accept: $LICENSE_ACCEPTANCE
    use: $LICENSE_USE
    license: '$LICENSE_ID'
  profile: $PROFILE
  microServiceSecurity: certManager
  certManagerIssuer:
    name: selfsigning-issuer
    kind: Issuer
  ingestion:
    endpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: ai.$STACK_HOST
        secretName: analytics-ai-endpoint
    clientSubjectDN: CN=analytics-ingestion-client,O=cert-manager
  storage:
    type: $STORAGE_TYPE
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
   #master: # uncomment this section if you set storage.type = dedicated.
   #  volumeClaimTemplate:
   #    storageClassName: $STORAGE_CLASS
```

2. Edit the YAML file and set the variables:

$APP_PRODUCT_VERSION
API Connect application version for the subsystems.

```
version: <version_number>
```

Example version number: 10.0.8.2-ifix1

$PROFILE
Specify your analytics subsystem profile, where **n** indicates number of replicas, **c** number of cores, and **m** is the minimum memory allocation in GB. For more information on profiles, see Deployment and component profiles.
Note: The profile that you select influences your storage type options. If you select an **n1** profile then you must select the **shared** storage type. For more information about storage types, see storage types.

$STACK_HOST
The desired ingress subdomain for the API Connect stack. Used when specifying endpoints. Domain names that are used for endpoints cannot contain the underscore "_" character. You can customize the subdomain or the complete hostname:

- Subdomain customization only
  Accept the prefixes predefined for the ingress hostnames to use and replace all instances of **$STACK_HOST** with the desired ingress subdomain for the API Connect stack. For example, if your host is **myhost.subnet.example.com**:

```
  ingestion:
    endpoint:
       < ... >
      hosts:
      - name: ai.myhost.subnet.example.com
        secret: analytics-ai-endpoint
       < .... >
```

- Complete hostname customization
  Change both the predefined prefixes and the **$STACK_HOST** subdomain to match your desired hostnames.

  For example, you can replace **$STACK_HOST** with **my.analytics.ingestion.myhost.subnet.example.com**, where **my.analytics.ingestion** replaces **ai**, and **myhost.subnet.example.com** replaces **STACK_HOST**.

```
ingestion:
    endpoint:
      < ... >
      hosts:
      - name: my.analytics.ingestion.myhost.subnet.example.com
        secret: analytics-ai-endpoint
       < ... >
```

$STORAGE_TYPE
If you set **$PROFILE** to an **n1** (one replica) profile, then set this to **shared**. If you set **$PROFILE** to an **n3** (three replica) profile then set this to **dedicated** and uncomment the **storage.master** section, for example:

```
  storage:
    type: dedicated
    shared:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
        volumeSize: $DATA_VOLUME_SIZE
    master:
      volumeClaimTemplate:
        storageClassName: $STORAGE_CLASS
```

For more information about storage types, see dedicated or shared storage.

$STORAGE_CLASS
The Kubernetes storage class to be used for persistent volume claims. For more information, see Analytics preinstallation planning. Find the available storage classes in the target cluster by running the following command: **oc get sc**. Example:

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
```

$DATA_VOLUME_SIZE
Size of storage allocated for data. To estimate the storage space you require, see Estimating storage requirements. If you are unable to estimate your storage requirement then set it to 500Gi.

```
storage:
    type: shared
    shared:
      volumeClaimTemplate:
        storageClassName: ceph-block
        volumeSize: 500Gi
```

$LICENSE_ACCEPTANCE
Set **accept** to **true**. You must accept the license to successfully deploy API Connect.

$LICENSE_USE
Set **use** to either **production** or **nonproduction** to match the license that you purchased.

$LICENSE_ID
Set **license:** to the license ID for the version of API Connect that you purchased. See API Connect licenses.

3. Optional: If you want to disable mTLS for communications between the management and analytics subsystem, and between the gateway and analytics subsystem, and enable JWT instead, then add and set the properties **mtlsValidateClient** and **jwksUrl**.

```
spec:
  ...
```

```
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

where *<JWKS URL>* is the URL of the JWKS endpoint that is hosted on the management subsystems. To find out the **jwksUrl**, describe the management CR and check the **status:** section:

```
kubectl describe mgmt -n <namespace>
...
status:
  - name: jwksUrl
    secretName: api-endpoint
    type: API
    uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

For more information about JWT security, see Enable JWT security instead of mTLS.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow.

4. Optional: If you plan to configure analytics database backups, then define the storage that is required for backups:
   Define your backup PVC by adding the **backup.volumeClaimTemplate** property in **spec.storage**. For example:

```
spec:
  storage:
    backup:
      volumeClaimTemplate:
        storageClassName: <storage class>
        volumeSize: <size>
```

   If you are not sure of the volume size that you need, then you can configure the **backup.volumeClaimTemplate** after installation.

5. Install the analytics subsystem by applying the modified CR with the following command:

```
oc apply -f analytics_cr.yaml -n <namespace>
```

6. Verify that the analytics subsystem is fully installed:

```
oc get AnalyticsCluster -n <namespace>
```

   The installation is complete when **READY** shows all pods running (**n/n**), and the **STATUS** reports **Running**. Example:

```
NAME         READY   STATUS    VERSION          RECONCILED VERSION   AGE
analytics    n/n     Running   10.0.8.0   10.0.8.0-1281    86m
```

   It is not necessary to wait for analytics installation to complete before you move on to the next subsystem installation.

7. Backup your analytics subsystem and configure scheduled analytics database backups: Backing up and restoring the analytics subsystem.

What to do next

If you are creating a new deployment of API Connect, install other subsystems as needed.

When you have completed the installation of all required API Connect subsystems, you can proceed to defining your API Connect configuration by using the API Connect Cloud Manager; refer to the Cloud Manager configuration checklist.

Previous topic: Installing the portal subsystem

Installing with the top-level CR on OpenShift

Use the single, top-level **APIConnectCluster** CR to deploy API Connect on OpenShift.

About this task

When you deploy API Connect with a top-level CR, all the API Connect subsystems are deployed in the same namespace. The CR contains a section for each subsystem; configure deployment settings in the appropriate section for each subsystem.
Note: The top-level CR installation creates and manages one instance of each subsystem. If you want multiple portal, gateway, or analytics subsystems in your API Connect deployment, then install the API Connect subsystems individually: Installing API Connect in a single namespace on OpenShift. For more information about API Connect installation options on OpenShift, see OpenShift: Deciding to use individual CRs, a top-level CR, or Cloud Pak for Integration.
If you want to install multiple API Connect instances, for example dev, uat, and prod, the recommended configuration is to have single API Connect and Datapower operators installed globally in the **openshift-operators** namespace and each API Connect instance installed in its own namespace using a top-level CR.

Attention:

- If you want to configure FIPS support for API Connect, you must enable FIPS on the cluster as part of the initial OpenShift deployment. You cannot modify an existing cluster to enable FIPS support. For more information, see Configuring FIPS support on OpenShift.
- Linking services from one topCR deployment to another is not recommended. If you attempt to link services from one topCR deployment to another, you will likely encounter errors with certificates along with limitations on the service names. In such a scenario, you should deploy the remote analytics service using an individual AnalyticsCluster CR. For more information, see Installing API Connect subsystems in different namespaces or environments on OpenShift.

- **Installing operators**
  Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect on Red Hat OpenShift.
- **Installing API Connect**
  Use the top-level **APIConnectCluster** CR to install all the API Connect subsystems into a shared namespace on OpenShift while connected to the internet.

Installing operators

Install operators for API Connect, DataPower, and IBM Cloud Pak foundational services so that you can deploy API Connect on Red Hat OpenShift.

Before you begin

The API Connect operator and operand must be at compatible release and fix pack levels. Table 1 lists the current version of the operator and operand for API Connect.

Table 1. API Connect operator and operand versions

API Connect (operand)	Operator channel version	Highest operator version
10.0.8.2-ifix1	v5.4-sc2	5.4.1

If you want to run API Connect operator and subsystems at different versions, the following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
5.4.1	• 10.0.8.2-ifix1 • 10.0.8.1 • 10.0.8.0
5.3.0	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

Procedure

1. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step 3.
   The **ibm-pak** plug-in enables you to access hosted product images, and to run **oc ibm-pak** commands against the cluster. To confirm that **ibm-pak** is installed, run the following command and verify that the response lists the command usage:

   ```
   oc ibm-pak --help
   ```

2. Obtain an entitlement key for the Entitled Registry:
   Air-gapped: If you are in an air-gapped environment, then skip this step and instead follow the steps in Air-gapped installation, and then continue from step #inst_ocp_cp4i_ops__d290e254.
   a. Log in to the IBM Container Library.
   b. In the Container software library, select Get entitlement key.
   c. After the Access your container software heading, click Copy key.
   d. Copy the key to a safe location.
3. Create the namespace where API Connect will be installed, either by selecting Home > Projects > Create Project in the UI, or with the following command:

   ```
   oc create ns <APIC-namespace>
   ```

   The namespace where you install API Connect must meet the following requirements:
   - Red Hat OpenShift: Only one top-level CR (**APIConnectCluster**) can be deployed in each namespace.
   - Cloud Pak for Integration: Only one API Connect capability can be deployed in each namespace.
   - Red Hat OpenShift restricts the use of default namespaces for installing non-cluster services. The following namespaces cannot be used to install API Connect:
     - **default**
     - **kube-system**
     - **kube-public**
     - **openshift-node**
     - **openshift-infra**
     - **openshift**
4. If you are installing the operator into a single namespace, create an OperatorGroup object specifying that namespace.
   Attention: If you are installing the operator into all namespaces, skip this step because the **openshift-operators** namespace already has an appropriate Operator group in place.
   a. Create the apiconnect-operator-group.yaml file with an OperatorGroup object that identifies the namespace in which RBAC permissions for the IBM API Connect Operator will be generated, and where the CSV will be available:

      ```
      apiVersion: operators.coreos.com/v1
      kind: OperatorGroup
      metadata:
        name: <operator-group-name>
        namespace: <APIC-namespace>
      spec:
        targetNamespaces:
        - <APIC-namespace>
      ```

   b. Apply the OperatorGroup object with the following command:

      ```
      oc apply -f apiconnect-operator-group.yaml
      ```

5. If you are installing the operator in all namespaces, then create the common services namespace:

   ```
   oc create ns ibm-common-services
   ```

6. Create a pull secret in the namespaces where you want to install API Connect.
   Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   a. Open the Red Hat OpenShift web console, click Workloads > Secrets.
   b. Ensure that the Project is set to the namespace where you intend to install API Connect.
   c. Click Create and select Image pull secret.

d. Set the following parameters for the secret:
- Set Secret name to **ibm-entitlement-key**.
- Set Authentication type to **Image registry credentials**.
- Set Registry server address to **cp.icr.io**.
- Set Username to **cp**.
- Set Password to the entitlement key generated in Step 2.
- Click Create to create the secret.

Note: If your Red Hat OpenShift platform is Red Hat OpenShift on IBM Cloud (ROKS), you might need to reload your worker nodes after the image pull secret is created. You can reload the worker nodes either from the Red Hat OpenShift web console or from the command line with the following command: **ibmcloud oc worker reload**
For information on using the **reload** command, see the Red Hat OpenShift on IBM Cloud documentation.

7. Add the API Connect catalog sources to your cluster.
Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
Adding catalog sources to your Red Hat OpenShift cluster adds the IBM operators to the list of operators you can install. For most connected and air-gapped clusters, applying individual catalog sources is the most effective way to fully control software versioning on the cluster.

   a. Generate the catalog source files:
      i. Log into your cluster using the **oc login** command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use:

      ```
      export CASE_NAME=ibm-apiconnect
      export CASE_VERSION=5.4.1
      export ARCH=amd64
      ```

      For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

      iii. Download the files for the operators required by API Connect:

      ```
      oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
      ```

      iv. Generate the catalog sources for API Connect:

      ```
      oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
      ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

      ```
      cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

   b. Apply the catalog sources:
      i. Apply the catalog sources:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      ii. Confirm that the catalog sources have been created in the **openshift-marketplace** namespace:

      ```
      oc get catalogsource -n openshift-marketplace
      ```

8. Add the IBM Cloud Pak foundational services (common services) catalog sources to your cluster.
Air-gapped: If you are in an air-gapped environment, then skip this step as it is covered in Air-gapped installation.
   a. Generate the catalog source files:
      i. Log into your cluster using the **oc login** command and your user credentials:

      ```
      oc login <openshift_url> -u <username> -p <password> -n <APIC-namespace>
      ```

      ii. Export the variables for the command line to use; substituting the appropriate CASE version:

      ```
      export CASE_NAME=ibm-cp-common-services
      export CASE_VERSION=<case version>
      export ARCH=amd64
      ```

      Set *<case version>* to the value specified for *Foundational services CASE version* in Operator, CASE, and platform requirements, for your deployment type.

      iii. Download the files for the operators required by IBM Cloud Pak foundational services (common services):

      ```
      oc ibm-pak get ${CASE_NAME} --version ${CASE_VERSION}
      ```

      iv. Generate the catalog sources:

      ```
      oc ibm-pak generate mirror-manifests ${CASE_NAME} icr.io --version ${CASE_VERSION}
      ```

      v. Optionally get the catalog sources and save them in another directory in case you need to replicate this installation in the future:
      Get the catalog sources:

      ```
      cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      This command might not return anything if there are no architecture-specific catalog sources.

   b. Apply the catalog sources:
      i. Apply the catalog sources:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
      ```

      ii. Confirm that the catalog sources have been created in the **openshift-marketplace** namespace:

```
oc get catalogsource -n openshift-marketplace
```

9. Create the **apiconnect** subscription.
   a. Create the **apiconnect** subscription with the appropriate channel by creating a file called **apic-sub.yaml** and pasting in the following contents, updating the namespace as required:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-apiconnect
  namespace: <namespace>
spec:
  channel: v5.4-sc2
  name: ibm-apiconnect
  source: ibm-apiconnect-catalog
  sourceNamespace: openshift-marketplace
```

   Where ***<namespace>*** is one of the following values:
   - **openshift-operators** if you are installing the operator in all namespaces
   - The namespace created in step 3 if you are installing the operator in a single namespace

   b. Apply the subscription with the following command:

```
oc apply -f apic-sub.yaml
```

   c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
   If any operators such as **ibm-apiconnect** or **IBM DataPower Gateway** show the status of "Upgrade available", approve the upgrade by completing the following steps:

      i. Click Upgrade available.
      ii. Click Preview InstallPlan.
      iii. Click Approve.
      iv. Wait for the **IBM API Connect** and **IBM DataPower Gateway** operators to install.

   The **IBM DataPower Gateway** operator is a prerequisite to API Connect and must not be removed.

10. Install cert manager by completing the following steps:
    a. Log in to the OpenShift Container Platform web console.

    b. Navigate to Operators > OperatorHub.

    c. In the filter box, type: **cert-manager Operator for Red Hat OpenShift**.

    d. Select cert-manager Operator for Red Hat OpenShift and click Install.

    e. On the Install Operator page, complete the following steps:
       i. Update the Update channel if needed. The channel defaults to **stable-v1**, which installs the latest stable release of the cert-manager Operator for Red Hat OpenShift.

       ii. Select the Installed Namespace for the operator.
       The default operator namespace is **cert-manager-operator**; if that namespace doesn't exist, it is created for you.

       iii. Select an Update approval strategy:
          - Automatic: allow Operator Lifecycle Manager (OLM) to automatically update the operator when a new version is available.
          - Manual: require a user with the appropriate credentials to approve all operator updates.

       iv. Click Install.

    f. Verify the cert-manager installation by completing the following steps:
       i. Click to Operators > Installed Operators.

       ii. Verify that **cert-manager Operator for Red Hat OpenShift** is listed with a Status of **Succeeded** in the **cert-manager-operator** namespace.

       iii. Verify that cert-manager pods are up and running by running the following command:

```
oc get pods -n cert-manager
```

       For a successful installation, the response looks like the following example:

```
NAME                                       READY   STATUS    RESTARTS   AGE
cert-manager-bd7fbb9fc-wvbbt               1/1     Running   0          3m39s
cert-manager-cainjector-56cc5f9868-7g9z7   1/1     Running   0          4m5s
cert-manager-webhook-d4f79d7f7-9dg9w       1/1     Running   0          4m9s
```

11. Create the **ibm-common-services-operator** subscription, if it does not already exist.
    a. Create a file called common-services-sub.yaml and paste in the following contents:

```
apiVersion: operators.coreos.com/v1alpha1
kind: Subscription
metadata:
  name: ibm-common-service-operator
  namespace: <namespace>
spec:
  channel: v4.6
  name: ibm-common-service-operator
  source: opencloud-operators
  sourceNamespace: openshift-marketplace
```

    Where: ***<namespace>*** is one of the following values:

    - **openshift-operators** if you are installing the operator in all namespaces
    - The namespace created in step 3 if you are installing the operator in a single namespace

b. Apply the subscription with the following command:

```
oc apply -f common-services-sub.yaml
```

c. Select Operators > Installed Operators, and ensure that Project: All Projects is selected.
If any operators such as **ibm-apiconnect**, **IBM Cloud Pak foundational services**, or **Operand Deployment Lifecycle Manager** show the status of "Upgrade available", approve the upgrade by completing the following steps:

i. Click Upgrade available.
ii. Click Preview InstallPlan.
iii. Click Approve.
iv. Check the **ibm-common-services** namespace and ensure that all operators with a status of "Upgrade available" are approved.
v. Wait for the **IBM Cloud Pak foundational services** and **Operand Deployment Lifecycle Manager** operators to install.

Installing API Connect

Use the top-level **APIConnectCluster** CR to install all the API Connect subsystems into a shared namespace on OpenShift while connected to the internet.

Before you begin

Review installation considerations and complete and prerequisite tasks as explained in:

1. Preparing for installation
2. Installing operators

About this task

Important: When you install API Connect, you must configure secure communication between subsystems. Use mTLS or JWT for management to portal and analytics subsystems. Use JWT for management to gateway communication. For more information on inter-subsystem communication, see Network requirements for inter-subsystem communication.

Procedure

1. Install the subsystems using the OpenShift web console.
API Connect uses a single top-level **APIConnectCluster** CR to quickly deploy all of the subsystems. With the **APIConnectCluster** CR, you provide values for a few properties, and then the installation logic chooses sensible defaults for the other properties during subsystem deployment.

a. Click Operators->Installed Operators.
b. Select the IBM API Connect operator.
c. Click Create Instance on the API Connect cluster tile to install the top-level Custom Resource.
Selecting API Connect cluster installs all the API Connect subsystems with the default configuration. The API Connect subsystems are Management, Developer Portal, Gateway, and Analytics.

d. Provide values for the fields shown in Table 1.

Table 1. Properties for the API Connect top-level CR

Input	Value
Name	The name to be used when deploying the **APIConnectCluster** CR.
License acceptance	Required. Click to accept the license. You must accept the license to install API Connect.
License use	Required. Select production or nonproduction to match the type of license that you purchased.
License metric	Optional. Enter the unit of measurement that is used for your program license: • PROCESSOR_VALUE_UNIT - Default value. If you leave the field blank, this value is used. • MONTHLY_API_CALL - Applies only to the IBM API Connect Hybrid Entitlement program.
License ID	Required. Select the license ID for the API Connect program that you purchased. To view all license IDs, see API Connect licenses.
Deployment profile	The deployment profile defines the number of worker nodes, CPU, and memory that is available for API Connect. The available profiles are listed in API Connect deployment profiles for OpenShift and Cloud Pak for Integration.
Product version	Optional. The API Connect application version. Defaults to the latest version available.
Default storage class name	The name of the Storage class to be used. You can set a default to appear here with the command: `oc patch storageclass <storage class name> -p '{"metadata": {"annotations": {"storageclass.kubernetes.io/is-default-class":"true"}}}'`
Database Backup settings	
Backup Certs	The name of the Kubernetes secret containing your S3 access key and secret or your or SFTP username and password or SSH key. Default: (Generated Value) See Configuring management database backups.
Backup S3 URI style	Indicates whether URIs to your S3 backup specify a host or a path value. Set to either **host** or **path**.
Credentials	The name of the Kubernetes secret containing your S3 access key and secret or your or SFTP username and password or SSH key. Default: (Generated Value) See Configuring management database backups.

Input	Value
Server hostname	Hostname of your remote SFTP backup server or object-store endpoint. If specifying an S3 object-store, use the format **<S3endpoint>/<S3region>**. For example: **s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard** Default: none See Configuring management database backups.
Path	The path to the location of for your backups on your remote server. If you are using a remote SFTP server, then this is a directory path. If you are using an object-store, then this is the name of your S3 bucket. For example, **bucket-name/folder**. The use of subdirectories in the bucket name is not supported. Ensure that **bucket-name/folder** is empty. Default: none See Configuring management database backups.
Server port	Not used for S3 object-store backups.
RepoRetentionFull	The number of days to retain backups for. For example, if **RepoRetentionFull** is set to 30, then any backups older than 30 days are deleted.
Schedule	Cron like schedule for performing automatic backups. The format for the schedule is: • * * * * * * • - - - - - - • | | | | | | • | | | | | +----- day of week (0 - 6) (Sunday=0) • | | | | +------- month (1 - 12) • | | | +--------- day of month (1 - 31) • | | +----------- hour (0 - 23) • | +------------- min (0 - 59) • +--------------- sec (0 - 59) The backup schedule defaults to **0 0 * * * ***. This means a backup is run every day at midnight and minute zero UTC. When you configure a host, if you do not specify a value for **schedule**, the default backup schedule is automatically set. Note that the default backup schedule is not set, and scheduled backups not enabled, until host configuration is completed. See Configuring management database backups.

e. If you want to configure additional settings, click Advanced and see API Connect configuration settings for information on the advanced settings.
f. Optional: If Cloud Pak for Integration is installed, and you want your API Connect installation to be integrated with it, then click the **YAML** tab and set **metadata.annotations.apiconnect-operator/cp4i** to **true**.
This annotation enables integration with Cloud Pak for Integration.

2. Optional: If you are installing API Connect as a Cloud Pak for Integration component and you want to deploy with Cloud Pak endpoints, complete the following steps. This step is not applicable if you already disabled API Connect integration with Cloud Pak for Integration by setting **metadata.annotations.apiconnect-operator/cp4i** to false.
Beginning with version 10.0.7.0, API Connect no longer uses the Cloud Pak cpd routes for endpoints when deployed as a component of Cloud Pak for Integration. Instead, the API Management component uses the typical default API Connect routes (or the custom endpoints configured in the CR).

   a. Click the YAML tab to manually edit the CR.
   b. Insert the **deprecatedCloudPakRoute** object into the **spec.management** section as shown in the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-minimum
  name: <name_of_your_instance>
  namespace: <APIC-namespace>
spec:
  license:
    accept: true
    license: L-MMBZ-295QZQ
    metric: PROCESSOR_VALUE_UNIT
    use: nonproduction
  profile: n1xc17.m48
  version: 10.0.8.0
  storageClassName: <default-storage-class>
  management:
    deprecatedCloudPakRoute:
      enabled: true
      cloudPakEndpoint:
        hosts:
        - name: cpd-apic.apps.admin-<domain>.com
```

   c. Optional: If you want to add a custom certificate for the Cloud Pak route, complete the following steps:
      i. Create a Cloud Pak certificate that was signed by a Cloud Pak CA as in the following example:

```
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
 name: custom-cpd-ca
 namespace: apic
spec:
 selfSigned: {}
```

```
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: custom-cpd
  namespace: apic
spec:
  commonName: small-mgmt-cpd
  dnsNames:
  - cpd-apic.apps.admin-apickeycloak.cp.fyre.ibm.com
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: custom-cpd-ca
  privateKey:
    algorithm: RSA
    rotationPolicy: Always
    size: 2048
  renewBefore: 720h0m0s
  secretName: custom-cpd
  usages:
  - key encipherment
  - digital signature
  - server auth
```

ii. In the CR, provide the secret name within the `cloudPakEndpoint` property of the new `deprecatedCloudPakRoute` object; for example:

```
spec:
  deprecatedCloudPakRoute:
    enabled: true
    cloudPakEndpoint:
      hosts:
      - name: cpd-apic.apps.admin-<domain>.com
        secretName: custom-cpd
```

3. Click Create to install API Connect.
4. To verify that your API Connect cluster is successfully installed, run `oc get apic -n <APIC-namespace>`.
5. Verify that you can log in to the API Connect Cloud Manager UI:
   a. To determine the location for logging in, view all the endpoints:

   ```
   oc get routes -n <APIC-namespace>
   ```

   b. Locate the `mgmt-admin-apic` endpoint, and access the Cloud Manager UI.
   c. Login as `admin`.
   When you install with the top-level CR, the password is auto-generated. To get the password, run the following commands:

   ```
   oc get secret -n <APIC-namespace> | grep mgmt-admin-pass

   oc get secret -n <APIC-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d &&
   echo ""
   ```

6. Optional: Complete the following tasks:
   - Increase the timeout settings for management endpoints, particularly for large deployments. See Configuring timeouts for management endpoints.
   - Download the API Connect toolkit from the Cloud Manager UI or API Manager UI after installation is completed. See Installing the toolkit.
   - Install a test environment. See Testing an API with the Local Test Environment.

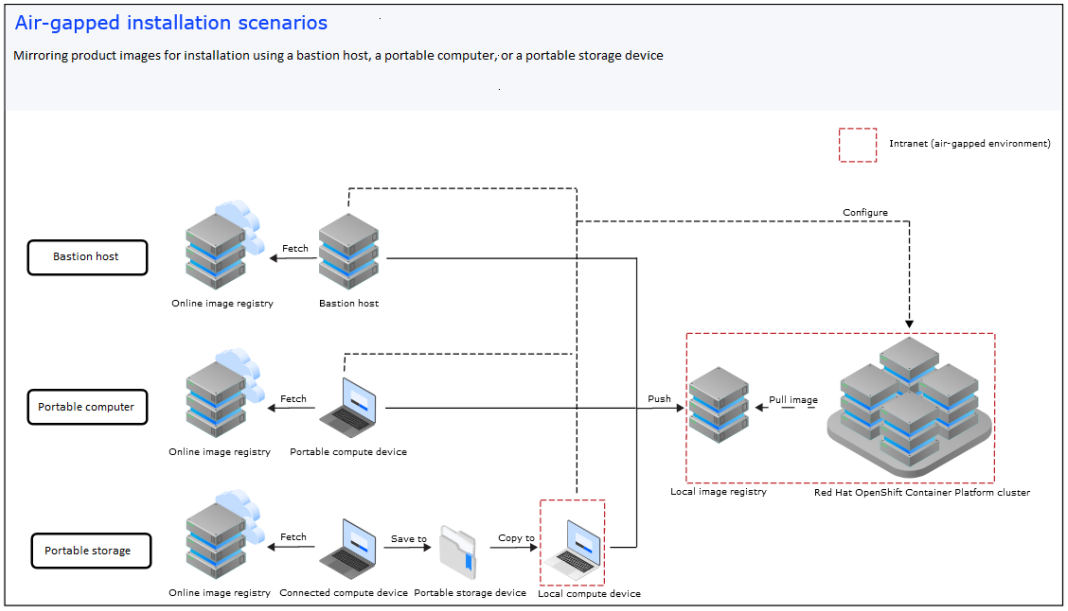
   Note: You can also install the Toolkit and Local Test Environment from IBM Fix Central. For a link to the latest files on Fix Central, see What's new in the latest release.

What to do next

Configure backups for all your API Connect subsystems: Backing up, restoring, and disaster recovery.

Air-gapped installation

In a disconnected environment using Red Hat OpenShift Container Platform (OCP), install API Connect by mirroring product images to a bastion host or a portable device and then completing the installation.



Before you begin

- An air-gapped installation is not possible in the following environments:
  - Red Hat OpenShift Service on AWS (ROSA)
  - Red Hat OpenShift Service Kubernetes Service on IBM Cloud (ROKS)

About this task

If your cluster is not connected to the internet (it is network-restricted, or air-gapped), you can install API Connect in your cluster by using either a bastion host, a portable computer, or a portable storage device.

The following diagram illustrates how you can mirror product images for an air-gapped installation with a bastion host, a portable computer, or a portable storage device.

All of the scenarios use Container Application Software for Enterprises (CASE) files to mirror content from a source (on the internet) to an intermediary target (a bastion host, a portable computer, or a portable storage device) before pushing them to a local server or device.

Then, you can transfer the files to the local air-gapped network and run the installation.

- **Installing with a bastion host**
  You can use a bastion host to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.
- **Installing with a portable computer or storage device**
  You can use a portable device, such as a portal computer or a USB storage device, to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

Installing with a bastion host

You can use a bastion host to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

Before you begin

This task must be performed by a Red Hat OpenShift administrator.

About this task

If your cluster is not connected to the internet, you can mirror product images to a registry in your network-restricted environment by using a bastion host. A bastion host has access to both the public internet and the network-restricted environment where the target clusters reside. You can fetch product images from the internet and push them to a local registry; then you can pull the images from the local registry to the target cluster for installation.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in IBM API Connect Version 10 software product compatibility requirements.
      - Configure storage on the cluster and make sure that it is available.
   b. Prepare the bastion host:
      You must be able to connect your bastion host to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry) at the same time. Your host must be on a Linux x86_64 or Mac platform with any operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

      i. Ensure that the sites and ports listed in Table 1 can be reached from the bastion host:

      Table 1. Sites that must be reached from the bastion host

Site	Description
`icr.io:443`	IBM entitled registry
`quay.io:443`	Local API Connect image repository
`github.com`	CASE files and tools
`redhat.com`	Red Hat OpenShift Container Platform (OCP) upgrades

      ii. On the bastion host, install either Docker or Podman (not both).

Docker and Podman are used for managing containers; you only need to install one of these applications.

- To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

```
yum check-update
yum install docker
```

- To install Podman, see the Podman installation instructions.
  For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

```
yum install podman
```

iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

```
oc ibm-pak --help
```

c. Set up a local image registry and credentials.
The local Docker registry stores the mirrored images in your network-restricted environment.

i. Install a registry, or get access to an existing registry.
You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

The registry product that you use must meet the following requirements:
- Supports multi-architecture images through Docker Manifest V2, Schema 2
  For details, see Docker Manifest V2, Schema 2.
- Is accessible from the Red Hat OpenShift Container Platform cluster nodes
- Allows path separators in the image name

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

ii. Configure the registry to meet the following requirements:
- Supports auto-repository creation
- Has sufficient storage to hold all of the software that is to be transferred
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials)
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials)

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries during runtime, use an account that can read from the target local registry.

2. Mirror the cert-manager operator for Red Hat OpenShift.
Mirror the operator as explained in the Red Hat instructions: Mirroring images for a disconnected installation using the oc-mirror plugin .

When you modify the `ImageSetConfiguration`, include `openshift-cert-manager-operator` at channel `stable-v1` as one of the packages, as shown in the following example:

```
    packages:
    - name: openshift-cert-manager-operator
      channels:
      - name: stable-v1
```

3. Set environment variables and download CASE files.
Because you will use values from two different CASE files, you must create environment variables for both; notice that the variables for the foundational services (common services) CASE file are prefixed with "CS_" to differentiate them.

a. Create the following environment variables with the installer image name and the image inventory on your host:
- API Connect:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.4.1
export ARCH=amd64
```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

- Foundational services:

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

- EDB:

```
export EDB_CASE_NAME=ibm-cloud-native-postgresql
export EDB_CASE_VERSION=5.2.0
```

b. Connect your host to the internet (it does not need to be connected to the network-restricted environment at this time).
c. Download the CASE files to your portable device:
- API Connect:

```
oc ibm-pak get $CASE_NAME --version $CASE_VERSION
```

- Foundational services:

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

- EDB:

```
oc ibm-pak get $EDB_CASE_NAME --version $EDB_CASE_VERSION
```

4. Mirror the images.
   The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before installing API Connect.

   a. Generate mirror manifests.
      i. Define the environment variable $TARGET_REGISTRY by running the following command:

      ```
      export TARGET_REGISTRY=<target-registry>
      ```

      Replace ***<target-registry>*** with the IP address (or host name) and port of the local registry; for example: **172.16.0.10:5000**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **172.16.0.10:5000/registry_ns**.
      ii. Generate mirror manifests by running the following commands:
      - API Connect:

      ```
      oc ibm-pak generate mirror-manifests $CASE_NAME --version $CASE_VERSION $TARGET_REGISTRY
      ```

      - Foundational services:

      ```
      oc ibm-pak generate mirror-manifests $CS_CASE_NAME --version $CS_CASE_VERSION $TARGET_REGISTRY
      ```

      - EDB:

      ```
      oc ibm-pak generate mirror-manifests $EDB_CASE_NAME --version $EDB_CASE_VERSION $TARGET_REGISTRY
      ```

      If you need to filter for a specific image group, add the parameter **--filter** ***<image_group>*** to the command.

   The **generate** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION, ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION, and ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION:
   - catalog-sources.yaml
   - catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
   - image-content-source-policy.yaml
   - images-mapping.txt

   The files are used when mirroring the images to the **TARGET_REGISTRY**.

   b. Obtain an entitlement key for the entitled registry where the images are hosted:
      i. Log in to the IBM Container Library.
      ii. In the Container software library, select Get entitlement key.
      iii. In the "Access your container software" section, click Copy key.
      iv. Copy the key to a safe location; you will use it to log in to **cp.icr.io** in the next step.

   c. Authenticate with the entitled registry where the images are hosted.
   The image pull secret allows you to authenticate with the entitled registry and access product images.

      i. Run the following command to export the path to the file that will store the authentication credentials that are generated on a Podman or Docker login:

      ```
      export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
      ```

      The authentication file is typically located at $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

      ii. Log in to the **cp.icr.io** registry with Podman or Docker; for example:

      ```
      podman login cp.icr.io
      ```

      Use **cp** as the username and your entitlement key as the password.

   d. Authenticate with the local registry.
   Log in to the local registry using an account that can write images to that registry; for example:

   ```
   podman login $TARGET_REGISTRY
   ```

   If the registry is insecure, add the following flag to the command: **--tls-verify=false**.

   e. Update the CASE manifest to correctly reference the DataPower Operator image.
   Files for the DataPower Operator are now hosted on **icr.io**; however, the CASE manifest still refers to **docker.io** as the image host. To work around this issue, visit Airgap install failure due to 'unable to retrieve source image docker.io' in the DataPower documentation and update the manifest as instructed. After the manifest is updated, continue to the next step in this procedure.

   f. Mirror the product images.
      i. Connect the bastion host to both the internet and the restricted-network environment that contains the local registry.
      ii. Run the following commands to copy the images to the local registry:
      - API Connect:

      ```
      oc image mirror \
        -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping.txt \
        -a $REGISTRY_AUTH_FILE \
        --filter-by-os '.*' \
        --skip-multiple-scopes \
        --max-per-registry=1
      ```

      - Foundational services:

      ```
      oc image mirror \
        -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping.txt \
        -a $REGISTRY_AUTH_FILE \
      ```

```
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

- EDB:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1
```

Note: If the local registry is not secured by TLS, or the certificate presented by the local registry is not trusted by your device, add the `--insecure` option to the command.
There might be a slight delay before you see a response to the command.

g. Configure the target cluster.
Now that images have been mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

i. Log in to your Red Hat OpenShift Container Platform cluster:

```
oc login <openshift_url> -u <username> -p <password> -n <namespace>
```

ii. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

```
oc edit image.config.openshift.io/cluster -o yaml
```

and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

```
spec:
  registrySources:
    insecureRegistries:
    - insecure0.svc:5001
    - <TARGET_REGISTRY>
```

If the `insecureRegistries` field does not exist, you can add it.

iii. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry:

- API Connect:

```
oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml
```

- Foundational services:

```
oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
```

- EDB:

```
oc apply -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/image-content-source-policy.yaml
```

iv. Verify that the ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

v. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

Wait for all nodes to be updated before proceeding to the next step.

5. Apply the catalog sources.
Now that you have mirrored images to the target cluster, apply the catalog sources for API Connect and Foundational services. There is no need to apply the catalog source for EDB because the API Connect operator will apply that catalog source in its own namespace when the API Connect operand is created.

In the following steps, replace `<Architecture>` with either `amd64` or `s390x` as appropriate for your environment.

a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.4.1
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.3
export CS_ARCH=amd64
```

b. Generate the catalog sources and save them in another directory in case you need to replicate this installation in the future.

i. Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml
```

```
cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Get any architecture-specific catalog sources that you need to back up as well:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.

i. Apply the universal catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Apply any architecture-specific catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

iii. Confirm that the catalog sources were created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

What to do next

Install API Connect following the steps for your deployment type: Deploying on OpenShift and Cloud Pak for Integration.

Installing with a portable computer or storage device

You can use a portable device, such as a portal computer or a USB storage device, to perform an air-gapped installation of API Connect on Red Hat OpenShift Container Platform (OCP) when your cluster has no internet connectivity.

Before you begin

This task must be performed by a Red Hat OpenShift administrator.

About this task

If your cluster is not connected to the internet, you can mirror product images to a registry in your network-restricted environment by using a portable device. Download images from the public registries on the internet to the portable device; then bring that portable device into the network-restricted environment (or transfer the files to a different device within the network-restricted environment) and mirror the images to the local registry. You can pull the images from the local registry to the target cluster for installation.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For more information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in Operator, CASE, and platform requirements.
      - Configure storage on the cluster and make sure that it is available.

   b. Prepare the portable device:
      You must be able to connect your portable device to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry). The portable device must be on a Linux x86_64 or Mac platform with an operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

      i. Check that the portable device has sufficient storage to hold all the software that is to be transferred to the local registry.
      ii. On the portable device, install either Docker or Podman (not both).
      Docker and Podman are used for managing containers; you can install either of these applications.

         - To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

           ```
           yum check-update
           yum install docker
           ```

         - To install Podman, see the Podman installation instructions.
           For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

           ```
           yum install podman
           ```

      iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
      The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

      iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
      The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

      ```
      oc ibm-pak --help
      ```

   c. Set up a local image registry and credentials.
      The local Docker registry stores the mirrored images in your network-restricted environment.

      i. Install a registry, or get access to an existing registry.
      You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

      The registry product that you use must meet the following requirements:
         - Supports multi-architecture images through Docker Manifest V2, Schema 2.
           For more information, see Docker Manifest V2, Schema 2.

- Is accessible from the Red Hat OpenShift Container Platform cluster nodes.
- Allows path separators in the image name.

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

ii. Configure the registry to meet the following requirements:

- Supports auto-repository creation.
- Has sufficient storage to hold all the software that is to be transferred.
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials).
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials).

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries at run time, use an account that can read from the target local registry.

2. Mirror the cert-manager operator for Red Hat OpenShift.
Mirror the operator as explained in the Red Hat instructions: Mirroring images for a disconnected installation using the oc-mirror plugin .

When you modify the **`ImageSetConfiguration`**, include **`openshift-cert-manager-operator`** at channel **`stable-v1`** as one of the packages, as shown in the following example:

```
packages:
- name: openshift-cert-manager-operator
  channels:
  - name: stable-v1
```

3. Set environment variables and download CASE files.
Create environment variables to use while mirroring images, connect to the internet, and download the CASE files needed for installing API Connect.

a. Create the following environment variables with the installer image name and the image inventory on your portable device:

- API Connect:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.4.1
export ARCH=amd64
```

For information on API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

- Foundational services:

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

For information on IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

- EDB:

```
export EDB_CASE_NAME=ibm-cloud-native-postgresql
export EDB_CASE_VERSION=5.2.0
```

b. Connect your portable device to the internet (it does not need to be connected to the network-restricted environment at this time).
c. Download the CASE files to your portable device:

- API Connect:

```
oc ibm-pak get $CASE_NAME --version $CASE_VERSION
```

- Foundational services:

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

- EDB:

```
oc ibm-pak get $EDB_CASE_NAME --version $EDB_CASE_VERSION
```

4. Mirror the images.
The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before installing API Connect.

a. Generate mirror manifests.

i. Define the environment variable $TARGET_REGISTRY by running the following command:

```
export TARGET_REGISTRY=<target-registry>
```

Replace ***`<target-registry>`*** with the IP address (or host name) and port of the local registry; for example: **`172.16.0.10:5000`**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **`172.16.0.10:5000/registry_ns`**.

ii. Generate mirror manifests by running the following commands:

- API Connect:

```
oc ibm-pak generate mirror-manifests $CASE_NAME file://integration --version $CASE_VERSION --final-registry
$TARGET_REGISTRY
```

- Foundational services:

```
oc ibm-pak generate mirror-manifests $CS_CASE_NAME file://integration --version $CS_CASE_VERSION --final-
registry $TARGET_REGISTRY
```

- EDB:

```
oc ibm-pak generate mirror-manifests $EDB_CASE_NAME file://integration --version $EDB_CASE_VERSION --final-
registry $TARGET_REGISTRY
```

If you need to filter for a specific image group, add the parameter **`--filter <image_group>`** to the command.

The **`generate`** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION, ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION, and ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION:

- catalog-sources.yaml
- catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
- image-content-source-policy.yaml
- images-mapping-to-filesystem.txt
- images-mapping-from-filesystem.txt

The files are used when mirroring the images to the **`TARGET_REGISTRY`**.

b. Obtain an entitlement key for the entitled registry where the images are hosted:
   i. Log in to the IBM Container Library.
   ii. In the Container software library, select Get entitlement key.
   iii. In the "Access your container software" section, click Copy key.
   iv. Copy the key to a safe location; you will use it to log in to **`cp.icr.io`** in the next step.

c. Authenticate with the entitled registry where the images are hosted.
The image pull secret allows you to authenticate with the entitled registry and access product images.

   i. Run the following command to export the path to the file that will store the authentication credentials that are generated on a Podman or Docker login:

   ```
   export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
   ```

   The authentication file is typically located at $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

   ii. Log in to the **`cp.icr.io`** registry with Podman or Docker; for example:

   ```
   podman login cp.icr.io
   ```

   Use **`cp`** as the username and your entitlement key as the password.

d. Update the API Connect CASE manifest to correctly reference the DataPower Operator image.
Files for the DataPower Operator are now hosted on **`icr.io`**; however, the CASE manifest still refers to **`docker.io`** as the image host. To work around this issue, visit Airgap install failure due to 'unable to retrieve source image docker.io' in the DataPower documentation and update the manifest as instructed.
The manifest for API Connect (which uses the DataPower Operator) is stored in ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION.

After the manifest is updated, continue to the next step in this procedure.

e. Mirror the images from the internet to the portable device.
   i. Define the environment variable $IMAGE_PATH by running the following command:

   ```
   export IMAGE_PATH=<image-path>
   ```

   where **`<image-path>`** indicates where the files will be stored on the portable device's file system.
   ii. Mirror the images to the portable device:
   - API Connect:

     ```
     oc image mirror \
       -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-to-filesystem.txt \
       --filter-by-os '.*' \
       -a $REGISTRY_AUTH_FILE \
       --skip-multiple-scopes \
       --max-per-registry=1 \
       --dir "$IMAGE_PATH"
     ```

   - Foundational services:

     ```
     oc image mirror \
       -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-to-filesystem.txt \
       --filter-by-os '.*' \
       -a $REGISTRY_AUTH_FILE \
       --skip-multiple-scopes \
       --max-per-registry=1 \
       --dir "$IMAGE_PATH"
     ```

   - EDB:

     ```
     oc image mirror \
       -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping-to-filesystem.txt \
       --filter-by-os '.*' \
       -a $REGISTRY_AUTH_FILE \
       --skip-multiple-scopes \
       --max-per-registry=1 \
       --dir "$IMAGE_PATH"
     ```

   There might be a slight delay before you see a response to the command.

f. Move the portable device to the restricted-network environment.
The procedure depends on the type of device that you are using:
If you are using a portable computer, disconnect the device from the internet and connect it to the restricted-network environment. The same environment variables can be used.

If you are using portable storage, complete the following steps:
   i. Transfer the following files to a device in the restricted-network environment:
   - The **`~/.ibm-pak`** directory.
   - The contents of the **`<image-path>`** that you specified in the previous step.

   ii. Create the same environment variables as on the original device; for example:
   - API Connect:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.4.1
export ARCH=amd64
```

- Foundational services:

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=1.15.10
export CS_ARCH=amd64
```

- EDB:

```
export EDB_CASE_NAME=ibm-cp-common-services
export EDB_CASE_VERSION=1.15.10
export EDB_ARCH=amd64
```

- Registry:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

- Image path:

```
export IMAGE_PATH=<image-path>
```

g. Authenticate with the local registry.
Log in to the local registry using an account that can write images to that registry; for example:

```
podman login $TARGET_REGISTRY
```

If the registry is insecure, add the following flag to the command: `--tls-verify=false`.

h. Mirror the product images to the target registry.

i. If you are using a portable computer, connect it to the restricted-network environment that contains the local registry.
If you are using portable storage, you already transferred files to a device within the restricted-network environment.

ii. Run the following commands to copy the images to the local registry:

- API Connect:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

- Foundational services:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

- EDB:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

Note: If the local registry is not secured by TLS, or the certificate presented by the local registry is not trusted by your device, add the `--insecure` option to the command.
There might be a slight delay before you see a response to the command.

i. Configure the target cluster.
Now that images have been mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

i. Log in to your Red Hat OpenShift Container Platform cluster:

```
oc login <openshift_url> -u <username> -p <password> -n <namespace>
```

ii. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

```
oc edit image.config.openshift.io/cluster -o yaml
```

and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

```
spec:
  registrySources:
    insecureRegistries:
    - insecure0.svc:5001
    - <TARGET_REGISTRY>
```

If the `insecureRegistries` field does not exist, you can add it.

iii. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry:

- API Connect:

  ```
  oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml
  ```

- Foundational services:

  ```
  oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
  ```

- EDB:

  ```
  oc apply -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/image-content-source-policy.yaml
  ```

iv. Verify that each ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

v. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

Wait for all nodes to be updated before proceeding to the next step.

5. Apply the catalog sources.
Now that you have mirrored images to the target cluster, apply the catalog sources for API Connect and Foundational services. There is no need to apply the catalog source for EDB because the API Connect operator will apply that catalog source in its own namespace when the API Connect operand is created.

In the following steps, replace ***<Architecture>*** with either **amd64** or **s390x** as appropriate for your environment.

a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.4.1
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.3
export CS_ARCH=amd64
```

b. Generate the catalog sources and save them in another directory in case you need to replicate this installation in the future.

i. Get the catalog sources:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Get any architecture-specific catalog sources that you need to back up as well:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.

i. Apply the universal catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

ii. Apply any architecture-specific catalog sources:

```
oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources-linux-${ARCH}.yaml
```

iii. Confirm that the catalog sources were created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

What to do next

Install API Connect following the steps for your deployment type: Deploying on OpenShift and Cloud Pak for Integration.

Installing a two data center deployment with Cloud Pak for Integration

How to deploy a two data center disaster recovery (2DCDR) deployment on OpenShift with Cloud Pak for Integration.

Introduction

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center warm-standby deployment on Kubernetes and OpenShift.

Familiarize yourself with the Cloud Pak for Integration installation instructions linked from Deploying on OpenShift and Cloud Pak for Integration.
Note: During a 2DCDR installation, the management subsystem remains in a **Warning** state until the management subsystems in both data centers synchronize their databases. The management **Warning** status prevents the deployment and registration of the portal, gateway, and analytics subsystems. When the management subsystem databases are synchronized and both in **Ready** state, the deployment and registration of the other subsystems starts.

Prerequisites

The prerequisites for a 2DCDR deployment with Cloud Pak for Integration are as follows.

- The management and portal endpoints must be the same on both data centers.
- The network latency between data centers must be no more than 80 ms.
- The management cluster in each data center must use the same encryption secret.
- The portal cluster in each data center must use the same encryption secret.
- The ingress-ca certificate must be the same on both data centers.
- The API Connect namespace name must be the same in both clusters.
- The APIConnectCluster CR name must be identical on both clusters.

Restrictions:

- API Connect is not supported on a FIPS-enabled environment.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).

- **Planning and initial preparation**
  Decide on endpoint, host, and namespace names. Prepare your Cloud Pak for Integration environments for 2DCDR API Connect.
- **Preparing your active data center**
  Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.
- **Preparing your warm-standby data center**
  Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.
- **Installing API Connect on the active data center**
  Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the `multiSiteHA` configuration to the API Connect YAML.
- **Installing API Connect on the warm-standby data center**
  Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the `multiSiteHA` configuration to the API Connect YAML.

Planning and initial preparation

Decide on endpoint, host, and namespace names. Prepare your Cloud Pak for Integration environments for 2DCDR API Connect.

Procedure

1. Decide on naming. Both data centers must use the same names for:
   - API Connect namespace.
   - API Connect Cluster CR name. Also known as the API Connect instance name, and referred to in this document as `<apic-instance-name>`.
   - Management subsystem endpoints
     - `cloudManagerEndpoint`
     - `apiManagerEndpoint`
     - `platformAPIEndpoint`
     - `consumerAPIEndpoint`
     - `consumerCatalogEndpoint`
   - Portal subsystem endpoints
     - `portalAdminEndpoint`
     - `portalUIEndpoint`

   Important: Each data center must use a different backup path for your management database backups. For portal database backups each data center must use the same backup path. For more information, see Backup and restore requirements for a 2DCDR deployment.
2. Create a namespace for your API Connect deployment in both data centers.
   The API Connect namespace must be the same in both data centers, set it with:

   ```
   oc create ns <namespace>
   ```

3. Install the API Connect operators in both your data centers. See Installing operators. Return here when the operators are installed.
4. Decide which data center will start as the active and which will start as the warm-standby.
5. On the CLI of the active data center, where you run `oc` commands, create a directory called `2dcdr-active-yamls`. On the CLI of the warm-standby data center, create a directory called `2dcdr-ws-yamls`.

What to do next

Proceed to prepare the replication certificates, secrets, and issuers on your active data center Preparing your active data center.

Preparing your active data center

Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.

About this task

All operations are done on the CLI, in the `2dcdr-active-yamls` directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace `<apic-instance-name>` with the name you intend to use for your API Connect Cluster CR, and `<namespace>` with your API Connect namespace name (which will be the same for both Management and Portal subsystems). As decided in Planning and initial preparation.

Procedure

1. Create the encryption key secrets for the Management and Portal subsystems.
   a. Run the following command to create a file that contains a random string, which is used to create the management encryption key secret:

   ```
   cat /dev/urandom | head -c63 | base64 -w0 > mgmt-enc-key.txt
   ```

   b. Run the following command to create the management encryption key secret:

   ```
   oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
   namespace>
   ```

   c. Confirm that the secret was created successfully by running:

   ```
   oc get secrets -n <management namespace> | grep mgmt-encryption-key

   mgmt-encryption-key        Opaque                                1      83s
   ```

   d. Run the following command to create a file that contains a random string, which is used to create the portal encryption key secret:

   ```
   cat /dev/urandom | head -c63 | base64 -w0 > ptl-enc-key.txt
   ```

   e. Run the following command to create the portal encryption key secret:

   ```
   oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
   ```

   f. Confirm that the secret was created successfully by running:

   ```
   oc get secrets -n <portal namespace> | grep ptl-encryption-key

   ptl-encryption-key         Opaque                                1      15s
   ```

2. Create a self-signed issuer.
   a. Create a file that is called `issuer.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

   ```
   apiVersion: cert-manager.io/v1
   kind: Issuer
   metadata:
     name: <apic-instance-name>-self-signed
   spec:
     selfSigned: {}
   ```

   b. Apply this yaml file with:

   ```
   oc apply -f issuer.yaml -n <namespace>
   ```

   c. Verify that the issuer was created with:

   ```
   oc get issuer -n <namespace>

   NAME               READY   AGE
   apic-self-signed   True    25s
   ```

3. Create an ingress-ca certificate:
   a. Create a file that is called `self-signed-issuer-cert.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: <apic-instance-name>-ingress-ca
   spec:
     commonName: ingress-ca
     duration: 87600h0m0s
     isCA: true
     issuerRef:
       kind: Issuer
       name: <apic-instance-name>-self-signed
     renewBefore: 720h0m0s
     privateKey:
       rotationPolicy: Always
     secretName: <apic-instance-name>-ingress-ca
   ```

   b. Apply this yaml file with:

   ```
   oc apply -f self-signed-issuer-cert.yaml -n <namespace>
   ```

   c. Verify that the certificate was created with:

   ```
   oc get cert -n <namespace>

   NAME                          READY   SECRET                        AGE     EXPIRATION
   apic-ingress-ca               True    apic-ingress-ca               11s     2032-08-15T13:01:47Z
   ```

4. Create the ingress issuer.
   a. Create a file `ingress-issuer.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

   ```
   apiVersion: cert-manager.io/v1
   kind: Issuer
   metadata:
     name: <apic-instance-name>-ingress-issuer
   spec:
     ca:
       secretName: <apic-instance-name>-ingress-ca
   ```

b. Apply this yaml file with:

```
oc apply -f ingress-issuer.yaml -n <namespace>
```

c. Verify that the issuer was created with:

```
oc get issuer -n <namespace>
```

```
NAME                  READY   AGE
apic-ingress-issuer   True    20s
```

5. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called `mgmt-tls-client-cert.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-mgmt-replication-client
spec:
  commonName: <apic-instance-name>-mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-mgmt-replication-client
```

   b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

   c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>
```

```
NAME                                          READY   SECRET                                        AGE
EXPIRATION
...
<apic-instance-name>-mgmt-replication-client   True    <apic-instance-name>-mgmt-replication-client   16m     2024-
08-17T13:04:27Z
```

   d. Create a file `ptl-tls-client-cert.yaml` and paste in the following contents, replacing `<apic-instance-name>`:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-ptl-replication-client
spec:
  commonName: <apic-instance-name>-ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-ptl-replication-client
```

   e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

   f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>
```

```
NAME                                          READY   SECRET                                        AGE
EXPIRATION
...
<apic-instance-name>-ptl-replication-client   True    <apic-instance-name>-ptl-replication-client   16m     2024-08-
17T13:04:27Z
```

6. Export the ingress-ca issuer secret.
   The ingress-ca issuer secret must be the same on the warm-standby data center. Export it from the active so that it can be imported on the warm-standby data center.
   a. Run the following command to export the secret to a file called `ca-issuer-secret.yaml`:

```
oc get secret <apic-instance-name>-ingress-ca -o yaml -n <namespace>  > ca-issuer-secret.yaml
```

   b. Edit the `ca-issuer-secret.yaml` file to remove the creationTimestamp, resourceVersion, uid, and managedFields. Remove the labels and annotations sections completely. The contents should look like this:

```
apiVersion: v1
data:
  ca.crt: <long cert string>
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
metadata:
  name: <apic-instance-name>-ingress-ca
  namespace: <namespace>
type: kubernetes.io/tls
```

7. Copy the following files from your **2dcdr-active-yamls** directory to the **2dcdr-ws-yamls** directory in your warm-standby data center.

   ```
   ca-issuer-secret.yaml
   mgmt-enc-key.txt
   ptl-enc-key.txt
   ```

   These files are required to ensure that the ingress-ca and encryption secrets on both sites are the same.
   Tip: To save time during the preparation of your warm-standby data center you can also copy these yaml files:

   ```
   ptl-tls-client-cert.yaml
   mgmt-tls-client-cert.yaml
   ingress-issuer.yaml
   ```

What to do next

Create your secrets, certs, and issuers on your warm-standby data center: Preparing your warm-standby data center.

Preparing your warm-standby data center

Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.

About this task

All operations are done on the CLI, in the **2dcdr-ws-yamls** directory you created in Planning and initial preparation.

In the YAML files and commands that are shown here, replace **<apic-instance-name>** with the name you intend to use for your API Connect Cluster CR, and **<namespace>** with your API Connect namespace name (which will be the same for both Management and Portal subsystems). As decided in Planning and initial preparation.

Procedure

1. Import the ingress-ca issuer secret.
   This secret was created on your active data center here: Export the ingress-ca issuer secret
   a. Copy the **ca-issuer-secret.yaml** file to your warm-standby data center (if not done already).
   b. Create the secret with:

      ```
      oc apply -f ca-issuer-secret.yaml -n <namespace>
      ```

   c. Verify that the secret was created with:

      ```
      oc get secret -n <namespace>
      ```

      ```
      NAME                                                  TYPE                                  DATA   AGE
      <apic-instance-name>-ingress-ca                       kubernetes.io/tls                     3      19h
      ```

2. Create the ingress issuer.
   a. Create a file **ingress-issuer.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

      ```
      apiVersion: cert-manager.io/v1
      kind: Issuer
      metadata:
        name: <apic-instance-name>-ingress-issuer
      spec:
        ca:
          secretName: <apic-instance-name>-ingress-ca
      ```

   b. Apply this yaml file with:

      ```
      oc apply -f ingress-issuer.yaml -n <namespace>
      ```

   c. Verify that the issuer was created with:

      ```
      oc get issuer -n <namespace>
      ```

      ```
      NAME                   READY   AGE
      apic-ingress-issuer    True    20s
      ```

3. Create the encryption key secrets for the Management and Portal subsystems, by using the random string generated on the active data center.
   Use the **mgmt-enc-key.txt** and **ptl-enc-key.txt** files that were copied to your warm-standby data center here: Copy keys to warm-standby.
   a. Run the following command to create the management encryption key secret:

      ```
      oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
      namespace>
      ```

   b. Confirm that the secret was created successfully by running:

      ```
      oc get secrets -n <management namespace> | grep mgmt-encryption-key
      ```

      ```
      mgmt-encryption-key        Opaque                                1      83s
      ```

   c. Run the following command to create the portal encryption key secret:

      ```
      oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
      ```

   d. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key

ptl-encryption-key         Opaque                                1      15s
```

4. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called **mgmt-tls-client-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-mgmt-replication-client
spec:
  commonName: <apic-instance-name>-mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-mgmt-replication-client
```

   b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

   c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>

NAME                                          READY   SECRET                                        AGE
EXPIRATION
...
<apic-instance-name>-mgmt-replication-client   True    <apic-instance-name>-mgmt-replication-client   16m     2024-
08-17T13:04:27Z
```

   d. Create a file **ptl-tls-client-cert.yaml** and paste in the following contents, replacing **<apic-instance-name>**:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: <apic-instance-name>-ptl-replication-client
spec:
  commonName: <apic-instance-name>-ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: <apic-instance-name>-ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: <apic-instance-name>-ptl-replication-client
```

   e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

   f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>

NAME                                          READY   SECRET                                        AGE
EXPIRATION
...
<apic-instance-name>-ptl-replication-client   True    <apic-instance-name>-ptl-replication-client   16m     2024-08-
17T13:04:27Z
```

What to do next

Install API Connect in your active data center: Installing API Connect on the active data center.

Installing API Connect on the active data center

Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the **multiSiteHA** configuration to the API Connect YAML.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get secrets -n <namespace> | grep <apic-instance-name>
<apic-instance-name>-ingress-ca               kubernetes.io/tls                     3      3d21h
<apic-instance-name>-mgmt-replication-client  kubernetes.io/tls                     3      3d21h
<apic-instance-name>-ptl-replication-client   kubernetes.io/tls                     3      3d21h

oc get certs -n <namespace> | grep <apic-instance-name>
<apic-instance-name>-ingress-ca               True    <apic-instance-name>-ingress-ca               3d21h   2032-08-
15T13:01:47Z
<apic-instance-name>-mgmt-replication-client  True    <apic-instance-name>-mgmt-replication-client  3d21h   2024-08-
```

```
17T13:04:27Z
<apic-instance-name>-ptl-replication-client    True    <apic-instance-name>-ptl-replication-client    3d21h   2024-08-
17T13:04:26Z

oc get issuer -n <namespace> | grep <apic-instance-name>
<apic-instance-name>-ingress-issuer    True    3d21h
<apic-instance-name>-self-signed       True    3d21h
```

Where **<apic-instance-name>** is the name you intend to use for your API Connect cluster CR, and **<namespace>** is the namespace you created for API Connect.

About this task

In the yaml files that are shown here, replace **<apic-instance-name>** with the name you intend to use for your API Connect Cluster CR. As decided in Planning and initial preparation. Set **<active data center ingress domain>** and **<warm-standby data center ingress domain>** to their appropriate values, which can be determined by running this command in each data center:

```
oc get ingresses.config/cluster -o jsonpath={.spec.domain}
```

Procedure

1. Follow the API Connect installation steps using the Platform UI, as described in the Cloud Pak for Integration documentation https://www.ibm.com/docs/en/cloud-paks/cp-integration. At the point where you specify the configuration properties of your API Connect instance, switch to the YAML tab so you can edit the YAML directly.
   Remember: Use the same **<apic-instance-name>** value when you specify the API Connect instance name in the Cloud Pak for Integration Platform UI.
2. Add the **management.encryptionSecret.secretName** property, and the **management.multiSiteHA** section to the YAML file inside the **spec** section.

   ```
   management:
     ...
     encryptionSecret:
       secretName: mgmt-encryption-key
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
         hosts:
         - name: mgmt-replication.<active data center ingress domain>
           secretName: <apic-instance-name>-mgmt-replication-server
       replicationPeerFQDN: mgmt-replication.<warm-standby data center ingress domain>
       tlsClient:
         secretName: <apic-instance-name>-mgmt-replication-client
   ```

   Also set the **management.<endpoint>.hosts.name** properties to the endpoint URLs you decided on in Planning and initial preparation.

3. Add the **portal.encryptionSecret.secretName** property, and the **portal.multiSiteHA** section to the YAML file inside the **spec** section.

   ```
   portal:
     ...
     encryptionSecret:
       secretName: ptl-encryption-key
     multiSiteHA:
       mode: active
       replicationEndpoint:
         annotations:
           cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
         hosts:
         - name: ptl-replication.<active data center ingress domain>
           secretName: <apic-instance-name>-ptl-replication-server
       replicationPeerFQDN: ptl-replication.<warm-standby data center ingress domain>
       tlsClient:
         secretName: <apic-instance-name>-ptl-replication-client
   ```

   Also set the **portal.<endpoint>.hosts.name** properties to the endpoint URLs you decided on in Planning and initial preparation.

4. Continue the installation steps as described in Deploying on OpenShift and Cloud Pak for Integration.

Results

Confirm that the management subsystem is ready, but in **Warning** state with **oc get mgmt**:

```
oc get mgmt -n <namespace>

NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

oc get mgmt -n <namespace> -o yaml

...
status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

The management CR is expected to report the status of **Warning** until the warm-standby management subsystem is deployed, and both management subsystems complete data replication. When you see the status message "Management is ready. HA Status Warning - see HAStatus in CR for details", you can move on to Installing API Connect on the warm-standby data center.
Note: The portal, analytics, and gateway subsystems are not deployed until the management replication is complete and the management CRs in both data centers report the following:

```
oc get mgmt -n <namespace>

NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Running   10.0.8.0-0   10.0.8.0-0           Management is ready. HA status Ready - see HAStatus in CR for
details               8m59s

oc get mgmt -n <namespace> -o yaml

...
status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

What to do next

Extract the Cloud Pak for Integration credentials, and copy them to your warm-standby data center:

1. Identify the secret that contains the Cloud Pak for Integration credentials:

   ```
   oc -n <namespace> get secrets | grep cp4i-creds
   ```

2. Extract the credentials to a file:

   ```
   oc get secret <secret name>  -o json | jq
   'del(.metadata.creationTimestamp,.metadata.labels,.metadata.resourceVersion,.metadata.uid,.metadata.ownerReferences)' >
   cp4i-creds.json
   ```

   where *<secret name>* is the secret you identified in step 1.

3. Copy the cp4i-creds.json file to the warm-standby data center.

Install API Connect on your warm-standby data center: Installing API Connect on the warm-standby data center.

Installing API Connect on the warm-standby data center

Follow the installation steps for API Connect described in the Cloud Pak for Integration documentation, adding the **multiSiteHA** configuration to the API Connect YAML.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get certificate -n <namespace> | grep <apic-instance-name>
NAME                            READY   SECRET                          AGE     EXPIRATION
apic-mgmt-replication-client    True    apic-mgmt-replication-client    57s   2024-08-24T09:45:03Z
apic-ptl-replication-client     True    apic-ptl-replication-client     45s   2024-08-24T09:45:17Z

[root@api.iaincp4ilarge2.cp.fyre.ibm.com ~]# oc get secrets  -n <namespace> | grep <apic-instance-name>
NAME                                TYPE                                  DATA   AGE
apic-ingress-ca                     kubernetes.io/tls                     3      4m6s
apic-mgmt-replication-client        kubernetes.io/tls                     3      2m40s
apic-ptl-replication-client         kubernetes.io/tls                     3      2m26s

[root@api.iaincp4ilarge2.cp.fyre.ibm.com ~]# oc get issuer -n <namespace> | grep <apic-instance-name>
NAME                  READY   AGE
apic-ingress-issuer   True    4m8s
```

Where **<apic-instance-name>** is the name you intend to use for your API Connect cluster CR, and **<namespace>** is the namespace you created for API Connect.

About this task

In the yaml files that are shown here, replace **<apic-instance-name>** with the name you intend to use for your API Connect Cluster CR. As decided in Planning and initial preparation. Set **<active data center ingress domain>** and **<warm-standby data center ingress domain>** to their appropriate values, which can be determined by running this command in each data center:

```
oc get ingresses.config/cluster -o jsonpath={.spec.domain}
```

Procedure

1. Apply the Cloud Pak for Integration credentials that you copied from your active data center (see Copy active credentials).

   ```
   oc -n <namespace> apply -f cp4i-creds.json
   ```

2. Follow the API Connect installation steps using the Platform UI, as described in the Cloud Pak for Integration documentation https://www.ibm.com/docs/en/cloud-paks/cp-integration. At the point where you specify the configuration properties of your API Connect instance, switch to the YAML tab so you can edit the YAML directly.
   Remember: Use the same **<apic-instance-name>** value when you specify the API Connect instance name in the Cloud Pak for Integration Platform UI.
3. Add the **management.encryptionSecret.secretName** property, and the **management.multiSiteHA** section to the YAML file inside the **spec** section.

```
management:
  ...
  encryptionSecret:
    secretName: mgmt-encryption-key
  multiSiteHA:
    mode: passive
    replicationEndpoint:
      annotations:
        cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
      hosts:
      - name: mgmt-replication.<warm-standby data center ingress domain>
        secretName: <apic-instance-name>-mgmt-replication-server
    replicationPeerFQDN: mgmt-replication.<active data center ingress domain>
    tlsClient:
      secretName: <apic-instance-name>-mgmt-replication-client
```

   Note: Warm-standby is referred to as 'passive' in the CR YAML.
   Also set the **management.<endpoint>.hosts.name** properties to the endpoint URLs you decided on in Planning and initial preparation.

4. Add the **portal.encryptionSecret.secretName** property, and the **portal.multiSiteHA** section to the YAML file inside the **spec** section.

```
portal:
  ...
  encryptionSecret:
    secretName: ptl-encryption-key
  multiSiteHA:
    mode: passive
    replicationEndpoint:
      annotations:
        cert-manager.io/issuer: <apic-instance-name>-ingress-issuer
      hosts:
      - name: ptl-replication.<warm-standby data center ingress domain>
        secretName: <apic-instance-name>-ptl-replication-server
    replicationPeerFQDN: ptl-replication.<active data center ingress domain>
    tlsClient:
      secretName: <apic-instance-name>-ptl-replication-client
```

   Also set the **portal.<endpoint>.hosts.name** properties to the endpoint URLs you decided on in Planning and initial preparation.

5. Continue the installation steps as described in Deploying on OpenShift and Cloud Pak for Integration.

Results

Installation can take around 1 hour to complete.

While the management subsystems on the warm-standby and active data centers are synchronizing, the management status reports **Warning**, and the **haStatus** reports **pending**:

```
oc get mgmt -n <namespace>
```

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

When the management database replication between sites is complete, the management status reports **Running**, and **status.haStatus** reports **Ready**:

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Running   10.0.8.0-0   10.0.8.0-0           Management is ready. HA status Ready - see HAStatus in CR for
details               8m59s

status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

After the management subsystems in the active and warm-standby sites are synchronized, the other subsystems are deployed. Verify on both active and warm-standby sites that all subsystems reach **Running** state:

```
oc get all -n <namespace>
...
NAME                                                              READY   STATUS    VERSION    RECONCILED VERSION   AGE
analyticscluster.analytics.apiconnect.ibm.com/apis-minimum-a7s    n/n     Running   10.0.8.0   10.0.8.0-1281        27m

NAME                                                 READY   STATUS   VERSION    RECONCILED VERSION   AGE
apiconnectcluster.apiconnect.ibm.com/apis-minimum    n/n     Ready    10.0.8.0   10.0.8.0-1281        2d20h

NAME                                                  PHASE     READY   SUMMARY                              VERSION    AGE

NAME                                                  READY   STATUS    VERSION    RECONCILED VERSION   AGE
portalcluster.portal.apiconnect.ibm.com/apis-minimum-ptl   n/n     Running   10.0.8.0   10.0.8.0-1281        27m
```

Note: The warm-standby site has fewer **managementcluster** pods than the active site.
If the management database replication between sites fails for any reason other than because an install or upgrade is in progress, the **haStatus** output shows the reason, for example::

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "PeerNotReachable"
    }
```

If the warning persists, see Troubleshooting a two data center deployment.

You can validate that your portal deployments are synchronizing by running **oc get pods** on both the active and warm-standby data centers. Confirm that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the **Ready** state.

For additional replication verification checks, see Verifying replication between data centers. It is recommended to run a test failover, and confirm that all of the expected data is present and correct on the newly active site. See Failing over to the warm-standby.

What to do next

Configure your deployment: Cloud Manager configuration checklist.
Important: It is strongly recommended to take complete backups of both sites, for disaster recovery in case the API Connect installation in both data centers is lost, or if a replication failure occurs. Complete backups consist of your infrastructure configuration backup and your subsystem database backups. See Backup and restore requirements for a 2DCDR deployment.

Installing a two data center deployment on OpenShift

How to deploy a two data center disaster recovery (2DCDR) deployment on OpenShift.

Introduction

Ensure that you understand the concepts of 2DCDR in API Connect. For more information, see Two data center warm-standby deployment on Kubernetes and OpenShift.

Familiarize yourself with the OpenShift installation instructions linked from Deploying on OpenShift and Cloud Pak for Integration.

Note: 2DCDR is not supported on OpenShift where the top-level CR is used. For 2DCDR on OpenShift, you must install API Connect as individual subsystems. See Installing API Connect in a single namespace on OpenShift and Installing API Connect subsystems in different namespaces or environments on OpenShift.

Prerequisites

The prerequisites for a 2DCDR deployment on OpenShift are as follows.

- The management and portal endpoints must be the same on both data centers.
- The network latency between data centers must be no more than 80 ms.
- The management cluster in each data center must use the same encryption secret.
- The portal cluster in each data center must use the same encryption secret.
- The ingress-ca certificate must be the same on both data centers.

Restrictions:

- API Connect is not supported on a FIPS-enabled environment.

- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).

- **Planning and initial preparation**
  Decide on endpoint names. Prepare your OpenShift environments for 2DCDR API Connect.
- **Preparing your active data center**
  Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.
- **Preparing your warm-standby data center**
  Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.
- **Installing API Connect on the active data center**
  Add the `multiSiteHA` configuration to the API Connect Management and Portal CR YAML files before they are applied.
- **Installing API Connect on the warm-standby data center**
  Add the `multiSiteHA` configuration to the API Connect Management and Portal YAML files before they are applied.

Planning and initial preparation

Decide on endpoint names. Prepare your OpenShift environments for 2DCDR API Connect.

Procedure

1. Decide on naming. Both data centers must use the same names for:
   - Management subsystem endpoints
     - `cloudManagerEndpoint`
     - `apiManagerEndpoint`
     - `platformAPIEndpoint`
     - `consumerAPIEndpoint`
     - `consumerCatalogEndpoint`
   - Portal subsystem endpoints
     - `portalAdminEndpoint`
     - `portalUIEndpoint`

   Each data center must have a different `siteName`. For example, `dallas` in data center 1, and `raleigh` in data center 2. The site name can contain only `a-z` and `0-9` characters. You set `siteName` in the `ManagementCluster` and `PortalCluster` CRs when the subsystems are first deployed. You cannot change the name after deployment. If you don't specify `siteName` at first deployment, a random `siteName` is created for you.

   Important: Each data center must use a different backup path for your Management backups. For portal backups each data center must use the same backup path. For more information, see Backup and restore requirements for a 2DCDR deployment.
2. Install the API Connect operators in both your data centers. See Installing operators for a single namespace API Connect installation or Installing operators for a multi namespace API Connect installation, depending on whether all your API Connect subsystems are to be in the same namespace or not. Return here when the operators are installed.
3. If not already done, create namespaces for your API Connect subsystems in both data centers.

   ```
   oc create ns <namespace>
   ```

   the data centers do not have to use the same namespace name.
4. Decide which data center will start as the active and which will start as the warm-standby.
5. On the CLI of the active data center, where you run `oc` commands, create a directory called `2dcdr-active-yamls`. On the CLI of the warm-standby data center, create a directory called `2dcdr-ws-yamls`.

What to do next

Proceed to prepare the replication certificates, secrets, and issuers on your active data center Preparing your active data center.

Preparing your active data center

Create the secrets, certificates, and issuers that are needed for your active data center to replicate with the warm-standby.

About this task

All operations are done on the CLI, in the `2dcdr-active-yamls` directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace `<namespace>` with the name of the corresponding subsystem namespace.

Procedure

1. Create the encryption key secrets for the Management and Portal subsystems.
   a. Run the following command to create a file that contains a random string, which is used to create the management encryption key secret:

      ```
      cat /dev/urandom | head -c63 | base64 -w0 > mgmt-enc-key.txt
      ```

   b. Run the following command to create the management encryption key secret:

      ```
      oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management namespace>
      ```

   c. Confirm that the secret was created successfully by running:

```
oc get secrets -n <management namespace> | grep mgmt-encryption-key

mgmt-encryption-key        Opaque                                1      83s
```

d. Run the following command to create a file that contains a random string, which is used to create the portal encryption key secret:

```
cat /dev/urandom | head -c63 | base64 -w0 > ptl-enc-key.txt
```

e. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

f. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key

ptl-encryption-key         Opaque                                1      15s
```

2. If all your API Connect subsystems are to be installed in the same namespace, then create your certificates, issuers, and secrets as described here: Setting up a certificate issuer. Return here when complete, do not proceed to install the subsystems.
3. If your API Connect subsystems are to be installed in different namespaces, then create your certificates, issuers, and secrets for your Management subsystem as described here Create Management subsystem issuers and secrets. For your Portal subsystem, follow the steps here Create Portal subsystem issuers and secretes. Return here when complete, do not proceed to install either subsystem.
4. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called `mgmt-tls-client-cert.yaml` and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: mgmt-replication-client
spec:
  commonName: mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: mgmt-replication-client
```

   b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

   c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>

NAME                       READY   SECRET                     AGE     EXPIRATION
...
mgmt-replication-client    True    mgmt-replication-client    16m     2024-08-17T13:04:27Z
```

   d. Create a file `ptl-tls-client-cert.yaml` and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ptl-replication-client
spec:
  commonName: ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: ptl-replication-client
```

   e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

   f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>

NAME                       READY   SECRET                     AGE     EXPIRATION
...
ptl-replication-client     True    ptl-replication-client     16m     2024-08-17T13:04:27Z
```

5. Export the ingress-ca issuer secret.
   The ingress-ca issuer secret must be the same on the warm-standby data center. Export it from the active so that it can be imported on the warm-standby data center.
   Note: If you are deploying API Connect subsystems in different namespaces, then you export the Management subsystem ingress-ca secret.
   a. Run the following command to export the secret to a file called `ca-issuer-secret.yaml`:

```
oc get secret ingress-ca -o yaml -n <management namespace>  > ca-issuer-secret.yaml
```

   b. Edit the `ca-issuer-secret.yaml` file to remove the creationTimestamp, resourceVersion, uid, namespace, and managedFields. Remove the labels and annotations sections completely. The resulting contents should look like this:

```
apiVersion: v1
data:
  ca.crt: <long cert string>
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
metadata:
  name: ingress-ca
type: kubernetes.io/tls
```

6. Copy the following files from your **2dcdr-active-yamls** directory to the **2dcdr-ws-yamls** directory in your warm-standby data center.

   ca-issuer-secret.yaml
   mgmt-enc-key.txt
   ptl-enc-key.txt

   These files are required to ensure that the ingress-ca and encryption secrets on both sites are the same.
   Tip: To save time during the preparation of your warm-standby data center you can also copy these yaml files:

   ptl-tls-client-cert.yaml
   mgmt-tls-client-cert.yaml

7. If you are installing the Portal subsystem in a different namespace to the Management subsystem on the active data center, use the **ca-issuer-secret.yaml** file to create the issuer in your portal namespace. Follow the 'Before you begin steps here: Create issuer. Do not proceed to install the Portal subsystem after creating the issuer.

What to do next

Prepare your warm-standby data center Preparing your warm-standby data center.

Preparing your warm-standby data center

Create the secrets, certificates, and issuers that are needed for your warm-standby data center to replicate with the active.

About this task

All operations are done on the CLI, in the **2dcdr-ws-yamls** directory you created in Planning and initial preparation.

In the yaml files and commands that are shown here, replace **<namespace>** with the name of the corresponding subsystem namespace.

Procedure

1. Import the ingress-ca issuer secret.
   This secret was created on your active data center here: Preparing your active data center
   a. If you did not do it as part of Preparing your active data center, copy the **ca-issuer-secret.yaml** file to your warm-standby data center.
   b. Create the secret with:

      ```
      oc apply -f ca-issuer-secret.yaml -n <namespace>
      ```

   c. Verify that the secret was created with:

      ```
      oc get secret -n <namespace>
      ```

      ```
      NAME                          TYPE                                DATA   AGE
      ingress-ca                    kubernetes.io/tls                   3      19h
      ```

   d. If your Portal subsystem is in a different namespace in your warm-standby data center, then repeat the **oc apply** operation against the portal namespace.
2. Create a file that is called **warm-standby-certs.yaml** and paste in:

```

      app.kubernetes.io/managed-by: "ibm-apiconnect"
      app.kubernetes.io/name: "gateway-peering"
```

3. Apply this file by running against your Management subsystem namespace:

```
oc apply -f warm-standby-certs.yaml -n <namespace>
```

4. Verify that the certificates, secrets, and issuers were created with:

```
oc get secrets -n <namespace>
NAME                          TYPE                                  DATA   AGE
analytics-ingestion-client    kubernetes.io/tls                     3      12s
gateway-client-client         kubernetes.io/tls                     3      21s
gateway-peering               kubernetes.io/tls                     3      11s
gateway-service               kubernetes.io/tls                     3      21s
ingress-ca                    kubernetes.io/tls                     3      18m
portal-admin-client           kubernetes.io/tls                     3      17s

oc get certificates -n <namespace>
NAME                          READY   SECRET                        AGE     EXPIRATION
analytics-ingestion-client    True    analytics-ingestion-client    2m18s   2024-09-04T12:27:38Z
gateway-client-client         True    gateway-client-client         2m19s   2024-09-04T12:27:28Z
gateway-peering               True    gateway-peering               2m17s   2024-09-04T12:27:39Z
gateway-service               True    gateway-service               2m18s   2024-09-04T12:27:28Z
```

```
portal-admin-client          True    portal-admin-client          2m19s   2024-09-04T12:27:33Z

oc get issuers -n <namespace>
NAME                 READY   AGE
ingress-issuer       True    18m
selfsigning-issuer   True    2m42s
```

5. If your Portal subsystem is in a different namespace in your warm-standby data center, then to create your certificates, issuers, and secrets in the Portal subsystem namespace:
   a. Create a file that is called `warm-standby-ptl-certs.yaml` and paste in:

```
#
# Licensed under the Apache License, Version 2.0 (the "License");
# you may not use this file except in compliance with the License.
# You may obtain a copy of the License at
#
#     http://www.apache.org/licenses/LICENSE-2.0
#
# Unless required by applicable law or agreed to in writing, software
# distributed under the License is distributed on an "AS IS" BASIS,
# WITHOUT WARRANTIES OR CONDITIONS OF ANY KIND, either express or implied.
# See the License for the specific language governing permissions and
# limitations under the License.
#

---

apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: selfsigning-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "selfsigning-issuer"
  }
spec:
  selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
  name: ingress-issuer
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "ingress-issuer"
  }
spec:
  ca:
    secretName: ingress-ca
```

   b. Apply this file to your Portal subsystem namespace:

```
oc apply -f warm-standby-certs.yaml -n <namespace>
```

   c. Verify that your issuers and secrets were created successfully:

```
oc get issuers -n <portal namespace>
NAME                 READY   AGE
ingress-issuer       True    43s
selfsigning-issuer   True    43s

oc get secrets -n <portal namespace>
NAME                       TYPE                                  DATA   AGE
ingress-ca                 kubernetes.io/tls                     3      4m18s
```

6. Create the encryption key secrets for the Management and Portal subsystems, by using the random string generated on the active data center.
   Use the `mgmt-enc-key.txt` and `ptl-enc-key.txt` files that were copied to your warm-standby data center when you followed Preparing your active data center.
   a. Run the following command to create the management encryption key secret:

```
oc create secret generic mgmt-encryption-key --from-file=encryption_secret.bin=mgmt-enc-key.txt -n <management
namespace>
```

   b. Confirm that the secret was created successfully by running:

```
oc get secrets -n <management namespace> | grep mgmt-encryption-key

mgmt-encryption-key        Opaque                                1      83s
```

   c. Run the following command to create the portal encryption key secret:

```
oc create secret generic ptl-encryption-key --from-file=encryption_secret=ptl-enc-key.txt -n <portal namespace>
```

   d. Confirm that the secret was created successfully by running:

```
oc get secrets -n <portal namespace> | grep ptl-encryption-key

ptl-encryption-key         Opaque                                1      15s
```

7. Create the TLS client replication certificates for Management and Portal.
   a. Create a yaml file that is called `mgmt-tls-client-cert.yaml` and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: mgmt-replication-client
spec:
  commonName: mgmt-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: mgmt-replication-client
```

b. Apply this yaml file with:

```
oc apply -f mgmt-tls-client-cert.yaml -n <management namespace>
```

c. Verify that the certificate was created with:

```
oc get certs -n <management namespace>

NAME                       READY   SECRET                     AGE     EXPIRATION
...
mgmt-replication-client    True    mgmt-replication-client    16m     2024-08-17T13:04:27Z
```

d. Create a file `ptl-tls-client-cert.yaml` and paste in the following contents:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ptl-replication-client
spec:
  commonName: ptl-replication-client
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: ptl-replication-client
```

e. Apply this yaml file with:

```
oc apply -f ptl-tls-client-cert.yaml -n <portal namespace>
```

f. Verify that the certificate was created with:

```
oc get certs -n <portal namespace>

NAME                       READY   SECRET                     AGE     EXPIRATION
...
ptl-replication-client     True    ptl-replication-client     16m     2024-08-17T13:04:27Z
```

What to do next

Install API Connect on your active data center Installing API Connect on the active data center.

Installing API Connect on the active data center

Add the **multiSiteHA** configuration to the API Connect Management and Portal CR YAML files before they are applied.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get secrets -n <namespace>
ingress-ca                kubernetes.io/tls                     3      3d21h
mgmt-replication-client   kubernetes.io/tls                     3      3d21h
ptl-replication-client    kubernetes.io/tls                     3      3d21h

oc get certs -n <namespace>
ingress-ca                True    ingress-ca                3d21h   2032-08-15T13:01:47Z
mgmt-replication-client   True    mgmt-replication-client   3d21h   2024-08-17T13:04:27Z
ptl-replication-client    True    ptl-replication-client    3d21h   2024-08-17T13:04:26Z

oc get issuer -n <namespace>
ingress-issuer   True    3d21h
self-signed      True    3d21h
```

Where **<namespace>** are the namespaces you created for API Connect.
Note: If you have separate namespaces for Management and Portal subsystems, then run the check in both namespaces. You should not see the **mgmt-replication-client** in the portal namespace, nor the **ptl-replication-client** in the management namespace.

Procedure

1. Follow these steps for installing the Management subsystem on OpenShift Installing the management subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **mgmt_cr.yaml** file:

```
  siteName: <dc1 site name>
  encryptionSecret:
    secretName: mgmt-encryption-key
  multiSiteHA:
    mode: active
    replicationEndpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: mgmt-replication.<active data center ingress domain>
        secretName: mgmt-replication-server
    replicationPeerFQDN: mgmt-replication.<warm-standby data center ingress domain>
    tlsClient:
      secretName: mgmt-replication-client
```

   where
   - **<dc1 site name>** is the site name for this data center, as decided in Planning and initial preparation.
   - **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

   Note: If you are installing the Management subsystem in a separate namespace, these same steps apply.
2. Apply the update **mgmt_cr.yaml** file as directed in Installing the management subsystem in a shared namespace. You can monitor the deployment with:

```
oc get ManagementCluster -n <management namespace>
NAME         READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE AGE
management   n/n   Running   10.0.8.0   10.0.8.0-1281        Management is ready. HA status Warning - see HAStatus in CR
for details 74m
```

3. Follow these steps for installing the Portal subsystem on OpenShift Installing the portal subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **portal_cr.yaml** file.

```
  siteName: <dc1 site name>
  encryptionSecret:
    secretName: ptl-encryption-key
  multiSiteHA:
    mode: active
    replicationEndpoint:
      annotations:
        cert-manager.io/issuer: ingress-issuer
      hosts:
      - name: ptl-replication.<active data center ingress domain>
        secretName: ptl-replication-server
    replicationPeerFQDN: ptl-replication.<warm-standby data center ingress domain>
    tlsClient:
      secretName: ptl-replication-client
```

   where
   - **<dc1 site name>** is the site name for this data center, as decided in Planning and initial preparation.
   - **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

   Note: If you are installing the Portal subsystem in a separate namespace, these same steps apply.
4. Apply the updated **portal_cr.yaml** file as directed in Installing the portal subsystem in a shared namespace.

```
oc get PortalCluster -n <portal namespace>
NAME     READY   STATUS    VERSION    RECONCILED VERSION   AGE
portal   6/6     Running   10.0.8.0   10.0.8.0-1281        49m
```

Results

Confirm that the management subsystem is ready, but in **Warning** state with **oc get mgmt**:

```
oc get mgmt -n <namespace>
```

```
NAME         READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management   n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s
```

```
oc get mgmt -n <namespace> -o yaml
```

```
...
status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

The management CR is expected to report the status of **Warning** until the warm-standby management subsystem is deployed, and both management subsystems complete data replication. When you see the status message "Management is ready. HA Status Warning - see HAStatus in CR for details", you can move on to Installing API Connect on the warm-standby data center.

What to do next

Install API Connect in your warm-standby data center Installing API Connect on the warm-standby data center.

Deploy your Gateway and Analytics subsystems in your active data center. For shared namespace: Installing API Connect in a single namespace on OpenShift or multiple namespaces: Installing API Connect subsystems in different namespaces or environments on OpenShift.

Installing API Connect on the warm-standby data center

Add the **multiSiteHA** configuration to the API Connect Management and Portal YAML files before they are applied.

Before you begin

Verify that all the secrets, certificates, and issuers are ready:

```
oc get secrets -n <namespace>
ingress-ca                kubernetes.io/tls                     3      3d21h
mgmt-replication-client   kubernetes.io/tls                     3      3d21h
ptl-replication-client    kubernetes.io/tls                     3      3d21h

oc get certs -n <namespace>
mgmt-replication-client   True    mgmt-replication-client   3d21h   2024-08-17T13:04:27Z
ptl-replication-client    True    ptl-replication-client    3d21h   2024-08-17T13:04:26Z

oc get issuer -n <namespace>
ingress-issuer   True    3d21h
self-signed      True    3d21h
```

Where **<namespace>** are the namespaces you created for API Connect.
Note: If you have separate namespaces for Management and Portal subsystems, then run the check in both namespaces. You should not see the **mgmt-replication-client** in the portal namespace, nor the **ptl-replication-client** in the management namespace.

Procedure

1. Follow these steps for installing the Management subsystem on OpenShift Installing the management subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **mgmt_cr.yaml** file:

   ```
   siteName: <dc2 site name>
   encryptionSecret:
     secretName: mgmt-encryption-key
   multiSiteHA:
     mode: passive
     replicationEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: mgmt-replication.<warm-standby data center ingress domain>
         secretName: mgmt-replication-server
     replicationPeerFQDN: mgmt-replication.<active data center ingress domain>
     tlsClient:
       secretName: mgmt-replication-client
   ```

   where
   - **<dc2 site name>** is the site name for this data center, as decided in Planning and initial preparation.
   - **<active data center ingress domain>** and **<warm-standby data center ingress domain>** can be determined by running the command **oc get ingresses.config/cluster -o jsonpath={.spec.domain}** in each data center.

   Note: If you are installing the Management subsystem in a separate namespace, these same steps apply.
   Remember: Make sure that the management endpoints are set the same as for your active data center deployment.
2. Apply the update **mgmt_cr.yaml** file as directed in Installing the management subsystem in a shared namespace. Monitor the deployment, but note that on the warm-standby there are fewer pods than on the active:

   ```
   oc get ManagementCluster -n <namespace>

   NAME          READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE      AGE
   management    n/n     Running   10.0.8.0   10.0.8.0-1281        Management is ready. HA Status Warning - see HAStatus in CR
   for details      62m
   ```

3. Follow these steps for installing the Portal subsystem on OpenShift Installing the portal subsystem in a shared namespace, but add the **encryptionSecret** and **multiSiteHA** section to the **portal_cr.yaml** file.

   ```
   siteName: <dc2 site name>
   encryptionSecret:
     secretName: ptl-encryption-key
   multiSiteHA:
     mode: passive
     replicationEndpoint:
       annotations:
         cert-manager.io/issuer: ingress-issuer
       hosts:
       - name: ptl-replication.<warm-standby data center ingress domain>
         secretName: ptl-replication-server
     replicationPeerFQDN: ptl-replication.<warm-standby data center ingress domain>
     tlsClient:
       secretName: ptl-replication-client
   ```

where

- `<dc2 site name>` is the site name for this data center, as decided in Planning and initial preparation.
- `<active data center ingress domain>` and `<warm-standby data center ingress domain>` can be determined by running the command `oc get ingresses.config/cluster -o jsonpath={.spec.domain}` in each data center.

Remember: Make sure that the portal endpoints are set the same as for your active data center deployment.

4. Apply the updated `portal_cr.yaml` file as directed in Installing the portal subsystem in a shared namespace.

```
oc get PortalCluster -n <namespace>
NAME     READY   STATUS    VERSION    RECONCILED VERSION   AGE
portal   6/6     Running   10.0.8.0   10.0.8.0-1281        47m
```

Results

While the management subsystems on the warm-standby and active data centers are synchronizing their databases, the management status reports `Warning`, and the `haStatus` reports `pending`:

```
oc get mgmt -n <namespace>

NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

oc get mgmt -n <namespace> -o yaml

...
status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working, install or upgrade in progress.",
      "reason": "na",
      "status": "True",
      "type": "Pending"
    }
```

When the management database replication between sites is complete, the management status reports `Running`, and `status.haStatus` reports `Ready`:

```
oc get mgmt -n <namespace>

NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Running   10.0.8.0-0   10.0.8.0-0           Management is ready. HA status Ready - see HAStatus in CR for
details               8m59s

oc get mgmt -n <namespace> -o yaml

...
status:
  haStatus
  {
    "lastTransitionTime": "2023-03-31T19:47:08Z",
    "message": "Replication is working",
    "reason": "na",
    "status": "True",
    "type": "Ready"
  }
```

If the management database replication between sites fails for any reason other than because an install or upgrade is in progress, the `haStatus` output shows the reason, for example::

```
NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

status:
  haStatus
    {
      "lastTransitionTime": "2023-12-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "PeerNotReachable"
    }
```

If the warning persists, see Troubleshooting a two data center deployment.
You can validate that your portal deployments are synchronizing by running `oc get pods` on both the active and warm-standby data centers. Confirm that the number and names of the pods all match (the UUIDs in the names might be different on each site), and that all are in the `Ready` state.

For additional replication verification checks, see Verifying replication between data centers. It is recommended to run a test failover, and confirm that all of the expected data is present and correct on the newly active site. See Failing over to the warm-standby.

What to do next

Deploy your Gateway and Analytics subsystems for shared namespace: Installing API Connect in a single namespace on OpenShift or multiple namespaces: Installing API Connect subsystems in different namespaces or environments on OpenShift

Configure your deployment: Cloud Manager configuration checklist, and complete a test failover to verify that your data replicated to the warm-standby. See Failing over to the warm-standby for details.

Important: It is strongly recommended to take complete backups of both sites, for disaster recovery in case the API Connect installation in both data centers is lost, or if a replication failure occurs. Complete backups consist of your infrastructure configuration backup and your subsystem database backups. See Backup and restore requirements for a 2DCDR deployment.

Enable additional features post-install

After installing API Connect, you can enable additional features that are related to inter-subsystem communication.

- **Enable management CA verification on REST API calls**
  Enable the portal and gateway to validate the management subsystem's REST API server certificates.
- **Enable JWT security and disable mTLS between subsystems**
  Postinstallation steps to enable JWT security and disable mTLS between subsystems.

Enable management CA verification on REST API calls

Enable the portal and gateway to validate the management subsystem's REST API server certificates.

About this task

After you install API Connect, you can enable the portal and gateway to verify the REST API server certificate when they make calls to the REST API. The gateway and portal subsystems make calls to the management subsystem REST API during their normal operations. The gateway makes calls to the platform REST API, and the portal makes calls to the platform REST API and the consumer REST API. To verify the CA certificates of the REST API endpoints, enter the secret names of the CA certificates into the portal and gateway CRs.
Note:
If you are not sure of the secret names, follow these steps to determine their names:

1. Check the management subsystem CR with `oc describe mgmt`, and identify the issuer of the platform and consumer API endpoints:

```
oc describe mgmt

...
Platform API Endpoint:
    Annotations:
      cert-manager.io/issuer:               <instance name>-ingress-issuer
...
  Consumer API Endpoint:
    Annotations:
      cert-manager.io/issuer:               <instance name>-ingress-issuer
```

2. Describe the issuer with `oc describe issuer`, and identify the secret name:

```
oc describe issuer <instance name>-ingress-issuer
...
Spec:
  Ca:
    Secret Name:  <instance name>-ingress-ca
...
```

Note: If you are using `in-cluster` communication (see In-cluster service communication between subsystems), then the portal and gateway make REST calls on the service endpoints, instead of the `external` endpoints. In the steps documented in this topic, replace `mgmtPlatformEndpointCASecret` with `mgmtPlatformEndpointSvcCASecret`, and `mgmtConsumerEndpointCASecret` with `mgmtConsumerEndpointSvcCASecret`. For `secretName`, the default for the service endpoints is `mgmt-ca` or `<apic instance name>-mgmt-ca`.

Procedure

1. Update the portal CR.
   a. Edit the portal CR

```
oc edit ptl
```

   Note: If you are using the OpenShift top-level CR deployment, edit your `APIConnectCluster` CR instead. Updates should be made in the `spec.portal` section.
   b. Set `spec.mgmtPlatformEndpointCASecret.secretName` and `spec.mgmtConsumerEndpointCASecret.secretName` to the name of the CA secret.

```
spec:
...
  mgmtPlatformEndpointCASecret:
    secretName: <instance name>-ingress-ca
  mgmtConsumerEndpointCASecret:
    secretName: <instance name>-ingress-ca
```

2. Update the gateway CR.
   a. Edit the gateway CR

```
oc edit gw
```

Note: If you are using the OpenShift top-level CR deployment, edit your `APIConnectCluster` CR instead. Updates should be made in the `spec.portal` section.

b. Set `spec.mgmtPlatformEndpointCASecret.secretName` to the name of the CA secret.

```
spec:
...
  mgmtPlatformEndpointCASecret:
    secretName: <instance name>-ingress-ca
```

Enable JWT security and disable mTLS between subsystems

Postinstallation steps to enable JWT security and disable mTLS between subsystems.

About this task

JWT security is an alternative to using mTLS to secure inter-subsystem communication. For more information on JWT security and when to use it, see: Enable JWT security instead of mTLS.

If you disable mTLS then you must enable JWT.
Note: It is not possible to use JWT on the V5 compatible gateway to analytics message flow. This flow is secured by mTLS, which cannot be disabled.

Procedure

1. Describe the management CR to get the JWKS URL:

```
oc describe mgmt

Status:
  Endpoints:
    - name: jwksUrl
      secretName: api-endpoint
      type: API
      uri: https://api.apic.acme.com/api/cloud/oauth2/certs
```

2. For each portal, gateway, and analytics subsystem where you want to use JWT security, update the CR corresponding to that subsystem, and set `spec.mtlsValidateClient` to `false`, and `spec.jwksUrl` to the JWKS URL you identified in step 1.

```
spec:
...
  mtlsValidateClient: false
  jwksUrl: <JWKS URL>
```

Note: If you are using the OpenShift top-level CR deployment, edit your `APIConnectCluster` CR instead. Updates should be made in appropriate the `spec.<subsystem name>` section.

3. Enable JWT on the gateway to analytics communications flow. Enable the Use JWT switch for the registered gateway in the Topology page of the Cloud Manager UI.

Troubleshooting installation on OpenShift

Review the following known issues and troubleshooting tips if you encounter a problem while installing API Connect on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Failed `integration-ibm-cloud-native-postgresql` `CatalogSource` on ROKS 4.14 and OpenShift Container Platform 4.15

The API Connect operator creates the EDB catalog source in the same namespace as the API Connect operator.

The EDB catalog source reports a failed state and shows the following status message:

```
Status:
  Message:  couldn't ensure registry server - error ensuring pod: : error creating new pod: integration-ibm-cloud-native-
postgresql-: pods "integration-  ibm-cloud-native-postgresql-hnjbn" is forbidden: violates PodSecurity "restricted:v1.24":
allowPrivilegeEscalation != false (container "registry-server"   must set securityContext.allowPrivilegeEscalation=false),
unrestricted capabilities (container "registry-server" must set   securityContext.capabilities.drop=["ALL"]), runAsNonRoot !=
true (pod or container "registry-server" must set securityContext.runAsNonRoot=true),   seccompProfile (pod or container
"registry-server" must set securityContext.seccompProfile.type to "RuntimeDefault" or "Localhost")
  Reason:   RegistryServerError
```

The problem occurs when the namespace is set to enforce the restricted pod security admission policy with the `pod-security.kubernetes.io/enforce: restricted` label.

ROKS 4.14 and some OpenShift Container Platform versions such as 4.15 have `enforce` set to `restricted`.

To workaround this problem, update the `integration-ibm-cloud-native-postgresql` `CatalogSource` to use the restricted security context constraint:

```
oc patch CatalogSource integration-ibm-cloud-native-postgresql --type merge --patch '{"spec":{"grpcPodConfig":
{"securityContextConfig":"restricted"}}}'
```

One or more pods in `CrashLoopBackoff` or `Error` state, and report a certificate error in the logs

In rare cases, cert-manager might detect a certificate in a bad state right after it has been issued, and then re-issues the certificate. If a CA certificate has been issued twice, the certificate that was signed by the previously issued CA will be left stale and can't be validated by the newly issued CA. In this scenario, one of the following messages displays in the log:

- `javax.net.ssl.SSLHandshakeException: Received fatal alert: certificate_unknown`
- `Error: unable to verify the first certificate`
- `ERROR: openssl verify failed to verify the Portal CA tls.crt, ca.crt chain signed the Portal Server tls.crt cert`

Resolve the problem by completing the following steps:

1. Use `apicops` (v10 version 0.10.57+ required) to validate the certificates in the system:

   ```
   apicops upgrade:stale-certs -n <namespace>
   ```

2. If any certificate that is managed by cert-manager fails the validation, delete the stale certificate secret:

   ```
   oc delete secret <stale-secret> -n <namespace>
   ```

   Cert-manager automatically generates a new certificate to replace the one you deleted.

3. Use `apicops` to make sure all certificates can be verified successfully:

   ```
   apicops upgrade:stale-certs -n <namespace>
   ```

You see the `denied: insufficient scope` error during an air-gapped deployment

Problem: You encounter the `denied: insufficient scope` message while mirroring images during an air-gapped installation or upgrade.

Reason: This error occurs when a problem is encountered with the entitlement key that is used for obtaining images.

Solution: Obtain a new entitlement key by completing the following steps:

1. Log in to the IBM Container Library.
2. In the Container software library, select Get entitlement key.
3. After the Access your container software heading, click Copy key.
4. Copy the key to a safe location.

Apiconnect operator pod fails

Problem: During installation (or upgrade), the `apiconnect` operator fails with the following message:

```
panic: unable to build API support: unable to get Group and Resources: unable to retrieve the complete list of server APIs:
packages.operators.coreos.com/v1: the server is currently unable to handle the request

goroutine 1 [running]:
github.ibm.com/velox/apiconnect-operator/operator-utils/v2/apiversions.GetAPISupport(0x0)
        operator-utils/v2/apiversions/api-versions.go:89 +0x1e5
main.main()
        ibm-apiconnect/cmd/manager/main.go:188 +0x4ee
```

Additional symptoms:

- Apiconnect operator is in crash loopback status
- Kube `apiserver` pods log the following information:

  ```
  E1122 18:02:07.853093 18 available_controller.go:437] v1.packages.operators.coreos.com failed with:
   failing or missing response from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1:
   bad status from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1: 401
  ```

- The IP logged here belongs to the *package server* pod present in the `openshift-operator-lifecycle-manager` namespace
- Package server pods log the following error message: `/apis/packages.operators.coreos.com/v1 API call is being rejected with 401 issue`.

  ```
  E1122 18:10:25.614179 1 authentication.go:53] Unable to authenticate the request due to an error: x509:
  certificate signed by unknown authority I1122 18:10:25.614224 1 httplog.go:90]
  verb="GET" URI="/apis/packages.operators.coreos.com/v1" latency=161.243µs resp=401
  UserAgent="Go-http-client/2.0" srcIP="10.128.0.1:41370":
  ```

- The problem is intermittent

Solution:

- If you find the exact symptoms as described, the solution is to delete package server pods in the `openshift-operator-lifecycle-manager` namespace.
- New package server pods log the `200 Success` message for the same API call.

Disabling the Portal web endpoint check

When you create or register a Developer Portal service, the Portal subsystem checks that the Portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-www` pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the Portal web endpoint check so that the Developer Portal service can be created successfully.
To disable the endpoint check, complete the following update:

On Kubernetes, OpenShift, and IBM® Cloud Pak for Integration
: Add the following section to the Portal custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

Upgrading API Connect

Upgrade API Connect on Kubernetes and OpenShift platforms to a newer version.

Upgrading your API Connect deployment consists of three phases:

1. Upgrade planning. Decide on your upgrade path based on your platform and current version. It might be necessary to upgrade your container environment before you can upgrade API Connect.

   Review any feature changes in the new API Connect version that might impact how you use API Connect and plan for such changes.

   Upgrade planning should be started as early as possible to identify any issues that might influence when you are able to upgrade, and any actions to take before upgrade.

2. Upgrade preparation. Run pre-upgrade checks on your current deployment, download the new version of API Connect from Fix Central, backup your current deployment. Upgrade your container platform if required.

   Upgrade preparation can be done at any time, and it is worth doing early to identify and fix any potential problems before your upgrade window. If you do complete the upgrade preparation early, repeat the pre-upgrade checks just before your upgrade window to check for any new problems.

3. Upgrade procedure. Updating your API Connect operator and operands to the new version. Upgrading cert-manager might also be necessary.

   The upgrade process should be started only when all upgrade planning and preparation are completed. Interrupting and rolling back API Connect upgrades is not possible. Disaster recovery procedures must be followed to restore API Connect to the old version if problems are encountered during upgrade.

The upgrade planning, preparation, and execution steps are different for each deployment type. Select from the following sections:

- **Upgrading on Kubernetes**
  Upgrade API Connect on Kubernetes distributions.
- **Upgrading on OpenShift and Cloud Pak for Integration**
  You can upgrade API Connect in an OpenShift environment and as part of IBM Cloud Pak for Integration.
- **Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.7 or later**
  How to upgrade an API Connect V10.0.7 (or later) two data center disaster recovery (DR) deployment on Kubernetes and OpenShift.
- **Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.5**
  How to upgrade a two data center disaster recovery deployment to V10.0.8 from V10.0.5 on Kubernetes and OpenShift.
- **Upgrading a 2DCDR deployment on Cloud Pak for Integration from V10.0.7 or later**
  How to upgrade from an API Connect V10.0.7 (or later) two data center disaster recovery (DR) deployment on Cloud Pak for Integration.
- **Upgrading a 2DCDR deployment on Cloud Pak for Integration from V10.0.5**
  How to upgrade from an API Connect V10.0.5 two data center disaster recovery (DR) deployment on Cloud Pak for Integration.

Upgrading on Kubernetes

Upgrade API Connect on Kubernetes distributions.

- **Planning your API Connect upgrade on Kubernetes**
  Review the supported versions, requirements, and limitations for upgrading API Connect on Kubernetes.
- **Pre-upgrade preparation and checks on Kubernetes**
  Prepare your Kubernetes environment and API Connect deployment for upgrade.
- **Upgrading DataPower Operator and Operand independently of the APIC**
  API Connect and DataPower each have their own Operator, which manages their respective products. The Operand is the actual product that users interact with. Before deploying an Operand, its corresponding Operator must be installed at a specific version. While Operators and Operands can have different versions, each Operator supports a specific range of Operand versions. This separation allows customers to upgrade the Operator and Operand independently, reducing upgrade times. The primary use case is that customers want the flexibility to upgrade API Connect (management plane) and DataPower (data plane) separately. This allows them to either minimize the upgrade window or apply fixes to one component without affecting the other. When DataPower is deployed through API Connect in Kubernetes, API Connect strictly controls the versions of both the DataPower Operator and Operand, ensuring that management and data plane upgrades occur simultaneously. In OpenShift Container Platform and Cloud Pak for Integration, API Connect still handles Operator installation, but customers can change the Operator version without relying on Helm. The Operand upgrade process remains the same across Kubernetes, OpenShift Container Platform, and Cloud Pak for Integration.

- **Upgrading API Connect on Kubernetes**
  Upgrade your API Connect subsystems to a newer version on Kubernetes.
- **Troubleshooting upgrades on Kubernetes**
  Review the following troubleshooting guidance if you encounter a problem during an API Connect on Kubernetes.

Planning your API Connect upgrade on Kubernetes

Review the supported versions, requirements, and limitations for upgrading API Connect on Kubernetes.

Supported upgrade paths

Table 1 lists the supported upgrade paths for API Connect and explains whether a direct upgrade is supported or an interim upgrade is required.

Table 1. Supported upgrade paths on Kubernetes

Upgrade from:	How to upgrade to 10.0.8.2-ifix1
• 10.0.8.1 • 10.0.8.0 • 10.0.5.6 • 10.0.5.7 • 10.0.5.8	Note: Before upgrading to APIC v10.0.8.2-ifix1, you must run the `apicops pre-upgrade` command to check for: • Encryption-related issues • Invalid gateway-extensions Complete the procedure in Upgrading API Connect on Kubernetes.
10.0.6.0	Complete two upgrades, making sure to perform the additional steps to preserve and re-create your SFTP backup configuration: 1. Upgrade to version 10.0.7.0 as explained in Upgrading on Kubernetes in the API Connect 10.0.7.0 documentation. If you used SFTP backups for the Management subsystem in 10.0.6.0, you must temporarily remove the SFTP backup configuration before running the upgrade to 10.0.7.0: a. Edit the Management subsystem CR, delete the `databaseBackup` section, and save it so you can restore it later. b. Add the following annotation into the Management CR: `apiconnect-operator/backups-not-configured: "true"` 2. Upgrade to the current release by completing the procedures in Upgrading API Connect on Kubernetes. 3. Restore your SFTP backup configuration in the new version of API Connect: a. Edit the Management subsystem CR, and add the preserved `databaseBackup` section. b. Delete the `apiconnect-operator/backups-not-configured: "true"` annotation.
10.0.5.3 or earlier	Complete two upgrades: 1. Upgrade to version 10.0.5.4 or later as explained in Upgrading on Kubernetes in the API Connect 10.0.5.x documentation. 2. Upgrade to the current release by completing the procedures in Upgrading API Connect on Kubernetes.
10.0.5.4 or 10.0.5.5	Complete the procedure in Upgrading API Connect on Kubernetes. Note: If you are on version 10.0.5.4 or 10.0.5.5, upgrading to version 10.0.8.2-ifix1 requires updating to version 10.0.5.8 first.

Supported DataPower Gateway versions

You can use any combination of API Connect 10.0.8.x with DataPower 10.6.0.y.

Before you upgrade, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. When you find the information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

Supported versions of Kubernetes

Following table provides a quick reference of the supported Kubernetes versions for each API Connect release:

Table 2. API Connect and Kubernetes (K8S) compatibility matrix

API Connect version	K8S 1.24	K8S 1.25	K8S 1.26	K8S 1.27	K8S 1.28	K8S 1.29	K8S 1.30	K8S 1.31	K8S 1.32
10.0.5.4	✓	✓	✓	✓					
10.0.5.5			✓	✓	✓				
10.0.5.6				✓	✓	✓			
10.0.5.7				✓	✓	✓			
10.0.5.8					✓	✓	✓		
10.0.6.0	✓	✓	✓	✓					
10.0.7.0			✓	✓	✓				
10.0.8.0					✓	✓	✓		
10.0.8.1						✓	✓	✓	
10.0.8.2-ifix1							✓	✓	✓

When you upgrade API Connect, both your current deployment and your target release must support the same version of Kubernetes. After the API Connect upgrade, you can update Kubernetes to the highest version supported by the new release of API Connect.

It is possible that you must upgrade both Kubernetes and API Connect more than once to complete the process. For example, suppose that your current deployment is running API Connect 10.0.5.4 on Kubernetes v1.24 and you want to upgrade to API Connect 10.0.8.0. The highest version of Kubernetes that API Connect 10.0.5.4

supports is v1.26, and v1.28 is the lowest version of Kubernetes that API Connect10.0.8.0 supports.

In this scenario, you must make multiple upgrades of both Kubernetes and API Connect to reach the target versions; for example:

1. On your API Connect 10.0.5.4 deployment, upgrade Kubernetes from v1.24 to v1.25 to v1.26 and then to v1.27. (all interim upgrades are required).
2. Upgrade API Connect to 10.0.7.0 on Kubernetes v1.27.
3. Upgrade Kubernetes from v1.27 to v1.28.
4. Upgrade API Connect to 10.0.8.0 on Kubernetes v1.28.
5. Optionally upgrade Kubernetes from v1.28 to v1.29 and then to v1.30 to reach the highest supported version of Kubernetes in API Connect 10.0.8.0.

Important upgrade considerations

Carefully review the following items, to plan and prepare for your upgrade.

Analytics backup changes
: In V10.0.8, the analytics database backup functions moved from the API Connect operator to the analytics subsystem pods. This change has two implications:

  - It is not possible to restore pre-V10.0.8 analytics database backups to a V10.0.8 or later analytics subsystem.
  - During the upgrade procedure, after the API Connect operator is upgraded but before the analytics subsystems are upgraded, the analytics subsystem CR status reports

    ```
    The backup and restore functionality for the API Analytics subsystem has been moved from the IBM API Connect operator
    into the API Analytics microservices.
    This means that the v5.2-sc2 operator cannot support backup and restore on versions before 10.0.8.
    Update to 10.0.8 for scheduled backups to continue.
    ```

Extra persistent storage required for analytics local backups
: If analytics database backups are configured, then beginning with 10.0.8.0, an extra PV is required to store local backups and prepare them for transmission to your remote SFTP server or object-store.

  Before you upgrade, verify that you have an extra PV available for your analytics subsystem local backups, and decide how much space to allocate to it. To estimate storage requirements for your local backups, see Estimating storage requirements.

  The default size of the new PVC is 150Gi. You can override the size to increase it during the upgrade procedure.

Analytics `n3xc4.m16` component profile is deprecated
: The analytics `n3xc4.m16` profile is deprecated in 10.0.8.0. If you use this profile, then it is recommended to switch to the `n3xc4.m32` profile. You can switch profile either before or after upgrade to V10.0.8. For information about switching profile, see Changing deployment profiles on Kubernetes and OpenShift.

API transaction failure during the upgrade of gateway
: The gateway subsystem remains available and continues processing API calls during the upgrade of the management, portal, and analytics subsystems. However, a few API transactions might fail during the upgrade of the gateway.

  When you upgrade a cluster of gateway pods, a few API transactions might fail. During the upgrade, Kubernetes removes the pod from the load balancer configuration, deletes the pod, and then starts a new pod. The steps are repeated for each pod. Socket hang-ups occur on transactions that are in process at the time the pod is terminated.

  The number of transactions that fail depends on the rate of incoming transactions, and the length of time that is needed to complete each transaction. Typically the number of failures is a small percentage. This behavior is expected during an upgrade. If the failure level is not acceptable, schedule the upgrade during an off-hours maintenance window.

  DataPower Gateway supports long-lived connections such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when you upgrade. Workloads with long-lived connections are more vulnerable to failed API transactions during upgrading.

  You can limit the number of failed API transactions during the upgrade by using the DataPower Operator's `lifecycle` property to configure the `preStop` container lifecycle hook on the gateway pods. This approach mitigates the risk of API failures during the rolling update of the gateway StatefulSet by sleeping the pod for a span of time, allowing in-flight transactions to complete before the SIGTERM is delivered to the container. While this feature does not guarantee no in-flight API call failures, it does provide some mitigation for in-flight transactions that can complete successfully within the configured time window. For more information, see Delaying SIGTERM with preStop in the DataPower documentation.

FIPS support
: API Connect is not supported in a FIPS-enabled environment on Kubernetes.

OAuth provider resources with `api.securityDefintions`
: If you have native OAuth providers that are configured with the `api.securityDefintions` field assigned, then upgrade fails. Before upgrade, remove all `api.securityDefintions` from all native OAuth providers that you configured in the Cloud Manager and API Manager UIs:

  - Configuring a native OAuth provider in the Cloud Manager UI
  - Configuring a native OAuth provider in the API Manager UI

  Switch to the source view and delete any `securityDefintions` sections that are present.

Extra backup folder appended to management database backup path
: When you upgrade to V10.0.7.0 or later with S3 backups configured, an extra backup path folder /edb is appended to your backup path. The /edb path distinguishes new EDB backups from your previous management backups.

Extra persistent storage requirement for management subsystem
: Upgrading to V10.0.7.0 or later requires extra persistent storage space for the management subsystem. Verify that your environment has at least as much extra capacity as the capacity assigned to your existing Postgres PVC:

  ```
  kubectl get pvc -n <namespace>
  ```

  ```
  NAME                                        STATUS   VOLUME              CAPACITY   ACCESS MODES   STORAGECLASS     AGE
  ```

```
def-management-site1-postgres              Bound    local-pv-7b528204   244Gi      RWO            local-storage   125d
def-management-site1-postgres-pgbr-repo    Bound    local-pv-8d425510   244Gi      RWO            local-storage   125d
def-management-site1-postgres-wal          Bound    local-pv-ee8feb38   244Gi      RWO            local-storage   125d
```

Analytics persistent queue enablement requires extra PV. Upgrades from V10.0.5

The analytics persistent queue feature is enabled during the upgrade (if it was not already enabled). This feature requires an extra Physical Volume (PV). Before you upgrade from V10.0.5.x, ensure that your environment has an available PV.

Pre-upgrade preparation and checks on Kubernetes

Prepare your Kubernetes environment and API Connect deployment for upgrade.

This topic covers all the preparation steps you must complete before you can start the upgrade process.

Before completing the steps in this topic, review Planning your API Connect upgrade on Kubernetes to ensure that you are following a supported upgrade path and that you are aware of any API Connect feature changes that might affect your deployment.

Run the pre-upgrade health checks during your upgrade planning stage to identify any problems as early as possible. Run the checks again just before upgrade to confirm API Connect is still ready for upgrade.

Gathering and preparing upgrade files

1. Obtain the API Connect files from IBM Fix Central.
   From the IBM Fix Central site, download the following files:

   IBM API Connect *<version>* for Containers
   : Docker images for all API Connect subsystems. Filename is apiconnect-image-tool_*<version>*.

   IBM API Connect *<version>* Operator Release Files for Containers
   : Kubernetes operators and API Connect Custom Resource (CR) templates. Filename is apiconnect-operator-release-files_*<version>*.

   IBM API Connect *<version>* Security Signature Bundle File
   : Signature files for verifying the integrity of your downloads.
   Filename is signatures_*<version>*.

   IBM API Connect *<version>* Toolkit for *<operating_system>*
   : Toolkit command-line utility. Packaged as a stand-alone file, or with API Designer:
   - IBM® API Connect *<version>* Toolkit for *<operating_system>*
   - IBM® API Connect *<version>* Toolkit Designer for *<operating_system>*

   Filename is toolkit-...*<operating system>*_*<version>*.
   Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI as explained in Installing the toolkit.

   IBM API Connect *<version>* Local Test Environment
   : Optional test environment for testing locally as explained in Testing an API with the Local Test Environment.
   Filename is apic-lte-*<operating system>*_*<version>*.

2. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
3. Upload the image files to your docker registry.
   a. Load the image-tool image for the new API Connect version into your local Docker registry:

   ```
   docker load < apiconnect-image-tool-<version>.tar.gz
   ```

   Ensure that the registry has sufficient disk space for the files.

   b. If your Docker registry requires repositories to be created before images can be pushed, create the repositories for each of the images that the image tool lists. If your Docker registry does not require creation of repositories, skip to step 3.c.
      i. Run the following command to get a list of the images from image-tool:

      ```
      docker run --rm apiconnect-image-tool-<version> version --images
      ```

      ii. From the output of each entry of the form `<image-name>:<image-tag>`, use your Docker registry repository create command to create a repository for `<image-name>`.
      For example, in AWS ECR the command for each `<image-name>` is:

      ```
      aws ecr create-repository --repository-name <image-name>
      ```

   c. Upload the image:
   - If you do not need to authenticate with the docker registry, use:

     ```
     docker run --rm apiconnect-image-tool-<version> upload <registry-url>
     ```

   - If you need to authenticate and your docker registry accepts the username and password arguments, use:

     ```
     docker run --rm apiconnect-image-tool-<version> upload <registry-url> --username <username> --password
     <password>
     ```

   - Otherwise, if you need the image-tool to use your local Docker credentials (for example, with IBM Container Registry), first authenticate with your Docker registry, and then upload images with the command:

     ```
     docker run --rm -v ~/.docker:/root/.docker --user 0 apiconnect-image-tool-<version> upload <registry-url>
     ```

     Review the following installation notes for your environment:

     - Alternative Docker command for macOS if Docker is configured to use osxkeychain
     - Docker authentication notes

- Providing a certificate for verification, or disabling TLS verification

If necessary, you can populate a remote container registry with repositories. Then you can push the images from the local registry to the remote registry.

4. Extract the `IBM API Connect <version> Operator Release Files for Containers` that you downloaded in step 1.
   Create a directory called `helper_files` and extract the contents of `helper_files.zip` from the release_files.zip into the `helper_files` directory.

5. **If upgrading from 10.0.5.x or 10.0.7.0:** If you do not use cert-manager, create a certificate for the new consumer catalog, and add it to the management CR. Beginning with version 10.0.8.0, API Connect includes the Consume Catalog feature. If you are upgrading to 10.0.8.0 or later from 10.0.5.x or 10.0.7.0 and do not use cert-manager, you must provide a certificate for the Consumer Catalog during the upgrade.

   a. Create a certificate.
   b. Update the management CR and add the following endpoint for the Consumer Catalog with the secret name for the new certificate:

```
consumerCatalogEndpoint:
  hosts:
  - name: consumer-catalog.<domain>
    secretName: <custom-management-consumer-catalog-endpoint>
```

Pre-upgrade health-checks

1. Check that the API Connect operator and subsystems are all running.
   To verify the health of each subsystem, run the following commands:

```
kubectl get ManagementCluster -n <management namespace>
kubectl get GatewayCluster -n <gateway namespace>
kubectl get PortalCluster -n <portal namespace>
kubectl get AnalyticsCluster -n <analyticsnamespace>
```

   Confirm that all pods are `READY`, for example:

```
kubectl get PortalCluster -n apic
NAME      READY   STATUS    VERSION    RECONCILED VERSION   AGE
portal    3/3     Running   version    version-95    57m
```

2. **If upgrading from 10.0.5.x:** Verify that the management subsystem's `pgcluster` is working correctly:
   a. Get the name of the `pgcluster`:

```
kubectl get pgcluster -n <management namespace>
```

   The response displays the name of the postgres cluster that is running in the specified namespace.

   b. Check the status of the `pgcluster`:

```
kubectl get pgcluster <pgcluster_name> -n <APIC_namespace> -o yaml | grep status -A 2 | tail -n3
```

   A successful response looks like the following example, where the state is `Initialized`:

```
status:
    message: Cluster has been initialized
    state: pgcluster Initialized
```

   Important: If the `pgcluster` returns any other state, then do not proceed with the upgrade.
   - If backup or restore jobs are running, wait until they complete and then check the status again. Do not proceed with the upgrade until the status is `Initialized`.
   - If all background jobs are complete but the `pgcluster` does not return `state: pgcluster Initialized`, then contact IBM Support for assistance.

3. Run the pre-upgrade health check:
   Note: If you have a 2DCDR deployment, run this check only on the active management subsystem.
   a. Verify that the `apicops` utility is installed and that you have the latest version by running the following command:

```
apicops --version
```

   For more information about the `apicops` utility, see The API Connect operations tool: apicops.

   b. Run the following command to set the KUBECONFIG environment variable.

```
export KUBECONFIG=</path/to/kubeconfig>
```

   c. Run the **apicops pre-upgrade-check** check for the management, portal, and analytics subsystems:
   - Management subsystem:

```
apicops system:pre-upgrade-check management -n <namespace>
```

     Before upgrading, run the following command to check for encryption issues and invalid gateway extensions:

     For a full check (requires admin password to verify topology):

```
apicops preupgrade -n <namespace>
```

     To skip topology verification (no admin password needed):

```
apicops preupgrade --no-topology -n <namespace>
```

   - Portal subsystem:

```
apicops system:pre-upgrade-check portal -n <namespace>
```

   - Analytics subsystem:

```
apicops system:pre-upgrade-check analytics -n <namespace>
```

If your API Connect deployment is working correctly, the output shows no error messages.

If the pre-upgrade check returns any errors, then collect the output and open a support case.

Additional pre-upgrade checks and operations

Extra checks and operations to review and complete before you start the upgrade.

1. **Upgrades from V10.0.5.x:** If the analytics persistent queue is not enabled, verify that you have an extra Physical Volume available.
   For more information about this requirement, see Analytics persistent queue enablement requires extra PV.
2. If analytics database backups are configured, or you want to enable them in future, then ensure that you have an extra Physical Volume available for the local backup storage. The default size is 150Gi. You can override the size during the upgrade procedure.
3. If you used any microservice image overrides in any of your API Connect subsystem CRs, remove the image overrides before upgrade.

Backup your API Connect deployment

If upgrade fails, rollback is not possible. Before upgrade complete the disaster recovery preparation for all your subsystems.

For instructions on backing up and disaster recovery preparation, see the following topics:

- v10.0.7.0: Backing up, restoring, and disaster recovery
- v10.0.5.4 or later: Backups on Kubernetes, Disaster recovery.

Upgrading DataPower Operator and Operand independently of the APIC

API Connect and DataPower each have their own Operator, which manages their respective products. The Operand is the actual product that users interact with. Before deploying an Operand, its corresponding Operator must be installed at a specific version. While Operators and Operands can have different versions, each Operator supports a specific range of Operand versions. This separation allows customers to upgrade the Operator and Operand independently, reducing upgrade times. The primary use case is that customers want the flexibility to upgrade API Connect (management plane) and DataPower (data plane) separately. This allows them to either minimize the upgrade window or apply fixes to one component without affecting the other. When DataPower is deployed through API Connect in Kubernetes, API Connect strictly controls the versions of both the DataPower Operator and Operand, ensuring that management and data plane upgrades occur simultaneously. In OpenShift Container Platform and Cloud Pak for Integration, API Connect still handles Operator installation, but customers can change the Operator version without relying on Helm. The Operand upgrade process remains the same across Kubernetes, OpenShift Container Platform, and Cloud Pak for Integration.

Operand upgrade

You can upgrade the DP operand while APIC controls the DP operator version, see Overriding the default DataPower image, version, and license. The operand version that you specify must be compatible with the installed DataPower Operator version. For compatibility information, see DP Operator and Operand Compatibility matrix. If operand is not compatible, you must update the DataPower Operator.

You can update the GatewayCluster CR to override the image, version, and license information for the Gateway subsystem.

The DataPower operand images are pushed to the IBM Entitled Registry. If the image is to be pulled from the IBM Entitled Registry, an Entitlement Key must be used as an Image Pull Secret. You can obtain an Entitlement Key from My IBM, see Entitlement keys.

1. Create the Secret using your own Entitlement Key in the same namespace as the GatewayCluster subsystem.

```
oc create secret docker-registry \
  ibm-entitlement-key \
  --docker-username=cp \
  --docker-password=<entitlement-key> \
  --docker-server=cp.icr.io
```

2. Specify your secret in GatewayCluster CR under `imagePullSecrets` property to pull the operand images from the registry.

```
apiVersion: gateway.apiconnect.ibm.com/v1beta1
kind: GatewayCluster
metadata:
  name: api-gateway
spec:
  dataPowerOverride:
     version: 10.5.0.3
     license: X-XXXX-XXXXXX
  imagePullSecrets:
  - ibm-entitlement-key
```

3. When a custom registry is used, or if you want to a specific image (for urgent/hot fixes), it is important to specify the image field in the override. This scenario is not typical.

```
apiVersion: gateway.apiconnect.ibm.com/v1beta1
kind: GatewayCluster
metadata:
  name: api-gateway
spec:
  dataPowerOverride:
     image: customregistry.com/custom-image-datapower:10.5.0.3
     version: 10.5.0.3
     license: X-XXXX-XXXXXX
```

```
  imagePullSecrets:
  - ibm-entitlement-key
```

Operator upgrade

If you want greater flexibility in what DP operand version is installed, as well as plan to install DP operator/operand at different times than APIC, it is recommended to do the following steps so that you can control version of operator rather than APIC deciding operator version. The following allows you to install DP operator at different times compared to APIC operator.

Make sure that the version of the DataPower Operator you're installing is compatible with the APIC version. You can find the compatibility information in the following matrix:

API Connect Operator version	API Connect Operand version	DataPower minimum Operator version	DataPower supported Operand version
5.3.0	10.0.8.1	1.11.2	DP Operator and Operand Compatibility matrix

If you previously used the Helm Chart to install the DataPower Operator, then to upgrade Operator, see Upgrading with Helm.

If you want to install the DataPower by using Helm chart after the Operator installation was done through the APIC shipped yaml files, uninstall the DataPower operator by running the following command:

```
kubectl delete -f ibm-datapower.yaml -n <namespace>
```

Install the DataPower Operator by using the Helm chart, see Installation with Helm.

Use new CRD during upgrade

If you use Helm chart to upgrade DP operator, use different file to apply new APIC CRDs during APIC upgrades instead of using file to apply combined APIC and DP operator CRDs. See Upgrading API Connect on Kubernetes.

If you upgraded the DataPower Operator by using the Helm Chart independently of the APIC, run the following command to apply the new CRDs from the extracted version (contains only APIC CRDs):

```
kubectl apply -f ibm-apiconnect-only-crds.yaml
```

Otherwise, run the following command to apply the new CRDs from the extracted version (contains both APIC and DP CRDs):

```
kubectl apply -f ibm-apiconnect-crds.yaml
```

Upgrading API Connect on Kubernetes

Upgrade your API Connect subsystems to a newer version on Kubernetes.

Before you begin

Review Planning your API Connect upgrade on Kubernetes and complete the Pre-upgrade preparation and checks on Kubernetes.

About this task

- To ensure operator compatibility, upgrade the API Connect management subsystem first and the gateway subsystem second. This requirement applies to all upgrade scenarios.
- The gateway subsystem remains available during the upgrade of the management, portal, and analytics subsystems.

Notes:

- If any subsystem database backups are running or are scheduled to run within a few hours, do not start the upgrade process.
- Do not perform maintenance tasks such as updating certificates, restoring subsystem databases from backup, or triggering subsystem database backups at any time while you are upgrading API Connect.

Procedure

1. If you did not run the pre-upgrade health checks recently, run them now.
2. If you have a two data center disaster recovery deployment, then upgrade the warm-standby data center first.
   See the special steps for 2DCDR upgrades:
   - Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.5
   - Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.7 or later
3. Apply the API Connect CRDs that you downloaded and extracted in the pre-upgrade steps:

   ```
   kubectl apply --server-side --force-conflicts -f ibm-apiconnect-crds.yaml
   ```

4. Apply the new DataPower Operator YAML into the namespace where the DataPower operator is running.
   a. Edit the `ibm-datapower.yaml` file and set the following properties:the `namespace` property to the namespace where you deployed the operator.
      - Set all instances of the `namespace` property to the namespace where you deployed the operator.
      - Set the `containers.image` property to the location of the `datapower-operator` image, either uploaded to your own registry or pulled from a public registry.

   b. Run the following command:

      ```
      kubectl -n <namespace> apply -f ibm-datapower.yaml
      ```

      The gateway CR goes to `Pending` state when the operator is updated, and then changes to `Running` after installation of the API Connect operator in the next step.

Troubleshooting: If your DataPower operator pod fails to start, see Troubleshooting upgrade.

5. Upgrade cert-manager to version 1.16.3.
   a. Run the following command to back up the existing certificates and issuers to a file called backup.yaml:

   ```
   kubectl get --all-namespaces -oyaml issuer,clusterissuer,cert,secret > backup.yaml
   ```

   b. Run the following command to verify the version of cert-manager that you are upgrading:
      - API Connect 10.0.5.4: verify that you are upgrading cert-manager 1.9.1:

      ```
      kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
      v1.9.1
      ```

      - API Connect 10.0.5.5 or 10.0.7.0: verify that you are upgrading cert-manager 1.11.5:

      ```
      kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
      v1.11.5
      ```

      - API Connect 10.0.5.6: verify that you are upgrading cert-manager 1.12.7:

      ```
      kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
      v1.12.7
      ```

      - API Connect 10.0.5.7: verify that you are upgrading cert-manager 1.12.9:

      ```
      kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
      v1.12.9
      ```

      - API Connect 10.0.5.8: no upgrade needed.
      - API Connect 10.0.8.0: verify that you are upgrading cert-manager 1.12.10:

      ```
      kubectl get crds certificates.cert-manager.io -o jsonpath='{.metadata.labels.app\.kubernetes\.io\/version}'
      v1.12.10
      ```

   c. Run the following command to upgrade cert-manager to version 1.16.3:

   ```
   kubectl apply -f helper_files/cert-manager-1.16.3.yaml
   ```

6. If you generated your internal certificates with the custom-certs-internal.yaml file when you installed API Connect (following these steps Generating custom certificates using cert-manager), then apply the new custom-certs-internal.yaml file from your target release files and renew `db-server-certificate`.
   Note: If you are not sure if API Connect was installed with custom-certs-internal.yaml, then check the follow these steps to confirm:
   a. Check whether the management CR has a `customCertificates` section:

   ```
   kubectl -n <management namespace> get mgmt -o yaml | grep customCertificates
   ```

   If the management CR does not have this section, then custom-certs-internal.yaml was not used. If it does have this section, then continue to the next check.

   b. Check the issuer of the `management-server` certificate:

   ```
   kubectl -n <management namespace> describe secret management-server | grep issuer-name
   ```

   If the command returns:

   ```
    cert-manager.io/issuer-name: ingress-issuer
   ```

   then custom-certs-internal.yaml was used.
   a. Edit the new custom-certs-internal.yaml file. Replace all instances of `<namespace>` and `<site_name>` with the values from the original custom-certs-internal.yaml file that you used during installation.
   b. Apply the new custom-certs-internal.yaml file.

   ```
   kubectl apply -f helper_files/custom-certs-internal.yaml
   ```

   c. Renew `db-server-certificate`.

   ```
   kubectl -n <management namespace> delete secret db-server-certificate
   ```

7. Clean up the webhook configuration before you deploy the newer API Connect operator:
   a. Run the following command to get the webhook configuration:

   ```
   kubectl get mutatingwebhookconfiguration,validatingwebhookconfiguration | grep ibm-apiconnect
   ```

   b. Use the `kubectl delete` command to delete the webhook configuration; for example:

   ```
   kubectl delete mutatingwebhookconfiguration ibm-apiconnect-mutating-webhook-configuration
   kubectl delete validatingwebhookconfiguration ibm-apiconnect-validating-webhook-configuration
   ```

8. Apply the new API Connect operator YAML into the namespace where the API Connect operator is running.
   - For a single-namespace deployment:
     - If the operator is not running in the `default` namespace, edit the `ibm-apiconnect.yaml` and replace all references to `default` with the name of the namespace where you deployed API Connect.
       Note: If you are using Operator Lifecycle Manager (OLM), then skip this step.
     - Edit `ibm-apiconnect.yaml` file and replace the value of each `image` property with the location of the `apiconnect` operator images (from the `ibm-apiconnect` container and the `ibm-apiconnect-init` container), either uploaded to your own registry or pulled from a public registry.
     - Run the following command:

     ```
     kubectl -n <namespace> apply -f ibm-apiconnect.yaml
     ```

   - For a multi-namespace deployment:
     - Edit the `ibm-apiconnect-distributed.yaml` file and replace each occurrence of `$OPERATOR_NAMESPACE` with the namespace for the deployment.

- Also in `ibm-apiconnect-distributed.yaml`, set the values of the `containers.image` properties. Replace the placeholder values `REPLACE-DOCKER-REGISTRY` with the docker registry host location of the API Connect operator image (either uploaded to own registry or pulled from public registry).
- Install `ibm-apiconnect-distributed.yaml` with the following command:

  ```
  kubectl apply -f ibm-apiconnect-distributed.yaml
  ```

9. Verify that the `ibm-datapower-operator` and the `ibm-apiconnect` operators are restarted.
10. Ensure that the `apiconnect` operator re-created the necessary microservices:

    ```
    kubectl get apic -n <namespace>
    ```

    Do not proceed to upgrade the API Connect subsytems until the operator upgrade is complete.

    Note: If analytics backups are configured, then after the API Connect operator is upgraded, the analytics CR reports a status of `Blocked` until the analytics subsystem is upgraded to V10.0.8. With top-level CR deployments, the `apiconnectcluster` CR reports `Pending` until the analytics CR is no longer `Blocked`. For more information, see Analytics backup changes.
11. Upgrade the API Connect subsystems:
    a. Upgrading the management subsystem on Kubernetes
    b. Upgrading the gateway subsystem on Kubernetes
    c. Upgrading the portal subsystem on Kubernetes
    d. Upgrading the analytics subsystem on Kubernetes
12. Verify that the upgraded subsystems report as `Running` and the `RECONCILED VERSION` displays the new version of API Connect.
    Run the following command:

    ```
    kubectl get apic --all-namespaces
    ```

    Example response:

    ```
    NAME                                                READY   STATUS    VERSION              RECONCILED VERSION      AGE
    analyticscluster.analytics.apiconnect.ibm.com/analytics      8/8     Running   10.0.8.2-ifix1   10.0.8.2-ifix1-1074   121m

    NAME                                        PHASE     READY   SUMMARY                            VERSION    AGE
    datapowerservice.datapower.ibm.com/gw1   Running   True    StatefulSet replicas ready: 1/1   10.0.8.2-ifix1   100m

    NAME                                        PHASE     LAST EVENT   WORK PENDING   WORK IN-PROGRESS   AGE
    datapowermonitor.datapower.ibm.com/gw1   Running                false          false              100m

    NAME                                          READY   STATUS    VERSION              RECONCILED VERSION      AGE
    gatewaycluster.gateway.apiconnect.ibm.com/gw1   2/2     Running   10.0.8.2-ifix1   10.0.8.2-ifix1-1074   100m

    NAME                                             READY   STATUS    VERSION              RECONCILED VERSION      AGE
    managementcluster.management.apiconnect.ibm.com/m1   16/16   Running   10.0.8.2-ifix1   110.0.8.2-ifix1-1074   162m

    NAME                                          READY   STATUS    VERSION              RECONCILED VERSION      AGE
    portalcluster.portal.apiconnect.ibm.com/portal   3/3     Running   10.0.8.2-ifix1   10.0.8.2-ifix1-1074   139m
    ```

    Important: If you need to restart the deployment, wait until all portal sites complete the upgrade.
    After the portal subsystem upgrade is complete, each portal site is upgraded. You can monitor the site upgrade progress from the `MESSAGE` column in the `oc get ptl` output. You can still use the portal while sites are upgrading, although a maintenance page is shown for any sites that are being upgraded. When the site upgrades are complete, the `oc get ptl` output shows how many sites the portal is serving:

    ```
    NAME      READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE              AGE
    portal    3/3     Running   <version>        <version>            Serving 2 sites      22h
    ```

    On two data center disaster recovery deployments, the sites are not upgraded until both data centers are upgraded.

13. Optional: **If upgrading from 10.0.5.x or 10.0.7.0:** Provide a custom endpoint for the Consumer Catalog.
    Skip this step if you are upgrading from 10.0.8.0 or later.

    Beginning with version 10.0.8.0, API Connect includes the Consumer Catalog feature. If your deployment uses cert-manager, then during the upgrade from 10.0.5.x or 10.0.7.0, a new endpoint is added to the management CR for the Custom Catalog.

    The following definition is generated and automatically added to the management CR during the upgrade, using a certificate from cert-manager:

    ```
      consumerCatalogEndpoint:
        annotations:
          cert-manager.io/issuer: ingress-issuer
        hosts:
        - name: consumer-catalog.<domain>
          secretName: <name>-consumer-catalog-endpoint
    ```

    a. Make the following optional changes to the endpoint definition in the CR:
       - Change the `name` to a host name of your own choosing.
       - Specify a custom cert-manager certificate.
    b. Run the following command to save and apply the CR: `wq`
14. Optional: For the optional components API Connect Toolkit and API Connect Local Test Environment, install the latest version of each after you complete the upgrade of the subsystems.

- **Upgrading the management subsystem on Kubernetes**
  Upgrade the management subsystem to a newer version of API Connect on Kubernetes.
- **Upgrading the portal subsystem on Kubernetes**
  Upgrade the portal subsystem to a newer version of API Connect on Kubernetes.
- **Upgrading the analytics subsystem on Kubernetes**
  Upgrade the analytics subsystem to a newer version of API Connect on Kubernetes.
- **Upgrading the gateway subsystem on Kubernetes**
  Upgrade the gateway subsystem to a newer version of API Connect on Kubernetes.

Upgrading the management subsystem on Kubernetes

Upgrade the management subsystem to a newer version of API Connect on Kubernetes.

Before you begin

Review and complete all steps in:

- Planning your API Connect upgrade on Kubernetes
- Pre-upgrade preparation and checks on Kubernetes
- Upgrading API Connect on Kubernetes

About this task

Upgrade the management subsystem by updating the version property in your management CR. The API Connect operator detects this change and starts the upgrade.

Procedure

1. Update the management CR for the new version of API Connect.
   a. Run the following command to edit the management CR:

      ```
      kubectl -n <namespace> edit mgmt
      ```

   b. Update `spec.version` in the management CR to your target version:
      For example:

      ```
      version: 10.0.8.2-ifix1
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update `spec.license`.
      For example:

      ```
      license: L-DZZQ-MGVN8V
      ```

      For the list of licenses, see API Connect licenses.

   d. [This step is not applicable if you are upgrading from 10.0.8.0 or 10.0.8.1 to 10.0.8.2-ifix1] If you have a two data center disaster recovery installation, and are upgrading the warm-standby, then add the annotation:

      ```
      apiconnect-operator/dr-warm-standby-upgrade-data-deletion-confirmation: "true"
      ```

      For more information about two data center disaster recovery upgrade, see Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.5.
   e. If you are upgrading from V10.0.5 and you generated your internal certificates with the custom-certs-internal.yaml file when you installed API Connect (following these steps Generating custom certificates using cert-manager), then add the new `db-client-replication` certificate in the `customCertificates` section:

      ```
      customCertificates:
        ...
        - name: dbClientReplicator
          secretName: db-client-replication
      ```

   f. Run the following command to save and apply the CR: `wq`
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the Troubleshooting upgrades on Kubernetes.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl -n <namespace> get apic
   ```

   Example output after management subsystem upgrade:

   ```
   NAME                                                READY   STATUS    VERSION              RECONCILED VERSION      AGE
   managementcluster.management.apiconnect.ibm.com/m1   16/16   Running   <version>   <version-build>   162m

   NAME                                                                 STATUS    MESSAGE
   AGE
   managementdbupgrade.management.apiconnect.ibm.com/management-up-8c28g   Running   Upgrade is running (DB Schema/data are
   up-to-date)   13m
   ```

   If the upgrade appears to be stuck, showing the status of `Pending` for a long time, then check the management CR status for errors:

   ```
   kubectl -n <namespace> get mgmt -o yaml
   ```

   Refer to Troubleshooting upgrades on Kubernetes, for known issues.

What to do next

Upgrade your portal subsystem: Upgrading the portal subsystem on Kubernetes.

Upgrading the portal subsystem on Kubernetes

Upgrade the portal subsystem to a newer version of API Connect on Kubernetes.

Before you begin

Review and complete all steps in:

- Planning your API Connect upgrade on Kubernetes
- Pre-upgrade preparation and checks on Kubernetes
- Upgrading API Connect on Kubernetes
- Upgrading the management subsystem on Kubernetes

About this task

Upgrade the portal subsystem by updating the version property in your portal CR. The API Connect operator detects this change and starts the upgrade.

Procedure

1. Update the portal CR for the new version of API Connect.
   a. Run the following command to edit your portal CR:

      ```
      kubectl -n <namespace> edit ptl
      ```

   b. Set the `spec.version` property in the portal CR to your target version:
      For example:

      ```
      version: 10.0.8.2-ifix1
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update `spec.license`.
      For example:

      ```
      license: L-DZZQ-MGVN8V
      ```

      For the list of licenses, see API Connect licenses.

   d. Run the following command to save and apply the CR: `wq`
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl -n <namespace> get apic
   ```

   Example output after portal subsystem upgrade:

   ```
   NAME                                                READY   STATUS    VERSION     RECONCILED VERSION   MESSAGE
   AGE
   portalcluster.portal.apiconnect.ibm.com/portal      3/3     Running   <version>   <version>            Site Upgrades
   Executing:(1) Queued(5) Failed(0) Success(0)   22h
   ```

   Note: After the portal subsystem upgrade is complete, each portal site is upgraded. You can monitor the site upgrade progress from the `MESSAGE` column in the `kubectl get apic` output. You can still use the portal while sites are upgrading, although a maintenance page is shown for any sites that are being upgraded. When the site upgrades are complete, the `kubectl get apic` output shows how many sites the portal is serving:

   ```
   NAME     READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE              AGE
   portal   3/3     Running   <version>        <version>            Serving 2 sites      22h
   ```

   On two data center disaster recovery deployments, the sites are not upgraded until both data centers are upgraded.

   If the upgrade appears to be stuck, showing the status of `Pending` for a long time, then check the portal CR status for errors:

   ```
   kubectl -n <namespace> get ptl -o yaml
   ```

   Refer to Troubleshooting upgrades on Kubernetes, for known issues.

Upgrading the analytics subsystem on Kubernetes

Upgrade the analytics subsystem to a newer version of API Connect on Kubernetes.

Before you begin

Review and complete all steps in:

- Planning your API Connect upgrade on Kubernetes
- Pre-upgrade preparation and checks on Kubernetes
- Upgrading API Connect on Kubernetes
- Upgrading the management subsystem on Kubernetes

About this task

Upgrade the analytics subsystem by updating the version property in your analytics CR. The API Connect operator detects this change and starts the upgrade.

Procedure

1. Update the analytics CR for the new version of API Connect.
   a. Run the following command to edit the CR:

      ```
      kubectl -n <namespace> edit a7s
      ```

   b. Set the `spec.version` property in the analytics CR to your target version:
      For example:

      ```
      version: 10.0.8.2-ifix1
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update `spec.license`.
      For example:

      ```
      license: L-DZZQ-MGVN8V
      ```

      For the list of licenses, see API Connect licenses.

   d. Optional: Set the size of local database backup storage.
      Upgrades to V10.0.8.0: By default the new PVC that is created for the analytics subsystem's local database backups is set to 150Gi. If you want to specify a larger size, then add the following to the CR `spec` section:

      ```
        storage:
          backup:
            volumeClaimTemplate:
              storageClassName: <storage class>
              volumeSize: <size>
      ```

      where:
      - *<storage class>* is the same as used by your other analytics PVCs.
      - *<size>* is the size. For example: `500Gi`. See Estimating storage requirements.

   e. Save your changes to the CR.
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl get apic -n <namespace>
   ```

   Example output after an analytics subsystem upgrade:

   ```
   NAME                                                  READY   STATUS    VERSION              RECONCILED VERSION
   AGE
   analyticscluster.analytics.apiconnect.ibm.com/analytics   5/5     Running   <version>   <version-build>   121m
   ```

   If the upgrade appears to be stuck, showing the status of `Pending` for a long time, then check the analytics CR status for errors:

   ```
   kubectl -n <namespace> get a7s -o yaml
   ```

   Refer to Troubleshooting upgrades on Kubernetes, for known issues.

3. Update analytics profile.
   If your analytics subsystem uses the `n3xc4.m16` profile, then update the profile in your analytics CR to `n3xc4.m32`. For information about switching profiles, see Changing deployment profiles on Kubernetes and OpenShift

Upgrading the gateway subsystem on Kubernetes

Upgrade the gateway subsystem to a newer version of API Connect on Kubernetes.

Before you begin

Review and complete all steps in:

- Planning your API Connect upgrade on Kubernetes
- Pre-upgrade preparation and checks on Kubernetes
- Upgrading API Connect on Kubernetes
- Upgrading the management subsystem on Kubernetes

Note: To upgrade a high-availability cluster, ensure that you meet the following requirements:

- Gateways must be updated one at a time.
- Before you start the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
- To upgrade multiple gateways, upgrade the primary gateway last.
  Ensure that the pod with a name like `gwv6-0` or `gwv5-0` is the primary because it is the last node to be upgraded.

  To determine which gateway is running as primary, use either
  - The **show gateway-peering-status** command in the DataPower CLI. Access the CLI with:

    ```
    kubectl attach -it <gateway pod name>
    ```

- The Gateway Peering Status display in the WebGUI (in the API Connect application domain).

To move the primary to the DataPower on which you are working, you can issue the following command:

```
gateway-peering-switch-primary <peering-object-name>
```

About this task

Upgrade the analytics subsystem by updating the version property in your analytics CR. The API Connect operator detects this change and starts the upgrade.

Gateway upgrade can result in failure of some in-flight transactions, for more information see: API transactions might fail during the upgrade of gateway pods.

Procedure

1. Update the gateway CR for the new version of API Connect.
   a. Run the following command to edit the CR:

      ```
      kubectl -n <namespace> edit gw <gateway CR name>
      ```

      where *<gateway CR name>* is the name of your gateway CR. The names of your gateway CRs are shown in the output of: **kubectl get gw**.

   b. Set the **spec.version** property in the gateway CR to your target version:
      For example:

      ```
      version: 10.0.8.2-ifix1
      ```

   c. If you are upgrading to a version of API Connect that requires a new license, update **spec.license**.
      For example:

      ```
      license: L-DZZQ-MGVN8V
      ```

      For the list of licenses, see API Connect licenses.

   d. Delete any **template** or **dataPowerOverride** override sections.
      If the CR contains an override, an upgrade is not possible.

   e. Run the following command to save and apply the CR: **wq**
      When you save the updated CR, the upgrade starts automatically.

      Troubleshooting: If you see an error message when you attempt to save the CR, see the known upgrade issues.

2. Run the following command to verify that the upgrade was successful:

   ```
   kubectl get apic -n <namespace>
   ```

   Example output after a gateway subsystem upgrade:

   ```
   NAME                                          READY   STATUS    VERSION              RECONCILED VERSION      AGE
   gatewaycluster.gateway.apiconnect.ibm.com/gw1   2/2     Running   <version>  <version-build>  100m
   ```

Troubleshooting upgrades on Kubernetes

Review the following troubleshooting guidance if you encounter a problem during an API Connect on Kubernetes.

Subsystem is stuck in `Pending` state with a reason of `PreUpgradeCheckInProgress`

Before the subsystem microservices are upgraded, the operator triggers a set of pre-upgrade checks that must pass for the upgrade to proceed. If one or more of the checks fail, the subsystem status remains in **Pending** state with a reason of **PreUpgradeCheckInProgress**. Check the status condition of the subsystem CR to confirm the pre-upgrade check failed. The **status.PreUpgradeCheck** property contains a summary of the failed checks. Full logs for the checks that are carried out can be viewed in the **ConfigMap** referenced in the **status.PreUpgradeCheck** property. The pre-upgrade checks automatically retry until they successfully pass. If you are unable to rectify the problem that causes a check to fail, then open an IBM support case.

License webhook error

If you did not update the license ID in the CR, then when you save your changes, the following webhook error might display:

```
admission webhook "vmanagementcluster.kb.io" denied the request:
ManagementCluster.management.apiconnect.ibm.com "management" is invalid:
spec.license.license: Invalid value: "L-RJON-BYGHM4":
License L-RJON-BYGHM4 is invalid for the chosen version 10.0.8.2-ifix1.
Please refer license document https://ibm.biz/apiclicenses
```

To resolve the error, see API Connect licenses for the list of the available license IDs and select the appropriate license IDs for your deployment. Update the CR with the new license value as in the following example, and then save and apply your changes again.

Taskmanager error syncing management and gateway

If the gateways are not in sync with management after upgrade, check if the management subsystem **taskmanager** pods log the following error message. It starts 15 minutes after upgrade and repeats every 15 minutes for any stuck task.

```
TASK: Stale claimed task set to errored state:
```

If these errors are reported, restart all the `management-natscluster` pods, for example: `management-natscluster-1`.

```
kubectl -n <namespace> delete pod management-natscluster-1 management-natscluster-2 management-natscluster-3
```

DataPower operator fails to start

There is a known issue on Kubernetes that can cause the DataPower operator to fail to start. In this case, the DataPower operator pods can fail to schedule, and display the status message: `no nodes match pod topology spread constraints (missing required label)`. For example:

```
0/15 nodes are available: 12 node(s) didn't match pod topology spread constraints (missing required label),
3 node(s) had taint {node-role.kubernetes.io/master: }, that the pod didn't tolerate.
```

You can workaround the issue by editing the DataPower operator deployment and reapplying it, as follows:

1. Delete the DataPower operator deployment, if deployed already:

   ```
   kubectl delete -f ibm-datapower.yaml -n <namespace>
   ```

2. Open `ibm-datapower.yaml`, and locate the `topologySpreadConstraints:` section. For example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: zone
     whenUnsatisfiable: DoNotSchedule
   ```

3. Replace the values for `topologyKey:` and `whenUnsatisfiable:` with the corrected values that are shown in the following example:

   ```
   topologySpreadConstraints:
   - maxSkew: 1
     topologyKey: topology.kubernetes.io/zone
     whenUnsatisfiable: ScheduleAnyway
   ```

4. Save `ibm-datapower.yaml` and deploy the file to the cluster:

   ```
   kubectl apply -f ibm-datapower.yaml -n <namespace>
   ```

Unexpected behavior in Cloud Manager and API Manager UIs after upgrade

Stale browser cache issues can cause problems after an upgrade. To remedy this problem, clear your browser cache, and open a new browser window.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Portal sites failed to be upgraded successfully

If one or more of the Portal sites failed to be upgraded successfully, check the portal-www admin container logs to see what prevented the site upgrade from completing successfully.

To trigger the site upgrade again, exec into the portal-www pod admin container and run the following command:

```
upgrade_devportal -s <site_uuid> -p <platform>
```

where:

- *<site_uuid>* can be obtained by running the command: `list_sites`
- *<platform>* can be obtained by running the command: `list_platforms`

- **Enabling gateway peering and verifying cluster status**
  Scale the replicas to 0 and back up to reset gateway-peering.

Enabling gateway peering and verifying cluster status

Scale the replicas to 0 and back up to reset gateway-peering.

Before you begin

This task is only needed under certain scenarios, such as when you rotate the root CA, and is not automatically required for an upgrade.

About this task

Follow these steps to fix gateway peering. When the ingress issuer changes, the gateway pods must be scaled down and back up. This process causes 5 to 10 minutes of API downtime.

Procedure

1. Verify that the management, portal, and analytics subsystems report `Running` status.
2. Scale down the gateway firmware containers by editing the gateway CR and setting `replicaCount` to 0:

```
kubectl edit gw <gw-cr-name>
```

For example:

```
...
spec:
  replicaCount: 0
...
```

3. Wait for the gateway firmware pods to scale down and terminate. Ensure that the gateway firmware pods are terminated before you move to next step.
4. Scale up the gateway firmware containers back to their original value, or remove the `replicaCount` field if none was there before.

```
kubectl edit gw <gw-cr-name>
```

5. Wait for the cluster status to become `Running`. If you performed an upgrade, verify that the `RECONCILED VERSION` displays the new version number.
For example:

```
kubectl get apic -n <namespace>
```

```
NAME                                                    READY   STATUS    VERSION              RECONCILED VERSION
AGE
analyticscluster.analytics.apiconnect.example.com/analytics   8/8     Running   10.0.8.2-ifix1   10.0.8.2-ifix10-1074
121m

NAME                                        PHASE     READY   SUMMARY                          VERSION    AGE
datapowerservice.datapower.example.com/gw1   Running   True    StatefulSet replicas ready: 1/1   10.0.8.2-ifix1   100m

NAME                                        PHASE     LAST EVENT   WORK PENDING   WORK IN-PROGRESS   AGE
datapowermonitor.datapower.example.com/gw1   Running                false          false              100m

NAME                                            READY   STATUS    VERSION              RECONCILED VERSION      AGE
gatewaycluster.gateway.apiconnect.example.com/gw1   2/2     Running   10.0.8.2-ifix1   10.0.8.2-ifix1-1074  100m

NAME                                              READY   STATUS    VERSION              RECONCILED VERSION      AGE
managementcluster.management.apiconnect.example.com/m1   16/16   Running   10.0.8.2-ifix1   10.0.8.2-ifix1-1074   162m

NAME                                            READY   STATUS    VERSION              RECONCILED VERSION      AGE
portalcluster.portal.apiconnect.example.com/portal   3/3     Running   10.0.8.2-ifix1   10.0.8.2-ifix1-1074   139m
```

Troubleshooting: If you find your gateways do not sync with your management service, see known upgrade issues.

Upgrading on OpenShift and Cloud Pak for Integration

You can upgrade API Connect in an OpenShift environment and as part of IBM Cloud Pak for Integration.

- **Planning your API Connect upgrade on OpenShift**
  Review the supported upgrade paths and other upgrade considerations on OpenShift or Cloud Pak for Integration.
- **Pre-upgrade preparation and checks on OpenShift**
  Prepare your API Connect deployment on OpenShift or Cloud Pak for Integration for upgrade.
- **Upgrading API Connect on OpenShift**
  Upgrade your API Connect installation to a newer version on OpenShift in an online (connected to the internet) environment.
- **Troubleshooting upgrade on OpenShift**
  Review the following troubleshooting tips if you encounter a problem during API Connect upgrade on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Planning your API Connect upgrade on OpenShift

Review the supported upgrade paths and other upgrade considerations on OpenShift or Cloud Pak for Integration.

Supported upgrade paths for API Connect

Table 1 lists the supported upgrade paths for API Connect and explains whether you can upgrade directly or an interim upgrade is required.

Table 1. Supported upgrade paths on OpenShift

Upgrade from:	How to upgrade to 10.0.8.2-ifix1
• 10.0.8.1 • 10.0.8.0 • 10.0.5.8 • 10.0.5.7 • 10.0.5.6 • 10.0.5.5 • 10.0.5.4	Note: Before upgrading to APIC v10.0.8.2-ifix1, you must run the `apicops pre-upgrade` command to check for: • Encryption-related issues • Invalid gateway-extensions Complete the procedure in Upgrading on OpenShift and Cloud Pak for Integration.

Upgrade from:	How to upgrade to 10.0.8.2-ifix1
10.0.6.0	Complete two upgrades, making sure to perform the additional steps to preserve and re-create your SFTP backup configuration: 1. Upgrade to version 10.0.7.0 as explained in Upgrading on OpenShift and Cloud Pak for Integration in the API Connect 10.0.7.0 documentation. If you used SFTP backups for the Management subsystem in 10.0.6.0, you must temporarily remove the SFTP backup configuration before running the upgrade to 10.0.7.0: a. Edit the Management subsystem CR (or the `spec.management` section of your top-level `apiconnectcluster` CR), delete the `databaseBackup` section, and save it so you can restore it later. b. Add the following annotation into that CR: `apiconnect-operator/backups-not-configured: "true"` 2. Upgrade to the current release by completing the procedures in Upgrading on OpenShift and Cloud Pak for Integration. 3. Restore your SFTP backup configuration in the new version of API Connect: a. Edit the Management subsystem CR (or the `spec.management` section of your top-level `apiconnectcluster` CR), and add the preserved `databaseBackup` section. b. Delete the `apiconnect-operator/backups-not-configured: "true"` annotation.
10.0.5.3 or earlier	Complete two upgrades: 1. Upgrade to version 10.0.5.8 or later as explained in Upgrading on OpenShift and Cloud Pak for Integration in the API Connect 10.0.5.x documentation. 2. Upgrade to the current release by completing the procedures in Upgrading on OpenShift and Cloud Pak for Integration. Note: If you are on version 10.0.5.4 or 10.0.5.5, upgrading to version 10.0.8.2-ifix1 requires updating to version 10.0.5.8 first.

Supported DataPower Gateway versions

You can use any combination of API Connect 10.0.8.x with DataPower 10.6.0.y.

Before you upgrade, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. When you find the information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

Version and platform compatibility

Be sure to review Operator, CASE, and platform requirements for upgrading for the latest information on OpenShift and API Connect requirements.

Important upgrade considerations

Carefully review the following items, to plan and prepare for your upgrade.

Analytics backup changes

In V10.0.8, the analytics database backup functions moved from the API Connect operator to the analytics subsystem pods. This change has two implications:

- It is not possible to restore pre-V10.0.8 analytics database backups to a V10.0.8 or later analytics subsystem.
- During the upgrade procedure, after the API Connect operator is upgraded but before the analytics subsystems are upgraded, the analytics subsystem CR status reports

```
The backup and restore functionality for the API Analytics subsystem has been moved from the IBM API Connect operator
into the API Analytics microservices.
This means that the v5.2-sc2 operator cannot support backup and restore on versions before 10.0.8.
Update to 10.0.8 for scheduled backups to continue.
```

If you are using the top-level CR, then the `APIConnectCluster` CR reports a status of `Pending` until the analytics subsystems are upgraded to V10.0.8.

Upgrading multiple instances of API Connect

- If a single operator manages multiple instances, all of those instances must be upgraded, one at a time, as soon as possible.
  The operator should not be managing an operand based on an older version any longer than necessary.
- Ensure that each instance is fully upgraded before you start the upgrade on the next instance.

Top-level CR deployment profiles n3xc16.m48 and n3xc12.m40 deprecated

The top-level CR deployment profiles `n3xc16.m48` and `n3xc12.m40` are deprecated, and replaced with the profiles `n3xc16.m64` and `n3xc12.m56`. It is recommended to switch to one of these new profiles after upgrade to V10.0.8 is completed. For information about switching profile, see Changing deployment profiles on OpenShift top-level CR.

Analytics `n3xc4.m16` component profile is deprecated

The analytics `n3xc4.m16` profile is deprecated in 10.0.8.0. If you use this profile, then it is recommended to switch to the `n3xc4.m32` profile. You can switch profile either before or after upgrade to V10.0.8. For information about switching profile, see Changing deployment profiles on Kubernetes and OpenShift.

Extra persistent storage required for analytics local backups

If analytics database backups are configured, then beginning with 10.0.8.0, an extra PV is required to store local backups and prepare them for transmission to your remote SFTP server or object-store.

Before you upgrade, verify that you have an extra PV available for your analytics subsystem local backups, and decide how much space to allocate to it. To estimate storage requirements for your local backups, see Estimating storage requirements.

The default size of the new PVC is 150Gi. You can override the size to increase it during the upgrade procedure.

API transaction failure during the upgrade of gateway

The gateway subsystem remains available and continues processing API calls during the upgrade of the management, portal, and analytics subsystems. However, a few API transactions might fail during the upgrade of the gateway.

When you upgrade a cluster of gateway pods, a few API transactions might fail. During the upgrade, Kubernetes removes the pod from the load balancer configuration, deletes the pod, and then starts a new pod. The steps are repeated for each pod. Socket hang-ups occur on transactions that are in process at the time the pod is terminated.

The number of transactions that fail depends on the rate of incoming transactions, and the length of time that is needed to complete each transaction. Typically the number of failures is a small percentage. This behavior is expected during an upgrade. If the failure level is not acceptable, schedule the upgrade during an off-hours maintenance window.

DataPower Gateway supports long-lived connections such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when you upgrade. Workloads with long-lived connections are more vulnerable to failed API transactions during upgrading.

You can limit the number of failed API transactions during the upgrade by using the DataPower Operator's **`lifecycle`** property to configure the **`preStop`** container lifecycle hook on the gateway pods. This approach mitigates the risk of API failures during the rolling update of the gateway StatefulSet by sleeping the pod for a span of time, allowing in-flight transactions to complete before the SIGTERM is delivered to the container. While this feature does not guarantee no in-flight API call failures, it does provide some mitigation for in-flight transactions that can complete successfully within the configured time window. For more information, see Delaying SIGTERM with preStop in the DataPower documentation.

OAuth provider resources with **`api.securityDefintions`**

If you have native OAuth providers that are configured with the **`api.securityDefintions`** field assigned, then upgrade fails. Before upgrade, remove all **`api.securityDefintions`** from all native OAuth providers that you configured in the Cloud Manager and API Manager UIs:

- Configuring a native OAuth provider in the Cloud Manager UI
- Configuring a native OAuth provider in the API Manager UI

Switch to the source view and delete any **`securityDefintions`** sections that are present.

Extra backup folder appended to management database backup path

When you upgrade to V10.0.7.0 or later with S3 backups configured, an extra backup path folder /edb is appended to your backup path. The /edb path distinguishes new EDB backups from your previous management backups.

Extra persistent storage requirement for management subsystem

Upgrading to V10.0.7.0 or later requires extra persistent storage space for the management subsystem. Verify that your environment has at least as much extra capacity as the capacity assigned to your existing Postgres PVC:

```
kubectl get pvc -n <namespace>
```

```
NAME                                      STATUS   VOLUME                CAPACITY   ACCESS MODES   STORAGECLASS    AGE
def-management-site1-postgres             Bound    local-pv-7b528204     244Gi      RWO            local-storage   125d
def-management-site1-postgres-pgbr-repo   Bound    local-pv-8d425510     244Gi      RWO            local-storage   125d
def-management-site1-postgres-wal         Bound    local-pv-ee8feb38     244Gi      RWO            local-storage   125d
```

Analytics persistent queue enablement requires extra PV. Upgrades from V10.0.5

The analytics persistent queue feature is enabled during the upgrade (if it was not already enabled). This feature requires an extra Physical Volume (PV). Before you upgrade from V10.0.5.x, ensure that your environment has an available PV.

- **Operator, CASE, and platform requirements for upgrading**
  Before you upgrade API Connect on OpenShift Container Platform, verify that you are using the correct operator, CASE file (for air-gapped upgrades), and OpenShift version.

Operator, CASE, and platform requirements for upgrading

Before you upgrade API Connect on OpenShift Container Platform, verify that you are using the correct operator, CASE file (for air-gapped upgrades), and OpenShift version.

Supported versions of operators for API Connect

Table 1 lists the operators that are used for the newest version of API Connect

Table 1. Operators for installing and upgrading API Connect

API Connect version	API Connect Operator channel	API Connect Operator version	Data Power version	DataPower Operator version	Foundational services CASE version
10.0.8.2-ifix1	v5.4-sc2	5.4.1	10.6.0.4	1.11.5	4.6.x

You can run the API Connect operator and subsystems at different versions. The following table shows the supported combinations:

Table 2. API Connect versions supported by the API Connect operators.

API Connect Operator version	API Connect version
5.4.1	• 10.0.8.2-ifix1 • 10.0.8.1 • 10.0.8.0
5.3.0	• 10.0.8.1 • 10.0.8.0
5.2.0	• 10.0.8.0

CASE versions required for air-gapped installation and upgrade

Table 2 lists the required CASE file for each API Connect release:

Table 3. CASE versions for air-gapped deployments

API Connect version	API Connect CASE version	Foundational services CASE version	EDB CASE version
10.0.8.2-ifix1	5.4.1	`4.6.x`	5.12.0+20250113.184627.2261

Supported versions of Red Hat OpenShift Container Platform

Following table provides a quick reference of the supported OpenShift versions for API Connect:

Table 4. API Connect and OpenShift Container Platform (OCP) compatibility

API Connect version	OCP 4.10	OCP 4.12	OCP 4.14	OCP 4.15	OCP 4.16	OCP 4.17	OCP4.18
10.0.5.4	✓	✓					
10.0.5.5	✓	✓	✓				
10.0.5.6		✓	✓				
10.0.5.7		✓	✓				
10.0.5.8		✓	✓		✓		
10.0.6.0	✓	✓					
10.0.7.0		✓	✓				
10.0.8.0		✓	✓	✓	✓		
10.0.8.1		✓	✓	✓	✓	✓	
10.0.8.2-ifix1		✓	✓	✓	✓	✓	✓

Upgrading OpenShift to support a newer version of API Connect

When you upgrade API Connect, both your current deployment and your target release must support the same version of OpenShift. After the API Connect upgrade, you can optionally update OpenShift to the highest version supported by the new release of API Connect.

During the upgrade process, it is possible that API Connect is temporarily running on an unsupported version of OpenShift because you must upgrade API Connect before you upgrade OpenShift.

For example, suppose that your current deployment is running API Connect 10.0.5.4 on OpenShift 4.10 and you want to upgrade to API Connect 10.0.8.0 on OpenShift 4.14. Both versions of API Connect support OpenShift 4.12, so on the API Connect 10.0.5.4 deployment, you must upgrade OpenShift to 4.12 before you can upgrade to API Connect 10.0.8.0. After you complete the API Connect upgrade to 10.0.8.0, you can optionally upgrade to the highest supported version of OpenShift.

In this scenario, the upgrade path is as follows:

1. On the API Connect 10.0.5.4 deployment, upgrade OpenShift to 4.11 and then 4.12 (interim upgrades are required).
2. Upgrade API Connect 10.0.5.4 to API Connect 10.0.8.0.
3. Optionally upgrade OpenShift from 4.12 to 4.13, and then 4.14.

For OpenShift upgrade instructions, see the Red Hat OpenShift documentation.

Pre-upgrade preparation and checks on OpenShift

Prepare your API Connect deployment on OpenShift or Cloud Pak for Integration for upgrade.

This topic covers all the preparation steps you must complete before you can start the upgrade process.

Before following the steps in this topic, review the Planning your API Connect upgrade on OpenShift to ensure that you are following a supported upgrade path and that you understand important changes that might affect your deployment.

Run the Pre-upgrade health-checks during your upgrade planning stage to identify any problems as early as possible. Run the checks again just before upgrade to confirm API Connect is still ready for upgrade.

Obtaining upgrade files

1. Obtain the API Connect files from IBM Fix Central.
   From the IBM Fix Central site, download the following files:

   IBM® API Connect *<version>* for Containers
   : Docker images for all API Connect subsystems. Filename is apiconnect-image-tool_*<version>*.

   IBM® API Connect *<version>* Operator Release Files for Containers
   : Kubernetes operators and API Connect Custom Resource (CR) templates. Filename is apiconnect-operator-release-files_*<version>*.

   IBM API Connect *<version>* Security Signature Bundle File
   : Signature files for verifying the integrity of your downloads.
   Filename is signatures_*<version>*.

   IBM API Connect *<version>* Toolkit for *<operating_system>*
   : Toolkit command-line utility. Packaged as a stand-alone file, or with API Designer:
   - IBM API Connect *<version>* Toolkit for *<operating_system>*

- IBM API Connect *<version>* Toolkit Designer for *<operating_system>*
  Filename is toolkit-...*<operating system>*_*<version>*.
  Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI as explained in Installing the toolkit.

IBM API Connect *<version>* Local Test Environment
Optional test environment for testing locally as explained in Testing an API with the Local Test Environment.
Filename is apic-lte-*<operating system>*_*<version>*.

2. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
3. Extract the **IBM API Connect *<version>* Operator Release Files for Containers** that you downloaded in step 1.
   Create a directory called **helper_files** and extract the contents of **helper_files.zip** from the release_files.zip into the **helper_files** directory.

Pre-upgrade health-checks

1. Verify that the API Connect operator and subsystems are all running.
   To verify the health of each subsystem, run the following commands:

```
oc get ManagementCluster -n <management namespace>
oc get GatewayCluster -n <gateway namespace>
oc get PortalCluster -n <portal namespace>
oc get AnalyticsCluster -n <analyticsnamespace>
```

   Confirm that all pods are **READY**, for example:

```
oc get PortalCluster -n apic
NAME      READY   STATUS    VERSION    RECONCILED VERSION   AGE
portal    3/3     Running   10.0.8.2-ifix1   10.0.8.2-ifix1-95    57m
```

2. **Upgrading from V10.0.5.x:** Verify that the management subsystem's **pgcluster** is working correctly:
   a. Get the name of the **pgcluster**:

```
oc get pgcluster -n <management namespace>
```

   The response displays the name of the postgres cluster that is running in the specified namespace.

   b. Check the status of the **pgcluster**:

```
oc get pgcluster <pgcluster_name> -n <APIC_namespace> -o yaml | grep status -A 2 | tail -n3
```

   A successful response looks like the following example, where the state is **Initialized**:

```
status:
    message: Cluster has been initialized
    state: pgcluster Initialized
```

   Important: If the **pgcluster** returns any other state, then do not proceed with the upgrade.
   - If backup or restore jobs are running, wait until they complete and then check the status again. Do not proceed with the upgrade until the status is **Initialized**.
   - If all background jobs are complete but the **pgcluster** does not return **state: pgcluster Initialized**, then contact IBM Support for assistance.

3. Run the pre-upgrade health check:
   Note: If you have a 2DCDR deployment, run this check only on the active management subsystem.
   a. Verify that the **apicops** utility is installed and that you have the latest version by running the following command:

```
apicops --version
```

   For more information about the **apicops** utility, see The API Connect operations tool: apicops.

   b. Run the following command to set the KUBECONFIG environment variable.

```
export KUBECONFIG=</path/to/kubeconfig>
```

   c. Run the **apicops pre-upgrade** check:
      i. If using the top-level CR, the check can be run against all subsystems with a single command:

```
apicops system:pre-upgrade-check apiccluster -n <namespace> [--iscp4i]
```

      Note: Before upgrading, run the following command to check for encryption issues and invalid gateway extensions:
      For a full check (requires admin password to verify topology)

```
apicops preupgrade -n <namespace>
```

      To skip topology verification (no admin password needed)

```
apicops preupgrade --no-topology -n <namespace>
```

      ii. If using individual subsystem Cs, run the check separately for each subsystem:

- Management subsystem:

```
apicops system:pre-upgrade-check management -n <namespace> [--iscp4i]
```

      Note: Before upgrading, run the following command to check for encryption issues and invalid gateway extensions:
      For a full check (requires admin password to verify topology)

```
apicops preupgrade -n <namespace>
```

      To skip topology verification (no admin password needed)

```
apicops preupgrade --no-topology -n <namespace>
```

- Portal subsystem:

  ```
  apicops system:pre-upgrade-check portal -n <namespace> [--iscp4i]
  ```

- Analytics subsystem:

  ```
  apicops system:pre-upgrade-check analytics -n <namespace> [--iscp4i]
  ```

If your API Connect installation is part of Cloud Pak for Integration, then include the argument **`--iscp4i`** when you run the command.

If your API Connect deployment is working correctly, the output shows no error messages.

If the pre-upgrade check returns any errors, then collect the output and open a support case.

Note: Cloud Pak for Integration: If you are upgrading API Connect in Cloud Pak for Integration and the pre-upgrade check indicates duplicate user accounts in the registry, resolve them now as explained in Resolving duplicate users before upgrade on Cloud Pak for Integration.

Additional pre-upgrade operations

Extra operations to review and complete before you start the upgrade.

1. **Upgrades from V10.0.5.x:** If the analytics persistent queue is not enabled, verify that you have an extra Physical Volume available.
   For more information about this requirement, see Analytics persistent queue enablement requires extra PV.
2. If analytics database backups are configured, or you want to enable them in future, then ensure that you have an extra Physical Volume available for the local backup storage. The default size is 150Gi. You can override the size during the upgrade procedure.
3. If you used any microservice image overrides in any of your API Connect subsystem CRs, remove the image overrides before upgrade.
4. If you are upgrading an air-gapped (disconnected from the internet) installation, configure the catalog sources for the target API Connect version on your bastion host or portable storage device:
   - Pre-upgrade preparation for air-gapped environment using a bastion host.
   - Pre-upgrade preparation for air-gapped environment using a portable storage device.

Backup your API Connect deployment

If upgrade fails, rollback is not possible. Before upgrade complete the disaster recovery preparation for all your subsystems.

For instructions on backing up and disaster recovery preparation, see the following topics:

- V10.0.8: Backing up, restoring, and disaster recovery.
- v10.0.7.0: Backing up, restoring, and disaster recovery
- v10.0.5.4 or later: Backups on OpenShift and Cloud Pak for Integration, Disaster recovery on OpenShift and Cloud Pak for Integration.

- **Resolving duplicate users before upgrade on Cloud Pak for Integration**
  If you are upgrading API Connect in Cloud Pak for Integration and the API Connect pre-upgrade check indicates duplicate user accounts in the registry, resolve them before you proceed with the upgrade.
- **Pre-upgrade preparation for air-gapped environment using a bastion host**
  In a disconnected, network-restricted environment, prepare your API Connect upgrade sources on your bastion host.
- **Pre-upgrade preparation for air-gapped environment using a portable storage device**
  In a disconnected, network-restricted environment, prepare your API Connect upgrade sources on your portable storage device.

Resolving duplicate users before upgrade on Cloud Pak for Integration

If you are upgrading API Connect in Cloud Pak for Integration and the API Connect pre-upgrade check indicates duplicate user accounts in the registry, resolve them before you proceed with the upgrade.

Before you begin

This task applies only when you are upgrading API Connect in Cloud Pak for Integration from 2023.2 (or earlier) to 16.1 (or later). Be sure to run the pre-upgrade check as explained in Pre-upgrade preparation and checks on OpenShift to determine whether duplicate user records exist in your deployment.

About this task

Cloud Pak for Integration uses Keycloak as an OIDC provider to authenticate users instead of IAM (Identity and Access Management). Due to differences in how Keycloak and IAM treat usernames, you might need to manually delete duplicate user accounts to ensure that users can log in after the upgrade. Review the following scenarios to determine whether you need to manually delete any user accounts.

In a user registry, each user is uniquely identified by their username. If a registry allows for case-sensitive usernames, then two user records with matching usernames that use different cases (for example, **`Alice`** and **`ALICE`**) can exist and they point to two different users. If the registry is case-insensitive, then **`Alice`** and **`ALICE`** point to the same user.

If the user registry that is backing IAM supports case-sensitive usernames, then IAM uses the case of the username from that registry. For example, if IAM is backed by an LDAP directory that contains **`ALICE`** as the username, then IAM also uses **`ALICE`** as the username.

Keycloak supports only lowercase letters for usernames, so **`ALICE`** from the LDAP directory is stored with the **`preferred_name`** **`alice`** in Keycloak.

Assuming **`ALICE`** is the username in the LDAP directory and was used by IAM before the API Connect upgrade, then API Connect might contain either **`alice`** or **`ALICE`** in its database after the upgrade, depending on how that user logged in to API Connect after the upgrade:

- If the user logged in using the Automation UI in Cloud Pak for Integration, then API Connect created a lowercase username (**alice**).
- If the user logged in using the API Connect toolkit, or an invitation from API Connect, then API Connect created a username that matches the case that was used in the underlying registry (**ALICE**).

It is possible that two user records now exist for the same user because one might be in lowercase letters and the other might be in uppercase or mixed-case letters. To determine whether duplicate user records exist and then resolve them, complete the following steps.

Procedure

1. Review the results of the pre-upgrade check to determine whether your deployment includes duplicate users.
   If duplicate user records are detected, the script returns a response similar to the following example (note the duplicated **username** setting):

```
** Checking for duplicate users in the common-services user registry **
Command: apicops-v10 duplicate-users
****************************
getDuplicateUsers::getDuplicateUsers Entering
Found duplicate user entries: [
    {
        "username": "alice",
        "id": "291339db-acd9-493d-98c2-cfd47185588e",
        "name": "alice",

    }
]
================================================
 WARNING:
================================================
 Duplicate user records have been detected in the common-services user registry.
 Duplicate records will NOT be fixed by the system and might cause unexpected behavior.
 Please refer to product documentation on steps to clean up the duplicate entries.
================================================
****************************

***********************************************
** Finished: apicops-v10 version:pre-upgrade **
***********************************************
```

   In this example, duplicate records were detected, with the username "alice" and "ALICE".

   If your results do not indicate any duplicate users, skip the rest of this task. If the results indicate any duplicates, continue with the remaining steps to resolve the user records.

2. Decide which user account you want to preserve; the other account is considered to be the duplicate.
   You can retain either account. The choice is a matter of convenience. For example, if one of the accounts functions as the owner of organizations, you might find it simpler to retain that account to avoid having to transfer ownership to the other account. You do not have to rename the account because you delete the duplicate account; the username of the preserved account is converted to lowercase during the upgrade. For example, if you choose to preserve user "ALICE" and you delete the record for "alice" then the **username** for "ALICE" will be converted to "alice" the first time the user logs in after the upgrade.

3. If needed, transfer ownership of assets to the account that you want to preserve:
   a. Transfer ownership of catalogs.
      For instructions, see Transfer Catalog Owner on GitHub.

   b. Transfer ownership of spaces within catalogs.
      For instructions, see Transfer Space Owner on GitHub.

   c. Transfer ownership of a provider organization.
      For instructions, see Transfer Org Owner on GitHub.

4. Add any missing roles to the account that you want to preserve.
   Check the roles that are assigned to the duplicate account. If the account that you want to preserve does not include those roles, assign them now. For instructions, see Assigning roles to members in this documentation.

5. Delete the duplicate user account.
   For instructions, see Removing a user from a user registry in this documentation.

Pre-upgrade preparation for air-gapped environment using a bastion host

In a disconnected, network-restricted environment, prepare your API Connect upgrade sources on your bastion host.

Before you begin

- Review and complete all steps that are documented in Planning your API Connect upgrade on OpenShift and Pre-upgrade preparation and checks on OpenShift.
- The upgrade procedure requires you to use Red Hat Skopeo for moving container images. Skopeo is not available for Microsoft Windows, so you cannot perform this task with a Windows host.

Attention: Some steps in this task use tilde character: ~. Do not use this character within double quotation marks in any command because the tilde doesn't expand and the command might fail.

About this task

If you previously deployed or upgraded API Connect in an air-gapped environment, you can use the same bastion host as before.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in IBM API Connect Version 10 software product compatibility requirements.
      - Configure storage on the cluster and make sure that it is available.

   b. Prepare the bastion host:
      You must be able to connect your bastion host to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry) at the same time. Your host must be on a Linux x86_64 or Mac platform with any operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

      i. Ensure that the sites and ports listed in Table 1 can be reached from the bastion host:

      Table 1. Sites that must be reached from the bastion host

Site	Description
`icr.io:443`	IBM entitled registry
`quay.io:443`	Local API Connect image repository
`github.com`	CASE files and tools
`redhat.com`	Red Hat OpenShift Container Platform (OCP) upgrades

      ii. On the bastion host, install either Docker or Podman (not both).
      Docker and Podman are used for managing containers; you only need to install one of these applications.

      - To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

        ```
        yum check-update
        yum install docker
        ```

      - To install Podman, see the Podman installation instructions.
        For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

        ```
        yum install podman
        ```

      iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
      The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

      iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
      The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

      ```
      oc ibm-pak --help
      ```

   c. Set up a local image registry and credentials.
      The local Docker registry stores the mirrored images in your network-restricted environment.

      i. Install a registry, or get access to an existing registry.
      You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

      The registry product that you use must meet the following requirements:
      - Supports multi-architecture images through Docker Manifest V2, Schema 2
        For details, see Docker Manifest V2, Schema 2.
      - Is accessible from the Red Hat OpenShift Container Platform cluster nodes
      - Allows path separators in the image name

      Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

      ii. Configure the registry to meet the following requirements:
      - Supports auto-repository creation
      - Has sufficient storage to hold all of the software that is to be transferred

- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials)
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials)

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries during runtime, use an account that can read from the target local registry.

2. Mirror the cert-manager operator for Red Hat OpenShift.
Mirror the operator as explained in the Red Hat instructions: Mirroring images for a disconnected installation using the oc-mirror plugin .

   When you modify the **`ImageSetConfiguration`**, include **`openshift-cert-manager-operator`** at channel **`stable-v1`** as one of the packages, as shown in the following example:

```
packages:
- name: openshift-cert-manager-operator
  channels:
  - name: stable-v1
```

3. Set environment variables and download the CASE files.
Create environment variables to use while mirroring images, connect to the internet, and download the CASE files needed for installing API Connect.

   a. Create the following environment variables with the installer image name and the image inventory on your host:
   - API Connect:

     ```
     export CASE_NAME=ibm-apiconnect
     export CASE_VERSION=5.4.1
     export ARCH=amd64
     ```

     For information about API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

   - Foundational services:

     ```
     export CS_CASE_NAME=ibm-cp-common-services
     export CS_CASE_VERSION=4.6.3
     export CS_ARCH=amd64
     ```

     For information about IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

   - EDB:

     ```
     export EDB_CASE_NAME=ibm-cloud-native-postgresql
     export EDB_CASE_VERSION=5.2.0
     ```

   b. Connect your host to the internet (it does not need to be connected to the network-restricted environment yet).
   c. Download the CASE files to your host:
   - API Connect:

     ```
     oc ibm-pak get $CASE_NAME --version $CASE_VERSION
     ```

   - Foundational services:

     ```
     oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
     ```

   - EDB:

     ```
     oc ibm-pak get $EDB_CASE_NAME --version $EDB_CASE_VERSION
     ```

4. Generate mirror manifests.
The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before you install API Connect.

   a. Define the environment variable $TARGET_REGISTRY by running the following command:

   ```
   export TARGET_REGISTRY=<target-registry>
   ```

   Replace ***`<target-registry>`*** with the IP address (or hostname) and port of the local registry; for example: **`172.16.0.10:5000`**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **`172.16.0.10:5000/registry_ns`**.
   b. Generate mirror manifests by running the following commands:
   - API Connect:

     ```
     oc ibm-pak generate mirror-manifests $CASE_NAME --version $CASE_VERSION $TARGET_REGISTRY
     ```

   - Foundational services:

     ```
     oc ibm-pak generate mirror-manifests $CS_CASE_NAME --version $CS_CASE_VERSION $TARGET_REGISTRY
     ```

   - EDB:

     ```
     oc ibm-pak generate mirror-manifests $EDB_CASE_NAME --version $EDB_CASE_VERSION $TARGET_REGISTRY
     ```

   If you need to filter for a specific image group, add the parameter **`--filter`** ***`<image_group>`*** to the command.

   The **`generate`** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION, ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION, and ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION:
   - catalog-sources.yaml
   - catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
   - image-content-source-policy.yaml
   - images-mapping.txt

   The files are used when mirroring the images to the **`TARGET_REGISTRY`**.

5. Authenticate with the entitled registry where the images are hosted.
   a. Obtain an entitlement key for the registry where the images are hosted:
      i. Log in to the IBM Container Library.
      ii. In the Container software library, select Get entitlement key.
      iii. In the "Access your container software" section, click Copy key.
      iv. Copy the key to a safe location; you will use it to log in to `cp.icr.io` in the next step.
   b. Login to `cp.icr.io` registry:
      The image pull secret is used to authenticate with the registry and access product images.

      i. Run the following command to export the path to the file that stores the authentication credentials that are generated on a Podman or Docker login:

      ```
      export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
      ```

      The authentication file is typically located in $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

      ii. Log in to the `cp.icr.io` registry with Podman or Docker; for example:

      ```
      podman login cp.icr.io
      ```

      Use `cp` as the username and your entitlement key as the password.

6. Authenticate with the local registry.
   Log in to the local registry using an account that can write images to that registry; for example:

   ```
   podman login $TARGET_REGISTRY
   ```

   If the registry is insecure, add the following flag to the command: `--tls-verify=false`.

7. Mirror the product images.
   a. Connect the bastion host to both the internet and the restricted-network environment that contains the local registry.
   b. Run the following commands to copy the images to the local registry:
      - API Connect:

      ```
      oc image mirror \
        -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping.txt \
        -a $REGISTRY_AUTH_FILE \
        --filter-by-os '.*' \
        --skip-multiple-scopes \
        --max-per-registry=1
      ```

      - Foundational services:

      ```
      oc image mirror \
        -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping.txt \
        -a $REGISTRY_AUTH_FILE \
        --filter-by-os '.*' \
        --skip-multiple-scopes \
        --max-per-registry=1
      ```

      - EDB:

      ```
      oc image mirror \
        -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping.txt \
        -a $REGISTRY_AUTH_FILE \
        --filter-by-os '.*' \
        --skip-multiple-scopes \
        --max-per-registry=1
      ```

      Note: If the local registry does not use TLS, or your device does not trust the certificate that the local registry presents, add the `--insecure` option to the command.
      There might be a slight delay before you see a response to the command.

8. Configure the target cluster.
   Now that images are mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

   a. Log in to your Red Hat OpenShift Container Platform cluster:

   ```
   oc login <openshift_url> -u <username> -p <password> -n <namespace>
   ```

   b. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
   Updating the image pull secret provides the cluster with the credentials that are needed for pulling images from your local registry.

   Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

   ```
   oc edit image.config.openshift.io/cluster -o yaml
   ```

   and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

   ```
   spec:
     registrySources:
       insecureRegistries:
       - insecure0.svc:5001
       - <TARGET_REGISTRY>
   ```

   If the `insecureRegistries` field does not exist, you can add it.
   c. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry:
      - API Connect:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml
      ```

- Foundational services:

  ```
  oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
  ```

- EDB:

  ```
  oc apply -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/image-content-source-policy.yaml
  ```

d. Verify that each ImageContentSourcePolicy resource was created:

```
oc get imageContentSourcePolicy
```

e. Verify your cluster node status:

```
oc get MachineConfigPool -w
```

Wait for all nodes to be updated before you proceed to the next step.

9. Apply the catalog sources.
Now that the images are mirrored to the target cluster, apply the catalog sources for API Connect and Foundational services. You do not need to apply the catalog source for EDB because the API Connect operator applies that catalog source in its own namespace when the API Connect operand is created.

In the following steps, replace ***<Architecture>*** with either **amd64** or **s390x** according to your environment.

a. Export the variables for the command line to use:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.4.1
export ARCH=amd64

export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.3
export CS_ARCH=amd64
```

b. Generate the catalog source and save it in another directory in case you need to replicate this installation in the future.
Get the catalog source:

```
cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
```

You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

c. Apply the catalog sources to the cluster.
   i. Apply the universal catalog sources:

   ```
   oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

   oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
   ```

   ii. Confirm that the catalog source was created in the **openshift-marketplace** namespace:

   ```
   oc get catalogsource -n openshift-marketplace
   ```

What to do next

Upgrade your API Connect deployment, following the procedure documented in Upgrading API Connect on OpenShift.

Pre-upgrade preparation for air-gapped environment using a portable storage device

In a disconnected, network-restricted environment, prepare your API Connect upgrade sources on your portable storage device.

Before you begin

- Review and complete all steps that are documented in Planning your API Connect upgrade on OpenShift and Pre-upgrade preparation and checks on OpenShift.
- The upgrade procedure requires you to use Red Hat Skopeo for moving container images. Skopeo is not available for Microsoft Windows, so you cannot perform this task with a Windows host.

Attention: Some steps in this task use tilde character: ~. Do not use this character within double quotation marks in any command because the tilde doesn't expand and the command might fail.

About this task

If you previously deployed or upgraded API Connect in an air-gapped environment, you can use the same portable storage device as before.

Procedure

1. Set up the mirroring environment.
   a. Prepare the target cluster:
      - Deploy a supported version of Red Hat OpenShift Container Platform (OCP) as a cluster.
        For more information, see Table 2 "API Connect and OpenShift Container Platform (OCP) compatibility matrix" in Operator, CASE, and platform requirements.

- Configure storage on the cluster and make sure that it is available.

b. Prepare the portable device:
You must be able to connect your portable device to the internet and to the restricted network environment (with access to the Red Hat OpenShift Container Platform (OCP) cluster and the local registry). The portable device must be on a Linux x86_64 or Mac platform with an operating system that the Red Hat OpenShift Client supports (in Windows, execute the actions in a Linux x86_64 VM or from a Windows Subsystem for Linux terminal).

i. Check that the portable device has sufficient storage to hold all the software that is to be transferred to the local registry.
ii. On the portable device, install either Docker or Podman (not both).
Docker and Podman are used for managing containers; you can install either of these applications.

- To install Docker (for example, on Red Hat Enterprise Linux), run the following commands:

```
yum check-update
yum install docker
```

- To install Podman, see the Podman installation instructions.
For example, on Red Hat Enterprise Linux 9, install Podman with the following command:

```
yum install podman
```

iii. Install the Red Hat OpenShift Client tool (`oc`) as explained in Getting started with the OpenShift CLI.
The `oc` tool is used for managing Red Hat OpenShift resources in the cluster.

iv. Download the IBM Catalog Management Plug-in for IBM Cloud Paks version 1.1.0 or later from GitHub.
The `ibm-pak` plug-in enables you to access hosted product images, and to run `oc ibm-pak` commands against the cluster. To confirm that `ibm-pak` is installed, run the following command and verify that the response lists the command usage:

```
oc ibm-pak --help
```

c. Set up a local image registry and credentials.
The local Docker registry stores the mirrored images in your network-restricted environment.

i. Install a registry, or get access to an existing registry.
You might already have access to one or more centralized, corporate registry servers to store the API Connect images. If not, then you must install and configure a production-grade registry before proceeding.

The registry product that you use must meet the following requirements:
- Supports multi-architecture images through Docker Manifest V2, Schema 2.
For more information, see Docker Manifest V2, Schema 2.
- Is accessible from the Red Hat OpenShift Container Platform cluster nodes.
- Allows path separators in the image name.

Note: Do not use the Red Hat OpenShift image registry as your local registry because it does not support multi-architecture images or path separators in the image name.

ii. Configure the registry to meet the following requirements:
- Supports auto-repository creation.
- Has sufficient storage to hold all the software that is to be transferred.
- Has the credentials of a user who can create and write to repositories (the mirroring process uses these credentials).
- Has the credentials of a user who can read all repositories (the Red Hat OpenShift Container Platform cluster uses these credentials).

To access your registries during an air-gapped installation, use an account that can write to the target local registry. To access your registries at run time, use an account that can read from the target local registry.

2. Mirror the cert-manager operator for Red Hat OpenShift.
Mirror the operator as explained in the Red Hat instructions: Mirroring images for a disconnected installation using the oc-mirror plugin .

When you modify the `ImageSetConfiguration`, include `openshift-cert-manager-operator` at channel `stable-v1` as one of the packages, as shown in the following example:

```
  packages:
  - name: openshift-cert-manager-operator
    channels:
    - name: stable-v1
```

3. Set environment variables and download the CASE files.
Create environment variables to use while mirroring images, connect to the internet, and download the CASE files needed for installing API Connect.

a. Create the following environment variables with the installer image name and the image inventory on your portable device:
- API Connect:

```
export CASE_NAME=ibm-apiconnect
export CASE_VERSION=5.4.1
export ARCH=amd64
```

For information about API Connect CASE versions and their corresponding operators and operands, see Operator, CASE, and platform requirements.

- Foundational services:

```
export CS_CASE_NAME=ibm-cp-common-services
export CS_CASE_VERSION=4.6.3
export CS_ARCH=amd64
```

For information about IBM Cloud Pak foundational services (common services) CASE versions, see "Table 1. Image versions for offline installation" in Installing IBM Cloud Pak foundational services in an air-gapped environment in the IBM Cloud Pak foundational services documentation.

- EDB:

```
export EDB_CASE_NAME=ibm-cloud-native-postgresql
export EDB_CASE_VERSION=5.2.0
```

b. Connect your portable device to the internet (it does not need to be connected to the network-restricted environment yet).
c. Download the CASE files to your portable device:
- API Connect:

```
oc ibm-pak get $CASE_NAME --version $CASE_VERSION
```

- Foundational services:

```
oc ibm-pak get $CS_CASE_NAME --version $CS_CASE_VERSION
```

- EDB:

```
oc ibm-pak get $EDB_CASE_NAME --version $EDB_CASE_VERSION
```

4. Generate mirror manifests.
The process of mirroring images pulls the images from the internet and pushes them to your local registry. After mirroring your images, you can configure your cluster and pull the images to it before you install API Connect.

a. Define the environment variable $TARGET_REGISTRY by running the following command:

```
export TARGET_REGISTRY=<target-registry>
```

Replace **<target-registry>** with the IP address (or hostname) and port of the local registry; for example: **172.16.0.10:5000**. If you want the images to use a specific namespace within the target registry, you can specify it here; for example: **172.16.0.10:5000/registry_ns**.
b. Generate mirror manifests by running the following commands:
- API Connect:

```
oc ibm-pak generate mirror-manifests $CASE_NAME --version $CASE_VERSION $TARGET_REGISTRY
```

- Foundational services:

```
oc ibm-pak generate mirror-manifests $CS_CASE_NAME --version $CS_CASE_VERSION $TARGET_REGISTRY
```

- EDB:

```
oc ibm-pak generate mirror-manifests $EDB_CASE_NAME --version $EDB_CASE_VERSION $TARGET_REGISTRY
```

If you need to filter for a specific image group, add the parameter **--filter <image_group>** to the command.

The **generate** command creates the following files at ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION, ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION, and ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION:
- catalog-sources.yaml
- catalog-sources-linux-*<arch>*.yaml (if there are architecture-specific catalog sources)
- image-content-source-policy.yaml
- images-mapping-to-filesystem.txt
- images-mapping-from-filesystem.txt

The files are used when mirroring the images to the **TARGET_REGISTRY**.

5. Authenticate with the entitled registry where the images are hosted.
a. Obtain an entitlement key for the registry where the images are hosted:
i. Log in to the IBM Container Library.
ii. In the Container software library, select Get entitlement key.
iii. In the "Access your container software" section, click Copy key.
iv. Copy the key to a safe location; you will use it to log in to **cp.icr.io** in the next step.
b. Login to **cp.icr.io** registry:
The image pull secret is used to authenticate with the registry and access product images.

i. Run the following command to export the path to the file that stores the authentication credentials that are generated on a Podman or Docker login:

```
export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
```

The authentication file is typically located in $HOME/.docker/config.json on Linux or %USERPROFILE%/.docker/config.json on Windows.

ii. Log in to the **cp.icr.io** registry with Podman or Docker; for example:

```
podman login cp.icr.io
```

Use **cp** as the username and your entitlement key as the password.

6. Mirror the images from the internet to the portable device.
a. Define the environment variable $IMAGE_PATH by running the following command:

```
export IMAGE_PATH=<image-path>
```

where **<image-path>** indicates where the files are stored on the portable device's file system.
b. Mirror the images to the portable device:
- API Connect:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

- Foundational services:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

- EDB:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping-to-filesystem.txt \
  --filter-by-os '.*' \
  -a $REGISTRY_AUTH_FILE \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --dir "$IMAGE_PATH"
```

There might be a slight delay before you see a response to the command.

7. Move the portable device to the restricted-network environment.
   The procedure depends on the type of device that you are using:
   If you are using a portable computer, disconnect the device from the internet and connect it to the restricted-network environment. The same environment variables can be used.

   If you are using portable storage, complete the following steps:

   a. Transfer the following files to a device in the restricted-network environment:
      - The `~/.ibm-pak` directory.
      - The contents of the *`<image-path>`* that you specified in the previous step.
   b. Create the same environment variables as on the original device; for example:
      - API Connect:

        ```
        export CASE_NAME=ibm-apiconnect
        export CASE_VERSION=5.4.1
        export ARCH=amd64
        ```

      - Foundational services:

        ```
        export CS_CASE_NAME=ibm-cp-common-services
        export CS_CASE_VERSION=1.15.10
        export CS_ARCH=amd64
        ```

      - EDB:

        ```
        export EDB_CASE_NAME=ibm-cp-common-services
        export EDB_CASE_VERSION=1.15.10
        export EDB_ARCH=amd64
        ```

      - Registry:

        ```
        export REGISTRY_AUTH_FILE=$HOME/.docker/config.json
        ```

      - Image path:

        ```
        export IMAGE_PATH=<image-path>
        ```

8. Authenticate with the local registry.
   Log in to the local registry using an account that can write images to that registry; for example:

   ```
   podman login $TARGET_REGISTRY
   ```

   If the registry is insecure, add the following flag to the command: `--tls-verify=false`.

9. Mirror the product images to the target registry.
   a. Mirror the product images to the target registry.
      i. If you are using a portable computer, connect it to the restricted-network environment that contains the local registry.
      If you are using portable storage, you already transferred files to a device within the restricted-network environment.

      ii. Run the following commands to copy the images to the local registry:
      - API Connect:

        ```
        oc image mirror \
          -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/images-mapping-from-filesystem.txt \
          -a $REGISTRY_AUTH_FILE \
          --filter-by-os '.*' \
          --skip-multiple-scopes \
          --max-per-registry=1 \
          --from-dir "$IMAGE_PATH"
        ```

      - Foundational services:

        ```
        oc image mirror \
          -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/images-mapping-from-filesystem.txt \
          -a $REGISTRY_AUTH_FILE \
          --filter-by-os '.*' \
          --skip-multiple-scopes \
          --max-per-registry=1 \
          --from-dir "$IMAGE_PATH"
        ```

      - EDB:

```
oc image mirror \
  -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/images-mapping-from-filesystem.txt \
  -a $REGISTRY_AUTH_FILE \
  --filter-by-os '.*' \
  --skip-multiple-scopes \
  --max-per-registry=1 \
  --from-dir "$IMAGE_PATH"
```

Note: If the local registry does not use TLS, or your device does not trust the certificate that the local registry presents, add the `--insecure` option to the command.
There might be a slight delay before you see a response to the command.

10. Configure the target cluster.
Now that images are mirrored to the local registry, the target cluster must be configured to pull the images from it. Complete the following steps to configure the cluster's global pull secret with the local registry's credentials and then instruct the cluster to pull the images from the local registry.

    a. Log in to your Red Hat OpenShift Container Platform cluster:

    ```
    oc login <openshift_url> -u <username> -p <password> -n <namespace>
    ```

    b. Update the global image pull secret for the cluster as explained in the Red Hat OpenShift Container Platform documentation.
    Updating the image pull secret provides the cluster with the credentials that are needed for pulling images from your local registry.

    Note: If you have an insecure registry, add the registry to the cluster's `insecureRegistries` list by running the following command:

    ```
    oc edit image.config.openshift.io/cluster -o yaml
    ```

    and add the TARGET_REGISTRY to `spec.registrySources.insecureRegistries` as shown in the following example:

    ```
    spec:
      registrySources:
        insecureRegistries:
        - insecure0.svc:5001
        - <TARGET_REGISTRY>
    ```

    If the `insecureRegistries` field does not exist, you can add it.

    c. Create the ImageContentSourcePolicy, which instructs the cluster to pull the images from your local registry:

    - API Connect:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/$CASE_NAME/$CASE_VERSION/image-content-source-policy.yaml
      ```

    - Foundational services:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/$CS_CASE_NAME/$CS_CASE_VERSION/image-content-source-policy.yaml
      ```

    - EDB:

      ```
      oc apply -f ~/.ibm-pak/data/mirror/$EDB_CASE_NAME/$EDB_CASE_VERSION/image-content-source-policy.yaml
      ```

    d. Verify that each ImageContentSourcePolicy resource was created:

    ```
    oc get imageContentSourcePolicy
    ```

    e. Verify your cluster node status:

    ```
    oc get MachineConfigPool -w
    ```

    Wait for all nodes to be updated before you proceed to the next step.

11. Apply the catalog sources.
Now that the images are mirrored to the target cluster, apply the catalog sources for API Connect and Foundational services. You do not need to apply the catalog source for EDB because the API Connect operator applies that catalog source in its own namespace when the API Connect operand is created.

    In the following steps, replace `<Architecture>` with either `amd64` or `s390x` according to your environment.

    a. Export the variables for the command line to use:

    ```
    export CASE_NAME=ibm-apiconnect
    export CASE_VERSION=5.4.1
    export ARCH=amd64

    export CS_CASE_NAME=ibm-cp-common-services
    export CS_CASE_VERSION=4.6.3
    export CS_ARCH=amd64
    ```

    b. Generate the catalog source and save it in another directory in case you need to replicate this installation in the future.
    Get the catalog source:

    ```
    cat ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

    cat ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
    ```

    You can also navigate to the directory in your file browser to copy these artifacts into files that you can keep for re-use or for pipelines.

    c. Apply the catalog sources to the cluster.

    i. Apply the universal catalog sources:

    ```
    oc apply -f ~/.ibm-pak/data/mirror/${CASE_NAME}/${CASE_VERSION}/catalog-sources.yaml

    oc apply -f ~/.ibm-pak/data/mirror/${CS_CASE_NAME}/${CS_CASE_VERSION}/catalog-sources.yaml
    ```

    ii. Confirm that the catalog source was created in the `openshift-marketplace` namespace:

```
oc get catalogsource -n openshift-marketplace
```

What to do next

Upgrade your API Connect deployment, following the procedure documented in Upgrading API Connect on OpenShift.

Upgrading API Connect on OpenShift

Upgrade your API Connect installation to a newer version on OpenShift in an online (connected to the internet) environment.

Before you begin

Review and complete all steps that are documented in Planning your API Connect upgrade on OpenShift and Pre-upgrade preparation and checks on OpenShift.

- If any subsystem database backups are running or are scheduled to run within a few hours, do not start the upgrade process.
- Do not perform maintenance tasks such as updating certificates, restoring subsystem databases from backup, or triggering subsystem database backups at any time while you are upgrading API Connect.

Procedure

1. If you did not run the Pre-upgrade health-checks recently, run them now.
2. If you have a two data center disaster recovery deployment, then upgrade the warm-standby data center first.
   See the special steps for 2DCDR upgrades:
   - Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.5
   - Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.7 or later
3. **Upgrading from 10.0.5.x:** Install the cert-manager operator for Red Hat OpenShift by completing the following steps:
   a. Log in to the OpenShift Container Platform web console.

   b. Click Operators > OperatorHub.

   c. In the filter box, type: `cert-manager Operator for Red Hat OpenShift`.

   d. Select cert-manager Operator for Red Hat OpenShift and click Install.

   e. On the Install Operator page, complete the following steps:
      i. Update the Update channel if needed. The channel defaults to `stable-v1`, which installs the latest stable release of the cert-manager Operator for Red Hat OpenShift.

      ii. Select the Installed Namespace for the operator.
      The default operator namespace is `cert-manager-operator`; if that namespace doesn't exist, it is created for you.

      iii. Select an Update approval strategy:
         - Automatic: allow Operator Lifecycle Manager (OLM) to automatically update the operator when a new version is available.
         - Manual: require a user with the appropriate credentials to approve all operator updates.

      iv. Click Install.

   f. Verify the new cert-manager installation by completing the following steps:
      i. Click Operators > Installed Operators.

      ii. Verify that `cert-manager Operator for Red Hat OpenShift` is listed with a Status of `Succeeded` in the `cert-manager-operator` namespace.

      iii. Verify that cert-manager pods are up and running with:

      ```
      oc get pods -n cert-manager
      ```

      For a successful installation, the response looks like the following example:

      ```
      NAME                                       READY   STATUS    RESTARTS   AGE
      cert-manager-bd7fbb9fc-wvbbt               1/1     Running   0          3m39s
      cert-manager-cainjector-56cc5f9868-7g9z7   1/1     Running   0          4m5s
      cert-manager-webhook-d4f79d7f7-9dg9w       1/1     Running   0          4m9s
      ```

   g. Remove the obsolete cert-manager operator (which was provided by IBM Cloud Pak foundational services).
   If you previously deployed the IBM Cloud Pak foundational services operator and the API Connect operator in the same namespace, you might need to manually remove the instance of `ibm-cert-manager-operator` that was installed in `ibm-common-services`. Complete the following steps to check for the operator and then remove it:

      i. Run the following command to get the list of installed cert-manager operators:

      ```
      oc get pods -A | grep cert-manager-operator
      ```

      If the response lists the `ibm-cert-manager-operator` operator, then proceed to the next step to remove it.

      ```
      cert-manager-operator   cert-manager-operator-controller-manager-68ccfc6dd9-2ww4t      2/2     Running     0
      47h
      ibm-common-services     ibm-cert-manager-operator-7c848f5d6c-xtdsb                    1/1     Running     0
      2d
      ```

      ii. Delete the `ibm-cert-manager-operator` operator by running the following commands:

```
oc delete subs ibm-cert-manager-operator -n ibm-common-services
oc get csv  -n ibm-common-services | grep ibm-cert-manager-operator | awk '{ print $1}' | xargs oc delete csv -n
ibm-common-services
```

4. Update the operators for the API Connect deployment.
   API Connect uses three operators; which you update by selecting a newer version for the operator channel. Update the channels in the following sequence:
   a. DataPower: set the channel to v1.11-sc2
   b. API Connect: set the channel to v5.4-sc2
   c. Foundational services: set the channel to v4.6
      Be sure to update the Foundational services operator channel in all namespaces.

   Complete the following steps to update a channel:

   a. Click Operators > Installed Operators.
   b. Select the operator to be upgraded.
   c. Select the Subscription tab.
   d. In the Update channel list, select the new channel version.

   If you previously chose automatic subscriptions, the operator version upgrades automatically when you update the operator channel. If you previously chose manual subscriptions, OpenShift OLM notifies you that an upgrade is available and then you must manually approve the upgrade before proceeding.

   Wait for the operators to update, for the pods to restart, and for the instances to display the **Ready** status. Both the API Connect and DataPower channels must be changed before either operator upgrades. The upgrade of both operators begins when the channel is changed for both operators.

   Troubleshooting: See Troubleshooting upgrade on OpenShift.

   Upgrading from V10.0.5.x: Upgrading to V10.0.8 involves migrating from Crunchy Postgres to EDB. After the API Connect operator upgrades, the **apiconnectcluster** will be in a pending state, and the **managementcluster** will be in a warning state with the following message:

```
message: management CR is not tracking status, please change CR spec.version
    as soon as possible. Refer https://shortlink.url for details
reason: DatabaseSwitchMode
```

   This issue applies only to upgrades from V10.0.5.x. The problem is temporary and resolves when you upgrade the API Connect management subsystem in a later step.

   You can check the status from the UI or by running the following command:

```
oc get managementcluster -o yaml
```

   Note: If analytics backups are configured, then after the API Connect operator is upgraded, the analytics CR reports a status of **Blocked** until the analytics subsystem is upgraded to V10.0.8. With top-level CR deployments, the **apiconnectcluster** CR reports **Pending** until the analytics CR is no longer **Blocked**. For more information, see Analytics backup changes.
5. Ensure that the operators and operands are working correctly before proceeding.
   Skip this step if you are upgrading from 10.0.5.x due to the issue noted in the previous step.

   - Operators: Verify that the OpenShift UI indicates that all operators are in the **Succeeded** state without any warnings.
   - If you are using the top-level CR: To verify that your API Connect cluster is working correctly, run the following command:

     ```
     oc get apiconnectcluster
     ```

     Confirm that the **apiconnectcluster** CR reports all pods as **READY**.

     ```
     NAME         READY   STATUS   VERSION    RECONCILED VERSION   MESSAGE                          AGE
     apic-ocp     n/n     Ready    10.0.8.x   10.0.8.x-258         API Connect cluster is ready   56d
     ```

   - If you are using individual subsystem CRs: To verify the health of each subsystem, run the following commands:

     ```
     oc get ManagementCluster -n <mgmt_namespace>
     oc get GatewayCluster -n <gway_namespace>
     oc get PortalCluster -n <portal_namespace>
     oc get AnalyticsCluster -n <mgmt_namespace>
     ```

     Check that all pods in each subsystem are **READY**, for example:

     ```
     oc get PortalCluster
     NAME     READY   STATUS    VERSION    RECONCILED VERSION   AGE
     portal   n/n     Running   10.0.8.2-ifix1   10.0.8.2-ifix1-95    57m
     ```

   Note: If analytics backups are configured, then after the API Connect operator is upgraded, the analytics CR reports a status of **Blocked** until the analytics subsystem is upgraded to V10.0.8. With top-level CR deployments, the **apiconnectcluster** CR reports **Pending** until the analytics CR is no longer **Blocked**. For more information, see Analytics backup changes.
6. If you are using the top-level CR (includes Cloud Pak for Integration), then update the top-level **apiconnectcluster** CR:
   The **spec** section of the **apiconnectcluster** looks like the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-production
  name: prod
  namespace: <APIC_namespace>
spec:
  license:
    accept: true
    use: production
    license: L-DZZQ-MGVN8V
  profile: n12xc4.m12
  version: 10.0.8.2-ifix1
  storageClassName: rook-ceph-block
```

a. Edit the **apiconnectcluster** CR by running the following command:

```
oc -n <APIC_namespace> edit apiconnectcluster
```

b. Update the **spec.version** property to the version you are upgrading to.
c. If you are upgrading to a version of API Connect that requires a new license, update the **spec.license** property accordingly.
For the list of licenses, see API Connect licenses.

d. Optional: Set local analytics backups PVC size.
By default the new PVC that is created for the analytics subsystem's local database backups is set to 150Gi. If you want to specify a larger size, then add the following to the CR **spec.analytics** section:

```
  storage:
    backup:
      volumeClaimTemplate:
        storageClass: <storage class>
        volumeSize: <size>
```

where:
- *<storage class>* is the same as used by your other analytics PVCs.
- *<size>* is the size. For example: **500Gi**. See Estimating storage requirements.

e. Optional: If you are upgrading API Connect in Cloud Pak for Integration and want to preserve the Cloud Pak endpoints during the upgrade, add the **deprecatedCloudPakRoute** object to the **spec.management** section of the CR:
Beginning with version 10.0.7.0, API Connect no longer uses the Cloud Pak cpd routes for endpoints when deployed as a component of Cloud Pak for Integration. Instead, the API Management component uses the typical default API Connect routes (or the custom endpoints that are configured in the CR). You can enable the use of Cloud Pak endpoints when you upgrade the API Management component in Cloud Pak for Integration 2023.4.1 or later.

Attention: If you choose to accept the new endpoints (without the Cloud Pak cpd routes), skip this step. However, if you previously configured your own OIDC user registry, be sure to update the **redirect_uri** to reflect the new API Connect endpoint.
To preserve the Cloud Pak endpoints during the upgrade, insert the **deprecatedCloudPakRoute** object into the **spec.management** section as shown in the following example:

```
apiVersion: apiconnect.ibm.com/v1beta1
kind: APIConnectCluster
metadata:
  labels:
    app.kubernetes.io/instance: apiconnect
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: apiconnect-minimum
  name: <name_of_your_instance>
  namespace: <APIC-namespace>
spec:
  license:
    accept: true
    license: L-MMBZ-295QZQ
    metric: PROCESSOR_VALUE_UNIT
    use: nonproduction
  profile: n1xc7.m48
  version: 10.0.8.0
  storageClassName: <default-storage-class>
  management:
    deprecatedCloudPakRoute:
      enabled: true
      cloudPakEndpoint:
        hosts:
        - name: cpd-apic.apps.admin-<domain>.com
```

Tip: If you want to maintain the same CPD endpoint, ensure that the **cloudPakEndpoint** hostname is identical to the legacy CPD route name.
f. Optional: If you chose to preserve the Cloud Pak endpoints during the upgrade and want to add a custom certificate for the Cloud Pak route, complete the following steps:
    i. Create a Cloud Pak certificate that is signed by a Cloud Pak CA, as in the following example:

```
---
apiVersion: cert-manager.io/v1
kind: Issuer
metadata:
 name: custom-cpd-ca
 namespace: apic
spec:
 selfSigned: {}
---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: custom-cpd
  namespace: apic
spec:
  commonName: small-mgmt-cpd
  dnsNames:
  - cpd-apic.apps.admin-apickeycloak.cp.fyre.ibm.com
  duration: 17520h0m0s
  issuerRef:
    kind: Issuer
    name: custom-cpd-ca
  privateKey:
    algorithm: RSA
    rotationPolicy: Always
    size: 2048
  renewBefore: 720h0m0s
  secretName: custom-cpd
  usages:
```

```
  - key encipherment
  - digital signature
  - server auth
```

ii. In the CR, provide the secret name within the `cloudPakEndpoint` property of the new `deprecatedCloudPakRoute` object; for example:

```
spec:
  deprecatedCloudPakRoute:
    enabled: true
    cloudPakEndpoint:
      hosts:
      - name: cpd-apic.apps.admin-<domain>.com
        secretName: custom-cpd
```

g. In the `spec.gateway` section, delete any `template` or `dataPowerOverride` override sections.
If the CR contains an override, then you cannot complete the upgrade.

h. [This step is not applicable if you are upgrading from 10.0.8.0 or 10.0.8.1 to 10.0.8.2-ifix1] If you have a two data center disaster recovery installation, and are upgrading the warm-standby, then add the annotation:

```
apiconnect-operator/dr-warm-standby-upgrade-data-deletion-confirmation: "true"
```

For more information about two data center disaster recovery upgrade, see Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.5.

i. Save and close the CR to apply your changes.
The response looks like the following example:

```
apiconnectcluster.apiconnect.ibm.com/prod configured
```

Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

j. Run the following command to verify that the upgrade is completed and the status of the top-level CR is `READY`:

```
oc get apiconnectcluster -n <APIC_namespace>
```

Important: If you need to restart the deployment, wait until all portal sites complete the upgrade.
After the portal subsystem upgrade is complete, each portal site is upgraded. You can monitor the site upgrade progress from the `MESSAGE` column in the `oc get ptl` output. You can still use the portal while sites are upgrading, although a maintenance page is shown for any sites that are being upgraded. When the site upgrades are complete, the `oc get ptl` output shows how many sites the portal is serving:

```
NAME     READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE              AGE
portal   3/3     Running   <version>        <version>            Serving 2 sites      22h
```

On two data center disaster recovery deployments, the sites are not upgraded until both data centers are upgraded.

Troubleshooting: If the upgrade appears to be stuck, showing the status of `Pending` for a long time, then check the management CR status for errors:

```
oc -n <namespace> get mgmt -o yaml
```

Refer to Troubleshooting upgrade on OpenShift, for known issues.

7. If you are using individual subsystem CRs: Start with the management subsystem, and update the management CR as follows:
   a. Edit the `ManagementCluster` CR:

```
oc edit ManagementCluster -n <mgmt_namespace>
```

   b. Update the `spec.version` property to the version you are upgrading to.
   c. If you are upgrading to a version of API Connect that requires a new license, update the `spec.license` property accordingly.
   For the list of licenses, see API Connect licenses.

   d. [This step is not applicable if you are upgrading from 10.0.8.0 or 10.0.8.1 to 10.0.8.2-ifix1] If you have a two data center disaster recovery installation, and are upgrading the warm-standby, then add the annotation:

```
apiconnect-operator/dr-warm-standby-upgrade-data-deletion-confirmation: "true"
```

   For more information about two data center disaster recovery upgrade, see Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.5.
   e. Save and close the CR to apply your changes.
   The response looks like the following example:

```
managementcluster.management.apiconnect.ibm.com/management edited
```

   Troubleshooting: If you see an error message when you attempt to save the CR, see Troubleshooting upgrade on OpenShift.

   f. Wait until the management subsystem upgrade is complete before you proceed to the next subsystem. Check the status of the upgrade with: `oc get ManagementCluster -n <mgmt_namespace>`, and wait until all pods are running at the new version. For example:

```
oc -n <mgmt_namespace> get ManagementCluster
NAME          READY   STATUS    VERSION    RECONCILED VERSION   AGE
management    18/18   Running   10.0.8.2-ifix1   10.0.8.2-ifix1-1281        97m
```

   Troubleshooting: If the upgrade appears to be stuck, showing the status of `Pending` for a long time, then check the management CR status for errors:

```
oc -n <namespace> get mgmt -o yaml
```

   Refer to Troubleshooting upgrade on OpenShift, for known issues.

   g. Repeat the process for the remaining subsystem CRs in your preferred order: `GatewayCluster`, `PortalCluster`, `AnalyticsCluster`.
   Important: In the `GatewayCluster` CR, delete any `template` or `dataPowerOverride` override sections. If the CR contains an override, then you cannot complete the upgrade.
   Note:

Upgrades to V10.0.8.0: By default the new PVC that is created for the analytics subsystem's local database backups is set to 150Gi. If you want to specify a larger size, then add the following to the CR **spec** section:

```
storage:
  backup:
    volumeClaimTemplate:
      storageClassName: <storage class>
      volumeSize: <size>
```

where:

- *<storage class>* is the same as used by your other analytics PVCs.
- *<size>* is the size. For example: **500Gi**. See Estimating storage requirements.

Important: If you need to restart the deployment, wait until all portal sites complete the upgrade.
After the portal subsystem upgrade is complete, each portal site is upgraded. You can monitor the site upgrade progress from the **MESSAGE** column in the **oc get ptl** output. You can still use the portal while sites are upgrading, although a maintenance page is shown for any sites that are being upgraded. When the site upgrades are complete, the **oc get ptl** output shows how many sites the portal is serving:

```
NAME     READY   STATUS    VERSION          RECONCILED VERSION   MESSAGE              AGE
portal   3/3     Running   <version>        <version>            Serving 2 sites      22h
```

On two data center disaster recovery deployments, the sites are not upgraded until both data centers are upgraded.

Troubleshooting: If the upgrade appears to be stuck, showing the status of **Pending** for a long time, then check the subsystem CR status for errors:

```
oc -n <namespace> get <subsystem cr> -o yaml
```

Refer to Troubleshooting upgrade on OpenShift, for known issues.

8. Upgrade your deployment to the latest version of OpenShift that your current release of API Connect supports.
   For more information, see Supported versions of OpenShift.

9. Optional: **If upgrading from 10.0.5.x or 10.0.7.0:** Provide a custom endpoint for the Consumer Catalog.
   Skip this step if you are upgrading from 10.0.8.0 or later.

   Beginning with version 10.0.8.0, API Connect includes the Consumer Catalog feature. If your deployment uses cert-manager, then during the upgrade from 10.0.5.x or 10.0.7.0, a new endpoint is added to the CR for the Custom Catalog. If you use the top-level APIConnectCluster CR, the new endpoint is added to the **spec.management** section. If you use individual CRs, the new endpoint is added to the management CR.

   The following definition is generated and automatically added to the CR during the upgrade, using a certificate from cert-manager:

   ```
   consumerCatalogEndpoint:
     annotations:
       cert-manager.io/issuer: ingress-issuer
     hosts:
     - name: consumer-catalog.<domain>
       secretName: <name>-consumer-catalog-endpoint
   ```

   a. Make the following optional changes to the endpoint definition in the CR:
      - Change the **name** to a host name of your own choosing.
      - Specify a custom cert-manager certificate.
   b. Run the following command to save and apply the CR: **wq**

10. Switch from deprecated deployment profiles.
    If you have a top-level CR installation, and were using the **n3xc16.m48** or **n3xc12.m40** deployment profiles, then switch to the new replacement profiles **n3xc16.m64** or **n3xc12.m56**. For information about switching profiles, see Changing deployment profiles on OpenShift top-level CR.

    If you are using individual subsystem CRs, and your analytics subsystem uses the **n3xc4.m16** profile, then update the profile in your analytics CR to **n3xc4.m32**. For information about switching profiles, see Changing deployment profiles on Kubernetes and OpenShift

What to do next

Update your toolkit CLI by downloading it from Fix Central or from the Cloud Manager UI. For more information, see Installing the toolkit.

Troubleshooting upgrade on OpenShift

Review the following troubleshooting tips if you encounter a problem during API Connect upgrade on OpenShift, including as a component of IBM Cloud Pak for Integration (CP4I).

Subsystem is stuck in `Pending` state with a reason of `PreUpgradeCheckInProgress`

Before the subsystem microservices are upgraded, the operator triggers a set of pre-upgrade checks that must pass for the upgrade to proceed. If one or more of the checks fail, the subsystem status remains in **Pending** state with a reason of **PreUpgradeCheckInProgress**. Check the status condition of the subsystem CR to confirm the pre-upgrade check failed. The **status.PreUpgradeCheck** property contains a summary of the failed checks. Full logs for the checks that are carried out can be viewed in the **ConfigMap** referenced in the **status.PreUpgradeCheck** property. The pre-upgrade checks automatically retry until they successfully pass. If you are unable to rectify the problem that causes a check to fail, then open an IBM support case.

Incorrect `productVersion` of gateway pods after upgrade

When you upgrade on OpenShift, the rolling update might fail to start on gateway operand pods due to a gateway peering issue, so that the **productVersion** of the gateway pods is incorrect even though the reconciled version on the gateway CR displays correctly. This problem happens when there are multiple primary pods for

gateway peering, and some of the peering pods are assigned to each primary. There can be only one primary pod for gateway-peering; the existence of multiple primaries prevents the upgrade from completing.

Verify that you have a gateway-peering issue with multiple primaries, and then resolve the issue by assigning a single primary for all gateway-peering pods. Complete the following steps:

1. Determine whether multiple primary pods are causing the problem:
   a. Run one of the following commands to check the `productVersion` of each gateway pod.

      ```
      oc get pods -n apic_namespace <gateway_pods> -o yaml | yq .metadata.annotations.productVersion
      ```

      or

      ```
      oc get pods -n apic_namespace <gateway_pods> -o custom-columns="productVersion:.metadata.annotations.productVersion"
      ```

      where:
      - *apic_namespace* is the namespace where API Connect is installed
      - *<gateway_pods>* is a space-delimited list of the names of your gateway peering pods

   b. Verify that the target version of API Connect supports the `productVersion`.
      For information about supported versions of DataPower Gateway, see
      tapic_upgrade_OpenShift_consider.html#tapic_upgrade_OpenShift_consider__gwy_versions.

   c. If any pod returns an incorrect value for the `productVersion`, check the DataPower operator logs for peering issues; look for messages similar to the following example:

      ```
      "level":"error","ts":"2023-10-20T16:31:47.824751077Z","logger":"controllers.DataPowerRollout","msg":"Unable to check

      10.254.20.175:true]","stacktrace":"github.ibm.com/datapower/datapower-
      operator/internal/controllers/datapowerrollout/gatewaypeering.
      (*GatewayPeeringPrimariesRolloutManager).isPrimary\n\t/home/jenkins/agent/workspace/datapower-
      operator_build_v1.6/internal/controllers/datapowerrollout/gatewaypeering/gatewaypeering.go:284\ngithub.ibm.com/datapo
      wer/datapower-operator/internal/controllers/datapowerrollout/gatewaypeering.
      (*GatewayPeeringPrimariesRolloutManager).IsPrimaryByPodName\n\t/home/jenkins/agent/workspace/datapower-
      operator_build_v1.6/internal/controllers/datapowerrollout/gatewaypeering/gatewaypeering.go:320\ngithub.ibm.com/datapo
      wer/datapower-operator/internal/controllers/datapowerrollout.
      (*DataPowerRolloutUpdater).mainWork\n\t/home/jenkins/agent/workspace/datapower-
      operator_build_v1.6/internal/controllers/datapowerrollout/workers.go:105"}
      ```

   If you confirmed that gateway-peering (multiple primaries) is the issue, complete the following steps to resolve the issue.

2. Attach to a gateway pod:
   a. Run the following command to get a list of gateway pods:

      ```
      oc get pods -l app.kubernetes.io/managed-by=datapower-operator
      ```

      The response looks like the following example:

      ```
      NAME                                                  READY   STATUS    RESTARTS   AGE
      datapower-operator-conversion-webhook-585d95cf87-mktrv   1/1     Running   0          2d22h
      datapower-operator-f4d8fbd85-5xt47                    1/1     Running   0          2d22h
      production-gw-0                                       1/1     Running   0          2d22h
      production-gw-1                                       1/1     Running   0          2d22h
      production-gw-2                                       1/1     Running   0          2d22h
      ```

   b. Select a pod from the list and run the following command to attach to it using the NAME:

      ```
      oc -n ns attach -it <pod_NAME> -c datapower
      ```

3. Select the new primary:
   a. Run the following commands to switch to the API Connect configuration:

      ```
      config; switch apiconnect
      ```

b. Run the following command to show the current peering status:

```
show gateway-peering-status
```

Example response:

```
Address      Name              Pending Offset     Link Primary Service port Monitor port Priority
------------ ----------------- ------- ---------- ---- ------- ------------ ------------ --------
10.254.12.45 api-probe         0       19114431   ok   no      16382        26382        2
10.254.12.45 gwd               0       1589848370 ok   no      16380        26380        2

10.254.28.61 tms-external      0       19117965   ok   yes     16385        26385        1
10.254.36.32 api-probe         0       19114739   ok   yes     16382        26382        3
10.254.36.32 gwd               0       1589848370 ok   no      16380        26380        3
10.254.36.32 rate-limit        0       19148496   ok   no      16383        26383        3
10.254.36.32 ratelimit-module  0       19117538   ok   no      16386        26386        3
10.254.36.32 subs              0       26840742   ok   no      16384        26384        3
10.254.36.32 tms               0       19115634   ok   no      16381        26381        3
10.254.36.32 tms-external      0       19116159   ok   no      16385        26385        3
```

c. Take note of the IP address that has the most primary **yes** options; this IP address will be the new primary for all **functions** involved in gateway peering. In this example, **10.254.28.61** is the primary for the largest number of **functions**; however **api-probe** is not primary on this pod. In the following steps, set **api-probe** as primary on this pod.

4. For every function that needs the primary changed, attach to the primary pod and set the function to primary:
   a. Log out of the current pod by pressing Ctrl+P, and then pressing Ctrl+Q.
   b. Run the following command to attach to a pod that needs its primary updated:

```
oc -n ns attach -it <IP_of_pod> -c datapower
```

   c. Run the following command to switch to the API Connect configuration:

```
config; switch apiconnect
```

   d. Run the following command to show the current peering status:

```
show gateway-peering-status
```

   Verify that the function is set to the wrong primary IP and requires updating (in the example, **api-probe** requires updating).

   e. Run the following command to change the primary for the function:

```
gateway-peering-switch-primary <function>
```

   For example:

```
gateway-peering-switch-primary api-probe
```

   f. Repeat this process for every function that needs its primary updated.
5. Verify that all functions are now primary on the same IP address by running the following command:

```
show gateway-peering-status
```

6. Log out of the gateway pod (Ctrl+P, then Ctrl+Q).

Upgrade fails with an error message about a missing cert-manager

Beginning in API Connect V10.0.7.0, it is recommended to use the cert-manager operator for Red Hat OpenShift. If you did not install Red Hat OpenShift cert-manager operator during the upgrade, the upgrade fails with the following error message from the **ibm-apiconnect** pod:

```
cert-manager is required but not installed. Please install a cert-manager operator such as [cert-manager Operator for Red Hat OpenShift]. APIC instance being upgraded
```

Resolve the issue by completing the following steps:

1. Install the cert-manager operator for Red Hat OpenShift:
   a. Log in to the OpenShift Container Platform web console.
   b. Click Operators > OperatorHub.
   c. In the filter box, type: **cert-manager Operator for Red Hat OpenShift**.
   d. Select cert-manager Operator for Red Hat OpenShift and click Install.
   e. On the Install Operator page, complete the following steps:
      i. Update the Update channel if needed. The channel defaults to **stable-v1**, which installs the latest stable release of the cert-manager Operator for Red Hat OpenShift.
      ii. Select the Installed Namespace for the operator.
      The default operator namespace is **cert-manager-operator**; if that namespace doesn't exist, it is created for you.

iii. Select an Update approval strategy:
- Automatic: allow Operator Lifecycle Manager (OLM) to automatically update the operator when a new version is available.
- Manual: require a user with the appropriate credentials to approve all operator updates.

iv. Click Install.

2. Verify the new cert-manager installation by completing the following steps:
   a. Click Operators > Installed Operators.
   b. Verify that `cert-manager Operator for Red Hat OpenShift` is listed with a Status of `Succeeded` in the `cert-manager-operator` namespace.
   c. Verify that cert-manager pods are up and running with the following command:

```
oc get pods -n cert-manager
```

   For a successful installation, the response looks like the following example:

```
NAME                                       READY   STATUS    RESTARTS   AGE
cert-manager-bd7fbb9fc-wvbbt               1/1     Running   0          3m39s
cert-manager-cainjector-56cc5f9868-7g9z7   1/1     Running   0          4m5s
cert-manager-webhook-d4f79d7f7-9dg9w       1/1     Running   0          4m9s
```

3. Remove the obsolete IBM cert-manager operator by running the following command:

```
oc delete certmanagers.operator.ibm.com default
```

DataPower operator pod stuck waiting for lock removal

If you see messages in the `datapower-operator` pod log that indicate that the pod is waiting for a lock to be removed:

```
{"level":"info","ts":"2021-03-08T19:29:53.432Z","logger":"leader","msg":"Not the leader. Waiting."}
{"level":"info","ts":"2021-03-08T19:29:57.971Z","logger":"leader","msg":"Leader pod has been deleted, waiting for garbage collection to remove the lock."}
```

The DataPower operator cannot be upgraded until this problem is resolved, see: DataPower operator documentation.

You see the `denied: insufficient scope` error during an air-gapped deployment

Problem: You encounter the `denied: insufficient scope` message while mirroring images during an air-gapped installation or upgrade.

Reason: This error occurs when a problem is encountered with the entitlement key that is used for obtaining images.

Solution: Obtain a new entitlement key by completing the following steps:

1. Log in to the IBM Container Library.
2. In the Container software library, select Get entitlement key.
3. After the Access your container software heading, click Copy key.
4. Copy the key to a safe location.

Apiconnect operator pod fails

Problem: During installation (or upgrade), the `apiconnect` operator fails with the following message:

```
panic: unable to build API support: unable to get Group and Resources: unable to retrieve the complete list of server APIs:
packages.operators.coreos.com/v1: the server is currently unable to handle the request

goroutine 1 [running]:
github.ibm.com/velox/apiconnect-operator/operator-utils/v2/apiversions.GetAPISupport(0x0)
        operator-utils/v2/apiversions/api-versions.go:89 +0x1e5
main.main()
        ibm-apiconnect/cmd/manager/main.go:188 +0x4ee
```

Additional symptoms:

- Apiconnect operator is in crash loopback status
- Kube `apiserver` pods log the following information:

```
E1122 18:02:07.853093 18 available_controller.go:437] v1.packages.operators.coreos.com failed with:
 failing or missing response from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1:
 bad status from https://10.128.0.3:5443/apis/packages.operators.coreos.com/v1: 401
```

- The IP logged here belongs to the *package server* pod present in the `openshift-operator-lifecycle-manager` namespace
- Package server pods log the following error message: `/apis/packages.operators.coreos.com/v1 API call is being rejected with 401 issue`.

```
E1122 18:10:25.614179 1 authentication.go:53] Unable to authenticate the request due to an error: x509:
certificate signed by unknown authority I1122 18:10:25.614224 1 httplog.go:90]
verb="GET" URI="/apis/packages.operators.coreos.com/v1" latency=161.243µs resp=401
UserAgent="Go-http-client/2.0" srcIP="10.128.0.1:41370":
```

- The problem is intermittent

Solution:

- If you find the exact symptoms as described, the solution is to delete package server pods in the `openshift-operator-lifecycle-manager` namespace.
- New package server pods log the `200 Success` message for the same API call.

Unexpected behavior in Cloud Manager and API Manager UIs after upgrade

Stale browser cache issues can cause problems after an upgrade. To remedy this problem, clear your browser cache, and open a new browser window.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.7 or later

How to upgrade an API Connect V10.0.7 (or later) two data center disaster recovery (DR) deployment on Kubernetes and OpenShift.

To upgrade API Connect in a 2DCDR deployment, use the upgrade instructions for your platform, but with the extra considerations and steps documented in this topic.

- Upgrading on Kubernetes.
- Upgrading on OpenShift and Cloud Pak for Integration.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **`kubectl`** command. On OpenShift, use the equivalent **`oc`** command in its place.

Before you begin

- Verify that API Connect is running in both data centers and that replication is working: Verifying replication between data centers.
- Check that you have recent backups of management and portal subsystems: Backup and restore requirements for a 2DCDR deployment.

Key points applicable to both management and portal subsystems

- Your API Connect deployments must be upgraded to the same API Connect release, down to the interim fix level.
- Both data centers must be upgraded in the same maintenance window.
- Upgrade steps might result in an update to the **`ingress-ca`** X.509 certificate. Extra steps must be taken at various points in the upgrade process to ensure that the **`ingress-ca`** secret in both data centers contains the same **`ingress-ca`** X.509 certificate.

Note: If you are not using cert-manager and you customized your certificates, the **`ingress-ca`** certificate might have a different name. Ensure that the CA certificate that is used by both data centers is the same during all stages of the upgrade.

Steps for management upgrades

1. Upgrade the warm-standby data center first.
   Follow the upgrade steps for your platform:
   - Upgrading API Connect on Kubernetes.
   - Upgrading API Connect on OpenShift.

   Check the status of the warm-standby upgrade and run the following commands:
   a. Get the management CR summary:

   ```
   kubectl get mgmt -A
   ```

   returns:

   ```
   NAMESPACE   NAME    READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
   AGE
   apic        mgt     5/6     Pending   10.0.8.0   10.0.8.0-0           Some services are not ready - see status
   condition for details. HA status Ready - see HAStatus in CR for details   48m

   k get mgmt m2 -n nihar -o json | jq -r '.status.conditions[] | select(.status=="True")'
   {
     "lastTransitionTime": "2024-05-14T00:26:25Z",
     "message": "Not all services are ready, next pending services: apim-lur-schema-data-check. Please upgrade Active to
   10.0.8.0 to match warm standby's version. HA status Ready - see HAStatus in CR for details",
     "reason": "na",
     "status": "True",
     "type": "Pending"
   }
   ```

   b. Get the management CR status:

   ```
   kubectl get mgmt <mgmt CR name> -o json | jq -r '.status.conditions[] | select(.status=="True")'
   ```

   returns:

   ```
   {
     "lastTransitionTime": "2024-05-14T00:26:25Z",
     "message": "Not all services are ready, next pending services: apim-lur-schema-data-check. Please upgrade Active to
   10.0.8.0 to match warm standby's version. HA status Ready - see HAStatus in CR for details",
     "reason": "na",
     "status": "True",
     "type": "Pending"
   }
   ```

   Note: The warm-standby may not remain in a pending state in all cases during an upgrade. When there are no schema changes between the source and target versions, warm-standby will move to a ready state, which is an acceptable condition. If schema changes are present, warm-standby will remain in a pending state until the active system is upgraded.

2. Verify that both data centers have the same **`ingress-ca`** X.509 certificate in their **`ingress-ca`** secret. Run the following command in both data centers and check that the output is the same:

```
openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d)
```

if you do not have the `openssl` command available, you can instead run only the `kubectl` part, which produces a larger output:

```
kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
```

if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.

3. Upgrade the active data center, following the steps for your platform:
   - Upgrading API Connect on Kubernetes.
   - Upgrading API Connect on OpenShift.

Steps for portal upgrades

1. Verify that both data centers have the same `ingress-ca` X.509 certificate in their `ingress-ca` secret. Run the following command in both data centers and check that the output is the same:

   ```
   openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d)
   ```

   if you do not have the `openssl` command available, you can instead run only the `kubectl` part, which produces a larger output:

   ```
   kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
   ```

   if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.
2. Start the upgrade of your warm-standby data center by following the upgrade documentation for your platform. Stop at the point where the portal CR is updated with the new API Connect version.
3. Verify that both data centers still have the same `ingress-ca` X.509 certificate, repeating step 1. If they are different, then follow these steps: Synchronizing the ingress-ca X.509 certificate across data centers.
4. Continue the upgrade of your warm-standby data center by updating the portal subsystem CR, following the remaining upgrade steps for your platform. Do not wait for the warm-standby to reach READY state before starting the upgrade on the active data center (in certain circumstances the warm-standby portal does not reach READY state until the active data center is upgraded).
5. Start the upgrade of your active data center by following the upgrade documentation for your platform. Stop at the point where the portal CR is updated with the new API Connect version.
6. Verify that both data centers still have the same `ingress-ca` X.509 certificate, repeating step 1. If they are different, then follow these steps: Synchronizing the ingress-ca X.509 certificate across data centers.
7. Upgrade the portal subsystem in your active data center by updating the portal subsystem CR, following the remaining upgrade steps for your platform.

How to upgrade when one data center is down

If API Connect is still running on the failed data center, follow the steps that are documented previously to upgrade both data centers before you bring the failed data center back online.

If the failed data center is expected to be down for a long time, you can convert the active data center to a stand-alone data center by following these steps: Removing a two data center deployment, but note the following points:

1. Ensure that the network links to the failed data center are removed.
2. Ensure that the failed data center is set to warm-standby in the `multiSiteHA` section. Do not proceed to the next step until the data center completes the transition to warm-standby. View the status of the management and portal CRs to confirm that `HA Mode` reports "passive".
3. Remove the `multiSiteHA` section from failed data center, and verify that the failed data center resets itself to become an empty stand-alone API Connect deployment (all data is deleted).
4. Before you restore the network links between the data centers, do the following operations:
   - Upgrade API Connect on the failed data center to the same version as the active.
   - Add the `multiSiteHA` sections to both data centers, setting the failed data center to be warm-standby.
     Important: Do not set the failed data center to be active in the `multiSiteHA` section because it results in an overwrite of the data on your working data center with the empty database of your failed data center.

Upgrading a 2DCDR deployment on Kubernetes and OpenShift from V10.0.5

How to upgrade a two data center disaster recovery deployment to V10.0.8 from V10.0.5 on Kubernetes and OpenShift.

To upgrade API Connect in a 2DCDR deployment, use the upgrade instructions for your platform, but with the extra considerations and steps documented in this topic.

- Upgrading on Kubernetes.
- Upgrading on OpenShift and Cloud Pak for Integration.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Before you begin

- Verify that API Connect is running in both data centers and that replication is working: Verifying replication between data centers.
- Check that you have recent backups of management and portal subsystems: Backup and restore requirements for a 2DCDR deployment.
- If you have a top-level CR deployment, and your portal and management warm-standby subsystems are not in the same data center, then complete an operational failover of either the management or portal subsystems so that they are both warm-standby in the same data center. See Failing over to the warm-standby.

Key points applicable to both management and portal subsystems

- Your API Connect deployments must be upgraded to the same API Connect release, down to the interim fix level.

- Both data centers must be upgraded in the same maintenance window.
- Upgrade steps might result in an update to the `ingress-ca` X.509 certificate. Extra steps must be taken at various points in the upgrade process to ensure that the `ingress-ca` secret in both data centers contains the same `ingress-ca` X.509 certificate.

Note: If you are not using cert-manager and you customized your certificates, the `ingress-ca` certificate might have a different name. Ensure that the CA certificate that is used by both data centers is the same during all stages of the upgrade.

Upgrading to V10.0.8: Steps for management upgrades

1. Upgrade the warm-standby data center first.
   Follow the upgrade steps for your platform:
   - Upgrading API Connect on Kubernetes.
   - Upgrading API Connect on OpenShift.

   When the warm-standby upgrade is complete, the warm-standby management CR reports an HA status error:

   ```
   kubectl get mgmt -A
   ```

   returns:

   ```
   NAMESPACE   NAME   READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
   AGE
   ns1         m2     2/19    Blocked   10.0.8.1   10.0.5.5-6227        HA status Error - see HAStatus in CR for details
   83m
   ```

   Confirm the blocked status with the following command:

   ```
   kubectl get mgmt <management CR name> -o json| jq -r '.status.conditions[] | select(.status=="True")
   ```

   returns:

   ```
   {
     "lastTransitionTime": "2024-05-21T16:05:34Z",
     "message": "HA status Error - see HAStatus in CR for details",
     "reason": "na",
     "status": "True",
     "type": "Blocked"
   }
   ```

   Check the HA status with the following command:

   ```
   kubectl get mgmt <management CR name> -o json | jq -r '.status.haStatus[] | select(.status=="True")'
   ```

   returns:

   ```
   {
     "lastTransitionTime": "2024-05-21T16:05:34Z",
     "message": "Remote HAMode is Empty (Not received from peer). Expected it to be in either active or setup complete
   phase",
     "reason": "na",
     "status": "True",
     "type": "Error"
   }
   ```

   Do not proceed until the warm-standby reports this status.

2. Verify that both data centers have the same `ingress-ca` X.509 certificate in their `ingress-ca` secret. Run the following command in both data centers and check that the output is the same:

   ```
   openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" |
   awk '{print $2}' | base64 -d)
   ```

   if you do not have the `openssl` command available, you can instead run only the `kubectl` part, which produces a larger output:

   ```
   kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
   ```

   if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.
3. Upgrade the active data center, following the steps for your platform:
   - Upgrading API Connect on Kubernetes.
   - Upgrading API Connect on OpenShift.

Steps for portal upgrade

1. Verify that both data centers have the same `ingress-ca` X.509 certificate in their `ingress-ca` secret. Run the following command in both data centers and check that the output is the same:

   ```
   openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" |
   awk '{print $2}' | base64 -d)
   ```

   if you do not have the `openssl` command available, you can instead run only the `kubectl` part, which produces a larger output:

   ```
   kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
   ```

   if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.
2. Start the upgrade of your warm-standby data center by following the upgrade documentation for your platform. Stop at the point where the portal CR is updated with the new API Connect version.
3. Verify that both data centers still have the same `ingress-ca` X.509 certificate, repeating step 1. If they are different, then follow these steps: Synchronizing the ingress-ca X.509 certificate across data centers.
4. Complete the upgrade of your warm-standby data center by updating the portal subsystem CR, following the remaining upgrade steps for your platform. Do not wait for the warm-standby to reach READY state before starting the upgrade on the active data center (in certain circumstances the warm-standby portal does not reach

READY state until the active data center is upgraded).
For example, let's assume that both DCs have the portal cluster (PTL) CR in Warning state with a message that says, "*Full file synchronization running*". You can move both DCs from the Warning state by upgrading the Active state.

5. Start the upgrade of your active data center by following the upgrade documentation for your platform. Stop at the point where the portal CR is updated with the new API Connect version.
6. Verify that both data centers still have the same **`ingress-ca`** X.509 certificate, repeating step 1. If they are different, then follow these steps: Synchronizing the ingress-ca X.509 certificate across data centers.
7. Upgrade the portal subsystem in your active data center by updating the portal subsystem CR, following the remaining upgrade steps for your platform.

How to upgrade when one data center is down

If API Connect is still running on the failed data center, follow the steps that are documented previously to upgrade both data centers before you bring the failed data center back online.

If the failed data center is expected to be down for a long time, you can convert the active data center to a stand-alone data center by following these steps: Removing a two data center deployment, but note the following points:

1. Ensure that the network links to the failed data center are removed.
2. Ensure that the failed data center is set to warm-standby in the **`multiSiteHA`** section. Do not proceed to the next step until the data center completes the transition to warm-standby. View the status of the management and portal CRs to confirm that **`HA Mode`** reports "passive".
3. Remove the **`multiSiteHA`** section from failed data center, and verify that the failed data center resets itself to become an empty stand-alone API Connect deployment (all data is deleted).
4. Before you restore the network links between the data centers, do the following operations:
   - Upgrade API Connect on the failed data center to the same version as the active.
   - Add the **`multiSiteHA`** sections to both data centers, setting the failed data center to be warm-standby.
     Important: Do not set the failed data center to be active in the **`multiSiteHA`** section because it results in an overwrite of the data on your working data center with the empty database of your failed data center.

Related tasks

- Installing a two data center deployment on Kubernetes

Upgrading a 2DCDR deployment on Cloud Pak for Integration from V10.0.7 or later

How to upgrade from an API Connect V10.0.7 (or later) two data center disaster recovery (DR) deployment on Cloud Pak for Integration.

To upgrade a Cloud Pak for Integration deployment of API Connect in a 2DCDR deployment, use the Cloud Pak for Integration upgrade instructions Upgrading on OpenShift and Cloud Pak for Integration, but with the extra considerations and steps documented in this topic.

Before you begin

- Verify that API Connect is running in both data centers and that replication is working: Verifying replication between data centers.
- Check that you have recent backups of management and portal subsystems: Backup and restore requirements for a 2DCDR deployment.
- If you have a top-level CR deployment, and your portal and management warm-standby subsystems are not in the same data center, then complete an operational failover of either the management or portal subsystems so that they are both warm-standby in the same data center. See Failing over to the warm-standby.

Key points applicable to both management and portal subsystems

- Your API Connect deployments must be upgraded to the same API Connect release, down to the interim fix level.
- Both data centers must be upgraded in the same maintenance window.
- Upgrade steps might result in an update to the **`ingress-ca`** X.509 certificate. Extra steps must be taken at various points in the upgrade process to ensure that the **`ingress-ca`** secret in both data centers contains the same **`ingress-ca`** X.509 certificate.

2DCDR upgrade steps for Cloud Pak for Integration

In Cloud Pak for Integration, the **`apiconnectcluster`** CR (also known as the top-level CR) manages the management and portal subsystems. When the **`apiconnectcluster`** CR is updated with the new API Connect version, all the subsystems are updated automatically. Follow the upgrade process for Cloud Pak for Integration, review Upgrading on OpenShift and Cloud Pak for Integration, along with the following steps.

1. Verify that both data centers have the same 2DCDR mode for both management and portal subsystems. For example, in DC1, both management and portal subsystems are active, and in DC2, both are warm-standby. If necessary, complete a failover of one of the subsystems so that management and portal have the same mode in the same data centers: Failing over to the warm-standby.
2. Verify that both data centers have the same **`ingress-ca`** X.509 certificate in their **`<apic instance-name>-ingress-ca`** secret. Run the following command in both data centers and check that the output is the same:

   ```
   openssl x509 -noout -fingerprint -sha256 -in <(oc get secret <apic instance-name>-ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d)
   ```

   if you do not have the **`openssl`** command available, you can instead run only the **`oc`** part, which produces a larger output:

```
oc get secret <apic instance-name>-ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
```

if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.

3. Start the upgrade of your warm-standby data center.
   Follow the upgrade documentation for the API Management capability in https://www.ibm.com/docs/en/cloud-paks/cp-integration. Stop at the point after the API Connect and DataPower operators are updated but before the operands are updated.
4. Repeat step 1 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
5. Complete the upgrade of your warm-standby data center, updating the operands as described in the Cloud Pak for Integration documentation.
6. Check the status of your APIConnectCluster and management CRs and do not proceed until the output of the following commands matches what is shown below:
   a. Get the APIConnectCluster CR summary:

   ```
   oc get apiconnectcluster <apic CR name>
   ```

   returns:

   ```
   NAME          READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
   AGE
   apic          4/5     Pending   10.0.8.0   10.0.7.0-5560        API Connect cluster upgrade in progress - see status
   conditions for details   63m
   ```

   b. Check the cluster status:

   ```
   oc get apiconnectcluster <apic CR name> -o json | jq -r '.status.conditions[] | select(.status=="True")'
   ```

   returns:

   ```
   {
     "lastTransitionTime": "2024-05-17T21:05:15Z",
     "message": "APIC instance being upgraded. Not all services are ready, pending services: management",
     "reason": "Upgrading",
     "status": "True",
     "type": "Pending"
   }
   ```

   c. Check the management subsystem status:

   ```
   oc get mgmt <mgmt CR name> -o json | jq -r '.status.conditions[] | select(.status=="True")'
   ```

   returns:

   ```
   {
     "lastTransitionTime": "2024-05-17T21:10:06Z",
     "message": "Not all services are ready, next pending services: apim-lur-schema-data-check. Please upgrade Active to
   10.0.8.0 to match warm standby's version. HA status Ready - see HAStatus in CR for details",
     "reason": "na",
     "status": "True",
     "type": "Pending"
   }
   ```

7. Repeat step 1 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
8. Start the upgrade of your active data center by following the upgrade documentation for the API Management capability in https://www.ibm.com/docs/en/cloud-paks/cp-integration. Stop at the point after the API Connect and DataPower operators are updated but before the operands are updated.
9. Repeat step 1 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
10. Complete the upgrade of the active data center, updating the operands as described in the Cloud Pak for Integration documentation.

How to upgrade when one data center is down

If API Connect is still running on the failed data center, follow the steps that are documented previously to upgrade both data centers before you bring the failed data center back online.

If the failed data center is expected to be down for a long time, you can convert the active data center to a stand-alone data center by following these steps: Removing a two data center deployment, but note the following points:

1. Ensure that the network links to the failed data center are removed.
2. Ensure that the failed data center is set to warm-standby in the **multiSiteHA** section. Do not proceed to the next step until the data center completes the transition to warm-standby. View the status of the management and portal CRs to confirm that **HA Mode** reports "passive".
3. Remove the **multiSiteHA** section from failed data center, and verify that the failed data center resets itself to become an empty stand-alone API Connect deployment (all data is deleted).
4. Before you restore the network links between the data centers, do the following operations:
   - Upgrade API Connect on the failed data center to the same version as the active.
   - Add the **multiSiteHA** sections to both data centers, setting the failed data center to be warm-standby.
     Important: Do not set the failed data center to be active in the **multiSiteHA** section because it results in an overwrite of the data on your working data center with the empty database of your failed data center.

Upgrading a 2DCDR deployment on Cloud Pak for Integration from V10.0.5

How to upgrade from an API Connect V10.0.5 two data center disaster recovery (DR) deployment on Cloud Pak for Integration.

To upgrade a Cloud Pak for Integration deployment of API Connect in a 2DCDR deployment, use the Cloud Pak for Integration upgrade instructions Upgrading on OpenShift and Cloud Pak for Integration, but with the extra considerations and steps documented in this topic.

Before you begin

- Verify that API Connect is running in both data centers and that replication is working: Verifying replication between data centers.
- Check that you have recent backups of management and portal subsystems: Backup and restore requirements for a 2DCDR deployment.
- If you have a top-level CR deployment, and your portal and management warm-standby subsystems are not in the same data center, then complete an operational failover of either the management or portal subsystems so that they are both warm-standby in the same data center. See Failing over to the warm-standby.

Key points applicable to both management and portal subsystems

- Your API Connect deployments must be upgraded to the same API Connect release, down to the interim fix level.
- Both data centers must be upgraded in the same maintenance window.
- Upgrade steps might result in an update to the **ingress-ca** X.509 certificate. Extra steps must be taken at various points in the upgrade process to ensure that the **ingress-ca** secret in both data centers contains the same **ingress-ca** X.509 certificate.

V10.0.5 to V10.0.8 2DCDR upgrade steps for Cloud Pak for Integration

In Cloud Pak for Integration, the **apiconnectcluster** CR (also known as the top-level CR) manages the management and portal subsystems. When the **apiconnectcluster** CR is updated with the new API Connect version, all the subsystems are updated automatically. Follow the upgrade process for Cloud Pak for Integration, review Upgrading on OpenShift and Cloud Pak for Integration, along with the following steps.

1. Verify that both data centers have the same 2DCDR mode for both management and portal subsystems. For example, in DC1, both management and portal subsystems are active, and in DC2, both are warm-standby. If necessary, complete a failover of one of the subsystems so that management and portal have the same mode in the same data centers: Failing over to the warm-standby.
2. Verify that both data centers have the same **ingress-ca** X.509 certificate in their ***<apic instance-name>*-ingress-ca** secret. Run the following command in both data centers and check that the output is the same:

   ```
   openssl x509 -noout -fingerprint -sha256 -in <(oc get secret <apic instance-name>-ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d)
   ```

   if you do not have the **openssl** command available, you can instead run only the **oc** part, which produces a larger output:

   ```
   oc get secret <apic instance-name>-ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
   ```

   if the outputs are different, follow these steps to synchronize the certificates: Synchronizing the ingress-ca X.509 certificate across data centers.
3. Start the upgrade of your warm-standby data center.
   Follow the upgrade documentation for the API Management capability in https://www.ibm.com/docs/en/cloud-paks/cp-integration. Stop at the point after the API Connect and DataPower operators are updated but before the operands are updated.
4. Repeat step 2 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
5. Complete the upgrade of your warm-standby data center, updating the operands as described in the Cloud Pak for Integration documentation.
6. Check the state of your APIConnectCluster CR:
   a. Check the cluster status:

      ```
      oc get apiconnectcluster <apic CR name> -o json | jq -r '.status.conditions[] | select(.status=="True")'
      ```

      returns:

      ```
      {
        "lastTransitionTime": "2024-05-17T21:05:15Z",
        "message": "APIC instance being upgraded. Not all services are ready, pending services: management",
        "reason": "Upgrading",
        "status": "True",
        "type": "Pending"
      }
      ```

   b. Check the management subsystem status:

      ```
      oc get mgmt <mgmt CR name> -o json | jq -r '.status.conditions[] | select(.status=="True")'
      ```

      returns:

      ```
      {
        "lastTransitionTime": "2024-05-21T16:05:34Z",
        "message": "HA status Error - see HAStatus in CR for details",
        "reason": "na",
        "status": "True",
        "type": "Blocked"
      }
      ```

   c. Check the management subsystem 2DCDR status:

      ```
      oc get mgmt <mgmt CR name> -o json | jq -r '.status.haStatus[] | select(.status=="True")'
      ```

      returns:

      ```
      {
        "lastTransitionTime": "2024-05-21T16:05:34Z",
        "message": "Remote HAMode is Empty (Not received from peer). Expected it to be in either active or setup complete phase",
        "reason": "na",
        "status": "True",
        "type": "Error"
      }
      ```

7. Repeat step 2 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
8. Start the upgrade of your active data center by following the upgrade documentation for the API Management capability in https://www.ibm.com/docs/en/cloud-paks/cp-integration. Stop at the point after the API Connect and DataPower operators are updated but before the operands are updated.
9. Repeat step 2 to verify that the **ingress-ca** X.509 certificates are still the same in both data centers.
10. Complete the upgrade of the active data center, updating the operands as described in the Cloud Pak for Integration documentation.
11. If the management CR has successfully reconciled to the new version:

```
NAME              READY   STATUS    VERSION         RECONCILED VERSION   MESSAGE
AGE
production-mgmt   6/6     Running   10.0.8.1-1087   10.0.8.1-1087        Management is ready. HA status Ready - see
HAStatus in CR for details 46h
```

but the portal CR spec has not been updated to the new version:

```
NAME             READY   STATUS    VERSION         RECONCILED VERSION   MESSAGE                              AGE
production-ptl   7/7     Warning   10.0.5.7        10.0.5.7-300         Full file synchronization running    46h
```

Then you must manually set the **spec.version** property in the portal CR to the new version to proceed with the upgrade. This issue can occur due to incompatibilities in the file synchronization specification between the old and new portal web (www) pods.

12. 2DCDR installations on Cloud Pak for Integration before V10.0.7 required the creation of a custom endpoint for the management subsystem user-facing certificates. The custom endpoint is not required from V10.0.7 and later, so you can update your management subsystem endpoints.
In both data centers, edit your top-level CR:

```
oc edit apiconnectcluster
```

Add the following endpoint sections:

- **spec.management.cloudManagerEndpoint**
- **spec.management.apiManagerEndpoint**
- **spec.management.platformAPIEndpoint**
- **spec.management.consumerAPIEndpoint**
- **spec.management.consumerCatalogEndpoint**

For example:

```
    cloudManagerEndpoint:
      annotations:
        cert-manager.io/issuer: <APIConnectCluster CR name>-ingress-issuer
      hosts:
      - name: <cloudManagerEndpoint>
        secretName: <secret name>
```

where:

- *<APIConnectCluster CR name>* is the name of your APIConnectCluster CR. Run **oc get apiconnectcluster** to see this name.
- *<cloudManagerEndpoint>* is the new endpoint that you want to use for the Cloud Manager UI.
- *<secret name>* name for the secret that stores the TLS certificate for the endpoint. Set this value as follows according to the endpoint:
  - **platformAPIEndpoint**: *<APIConnectCluster CR name>*-mgmt-platform-api
  - **consumerAPIEndpoint**: *<APIConnectCluster CR name>*-mgmt-consumer-api
  - **cloudManagerEndpoint**: *<APIConnectCluster CR name>*-mgmt-admin
  - **apiManagerEndpoint**: *<APIConnectCluster CR name>*-mgmt-api-manager
  - **consumerCatalogEndpoint**: *<APIConnectCluster CR name>*-consumer-catalog

How to upgrade when one data center is down

If API Connect is still running on the failed data center, follow the steps that are documented previously to upgrade both data centers before you bring the failed data center back online.

If the failed data center is expected to be down for a long time, you can convert the active data center to a stand-alone data center by following these steps: Removing a two data center deployment, but note the following points:

1. Ensure that the network links to the failed data center are removed.
2. Ensure that the failed data center is set to warm-standby in the **multiSiteHA** section. Do not proceed to the next step until the data center completes the transition to warm-standby. View the status of the management and portal CRs to confirm that **HA Mode** reports "passive".
3. Remove the **multiSiteHA** section from failed data center, and verify that the failed data center resets itself to become an empty stand-alone API Connect deployment (all data is deleted).
4. Before you restore the network links between the data centers, do the following operations:
   - Upgrade API Connect on the failed data center to the same version as the active.
   - Add the **multiSiteHA** sections to both data centers, setting the failed data center to be warm-standby.
     Important: Do not set the failed data center to be active in the **multiSiteHA** section because it results in an overwrite of the data on your working data center with the empty database of your failed data center.

Maintaining API Connect

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management on Kubernetes.

Note: When maintaining API Connect, do not use **kubectl exec** or **oc exec** commands to access API Connect pods unless advised by IBM.

- **Advanced configuration**
  You can optionally install and configure advanced features.
- **Backing up, restoring, and disaster recovery**
  Backup your API Connect subsystems, configure scheduled database backups, and recover from a disaster.
- **Maintaining a two data center deployment**
  How to maintain a two data center disaster recovery (DR) deployment on Kubernetes and OpenShift, including information about normal operation, failure handling, and recovery.
- **Renewing TLS certificates**
  Renew TLS certificates in your API Connect deployment.
- **Monitoring and health checks**
  Monitor your deployment and complete health checks on subsystems.

- **Logging**
  Configure logging for your deployment on Kubernetes.
- **Troubleshooting**
  Troubleshooting problems with your API Connect subsystems.

Advanced configuration

You can optionally install and configure advanced features.

See:

- **Installing License Service**
  License Service helps you assess whether your IBM® API Connect deployment in a Kubernetes environment is compliant with licensing requirements.
- **Installing the Automated API behavior testing application**
  Update the custom resource for installing IBM API Connect to deploy the Automated API behavior testing application on Kubernetes.
- **Installing the toolkit**
- **Customizing user-facing certificates**
  Convert a user-facing certificate that was generated by cert-manager to a custom certificate for an existing IBM API Connect deployment.
- **Changing deployment profiles on Kubernetes and OpenShift**
  You can change an API Connect installation to use different deployment profiles.
- **Changing deployment profiles on OpenShift top-level CR**
  You can change an API Connect top-level CR installation to use different profiles.
- **Changing the deployment profile on Cloud Pak for Integration**
  You can change an API Connect installation to use a different profile.
- **Replica override for microservices**
  Modify the replica count for microservices by using template overrides for Custom Resources.
- **Enabling Developer Portal feature flags on Kubernetes**
  Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.
- **Enabling Developer Portal feature flags on OpenShift and Cloud Pak for Integration**
  Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.
- **Enabling UI feature flags on Kubernetes**
  Use a template override to update the installation CR with settings that control UI features.
- **Enabling UI feature flags on OpenShift and Cloud Pak for Integration**
  Use a template override to update the installation CR with settings that control UI features.
- **Adding external annotation to routes and ingresses**
  You can add external annotations and labels to routes and ingresses.
- **Advanced configuration for the management subsystem**
  Specify advanced configuration for the management subsystem.
- **Advanced configuration for the analytics subsystem**
  Specify advanced configuration for the analytics subsystem on Kubernetes, OpenShift, or Cloud Pak for Integration.
- **Advanced configuration for the gateway subsystem**
  Specify advanced configuration for the gateway subsystem.
- **Advanced configuration for the portal subsystem**

Installing License Service

License Service helps you assess whether your IBM® API Connect deployment in a Kubernetes environment is compliant with licensing requirements.

About this task

License Service provides useful features for managing virtualized environments and measuring license utilization. License Service discovers the software that is installed in your infrastructure, helps you to analyze the consumption data, and allows you to generate audit reports. Each report provides you with different information about your infrastructure, for example the computer groups, software installations, and the content of your software catalog.

By default, every License Service audit report presents data from the previous 90 days. You can customize the type and amount of information that is displayed in a report by using filters, and save your personal settings for future use. You can also export the reports to .csv or pdf format, and schedule report emails so that specified recipients are notified when important events occur.

When you install API Connect, the **`license-use`** setting that is configured in the ibm-apiconnect operator CR (custom resource) for a particular subsystem is reflected in the Pod annotations. For the Analytics, Portal, and Management subsystems the **`license-use`** value can be "production" or "nonproduction". For the Gateway subsystem, the **`license-use`** value can be "production", "nonproduction", or "developer". The subsystem pod annotations are scanned by the ibm-licensing-operator, which reports license and CPU usage for each subsystem.

For more information, see License Service in the IBM Cloud Pak foundational services documentation.

Procedure

Install License Service as explained in the installation instructions in License Service in the IBM Cloud Pak foundational services documentation.
The instructions describe the appropriate License Service installation procedure for API Connect deployments, and apply to the Analytics, Portal, Management, and Gateway subsystems.

Installing the Automated API behavior testing application

Update the custom resource for installing IBM® API Connect to deploy the Automated API behavior testing application on Kubernetes.

About this task

You can install the Automated API behavior testing application as part of a new IBM API Connect deployment, or you can add it to an existing deployment. After you install the application, enable the Autotest Assist feature as explained later in this topic.
Note: It is not possible to use the Automated API behavior testing application with a two data center disaster recovery configuration (Two data center warm-standby deployment on Kubernetes and OpenShift).
Note: You may choose to enable `Autotest`, which is an optional feature that allows for automated testing of API behavior. if you decide to enable `Autotest`, monitor the following pods: `autotest` pod, `api-connect` pod, and the `cert-manager` pod, to ensure that they are running correctly and that the `Autotest` is initiating successfully.

Adding the Automated API behavior testing application to an existing deployment

Before you begin

Make sure that the following requirements are met before attempting to deploy the Automated API behavior testing application:

- The IBM API Connect subsystems are installed.
- The cert-manager is installed for use with IBM API Connect and you are using the default certificates that it generates.
  The Automated API behavior testing application requires that the IBM API Connect deployment use the cert-manager and the default certificates. Custom certificates are not supported and if used, the Automated API behavior testing application will not install correctly.

About this task

Edit the deployed CR (custom resource) for the management subsystem and add the settings for the Automated API behavior testing application.

Procedure

1. Retrieve the name of the deployed management subsystem's deployed CR by running the following command:

   ```
   kubectl get managementcluster -n <management_namespace>
   ```

2. Edit the deployed CR by running the following command:

   ```
   kubectl edit managementcluster <management-cr-name> -n <management_namespace>
   ```

3. Append the new `testAndMonitor` definition at the end of the `spec` section, making sure to adhere to the spacing used in the file.
   Attention: The `testAndMonitor` host must not conflict with any of the management hosts.

   ```
   testAndMonitor:
     enabled: true
     autoTestEnabled:true
   ```

4. Apply the updated CR by running the following command:

   ```
   kubectl apply -f management_cr.yaml -n <management_namespace>
   ```

   where *<management_namespace>* is the name of the target installation namespace in the Kubernetes cluster.

   The Automated API behavior testing application will be installed into the existing Management subsystem.

5. Check the `atm-api` and `atm-ui` pods periodically until the "READY" value is "1/1" and the "STATUS" is "Running".
   Verify that the pods are running by executing the following command:

   ```
   kubectl get pods -n <management_namespace>
   ```

6. Verify that the application deployed properly by completing the following steps:
   a. Log in to API Manager.
   b. On the home page, click the Test APIs tile.
   c. Verify that the Automated API behavior testing opens.

Including the Automated API behavior testing application in a new deployment

Before you begin

Make sure that the cert-manager is installed for use with IBM API Connect and you are using the default certificates that it generates. The Automated API behavior testing application requires that the IBM API Connect deployment use the cert-manager and the default certificates. Custom certificates are not supported and if used, the Automated API behavior testing application will not install correctly.

About this task

Edit the CR (custom resource) for the Management subsystem and add the settings for the Automated API behavior testing application.

Procedure

1. Edit the `ManagementCluster` custom resource (CR) and add the following definition for the Automated API behavior testing application.
   Append the new definition at the end of the `spec` section, making sure to adhere to the spacing used in the file.

   ```
   testAndMonitor:
     enabled: true
     autoTestEnabled:true
   ```

Attention: The `testAndMonitor` host must not conflict with any of the management hosts.

2. Apply the updated CR by running the following command:

   ```
   kubectl apply -f management_cr.yaml -n <management_namespace>
   ```

   where *<management_namespace>* is the name of the target installation namespace in the Kubernetes cluster.

   The Automated API behavior testing application will be installed with the management subsystem.

3. Check the `atm-api` and `atm-ui` pods periodically until the "READY" value is "1/1" and the "STATUS" is "Running".
   Verify that the pods are running by executing the following command:

   ```
   kubectl get pods -n <management_namespace>
   ```

4. Verify that the application deployed properly by completing the following steps:
   a. Log in to API Manager.
   b. On the home page, click the Test APIs tile.
   c. Verify that the Automated API behavior testing opens.

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just to need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + Designer: provides a command line environment for working with IBM API Connect, including API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
   - To download the toolkit from IBM Fix Central, complete the following steps:
     - Open the IBM Fix Central site in your browser.
     - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
     - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
     - In the Text field, enter `toolkit`, then click Continue.
     - Select the toolkit file that you want to download.
     - Click Continue, then follow the instructions to complete the download operation.
   - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
     - Open the Cloud Manager or API Manager user interface.
     - On the welcome page, click the Download Clients tile. The two toolkit options are listed under the Toolkit tab.
     - Click your platform alongside either the CLI option or the CLI + Designer option as required, then save the associated compressed file to your local file system.
     - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the designer_credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 5.
     - To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 4.
2. Extract the contents of the toolkit compressed file to a folder of your choice.
   The contents of the file depend on the your chosen toolkit option and platform, as follows:

   - The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.
   - The apic or apic.exe file is the CLI for IBM API Connect.
     Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + Designer option.
   - The api_designer-*platform* file is the API Designer user interface application for the specified platform.
3. Run the CLI.
   - For the macOS or Linux® platforms, complete the following steps:
     - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Make the CLI file an executable file by entering the following command:

       ```
       chmod +x download_name
       ```

       Where *download_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.
     - If you are using macOS, remove the quarantine attribute by running the following command:

```
sudo xattr -dr com.apple.quarantine apic-slim
```

- Run CLI commands as follows:

  ```
  ./apic command_name_and_parameters
  ```

  or

  ```
  ./apic-slim command_name_and_parameters
  ```

  For details of the CLI commands, see the toolkit CLI reference documentation.

- For the Windows platform, complete the following steps:
  - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
  - Run CLI commands as follows:

    ```
    apic command_name_and_parameters
    ```

    or

    ```
    apic-slim command_name_and_parameters
    ```

    For details of the CLI commands, see the toolkit CLI reference documentation.

Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.

4. Install the toolkit credentials.
   If you do not install the toolkit credentials that are provided for download, as detailed previously in the toolkit credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

   ```
   apic client-creds:set toolkit_credentials_file_path/credentials.json
   ```

   where *credentials_file_path* is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.
   Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
   To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

   ```
   apic client-creds:clear
   ```

   For increased security, an administrator can remove the default credentials from the management server by completing the following steps:
   a. Log in to the management server as an administrator; see Logging in to a management server.
   b. Delete the default credentials by running the following commands:

   ```
   apic registrations:delete toolkit --server mgmt_endpoint_url
   apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
   ```

5. Install the API Designer credentials.
   If you do not install the API Designer credentials that are provided for download, as detailed previously in the API Designer credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the **APIC_DESIGNER_CREDENTIALS** environment variable to the credentials download location, using the mechanism appropriate for your operating system.

   After you have set the **APIC_DESIGNER_CREDENTIALS** environment variable, your API Designer uses the new credentials to authenticate with the management server.

   - Windows:
     If you are using Windows, create an environment variable using one of the following methods:

     - Create a permanent environment variable so that you can start API Designer from any location on your computer:
       - Open the Environment Variables page: Click Start > Settings > System and in the "Related Settings" section of the page, click Advanced System Settings.
       - On the Advanced tab of the System Properties dialog box, click Environment Variables.
       - In the "User variables" section, click New and create an environment variables with the following settings:
         - Variable: **APIC_DESIGNER_CREDENTIALS**
         - Value: *<designer_credentials_file_path>*\designer_credentials.json where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.
       - Click OK to save the new environment variable, and then exit the dialog box.
     - If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
       - Open the Windows command prompt.
       - Run the following command to set the temporary environment variable:

         ```
         set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
         ```

         where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.

         Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.
       - Now run the following command to start API Designer:

         ```
         C:\"Program Files\API Designer\API Designer.exe"
         ```

         By default, API Designer is installed in the C:\"Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

   - Mac:
     If you are using macOS, create an environment variable using one of the following methods:

- Run the following command to set the global environment variable:

  ```
  launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
  ```

  where `<designer_credentials_file_path>` is the location where you stored the API Designer credentials JSON file.
- Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

  ```
  APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
  <designer_application_file_path>/'API Designer.app'
  ```

  where:
  - `<designer_credentials_file_path>` is the location to which you downloaded the API Designer credentials JSON file.
  - `<designer_application_file_path>` is the location to which you downloaded and uncompressed the API Designer application.

6. Start the API Designer application from the location to where you stored the extracted file.
   Note:
   - To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
     - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
     - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
   - To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see Developing your APIs and applications.

For information on using the toolkit CLI, see Using the developer toolkit command-line tool.

Customizing user-facing certificates

Convert a user-facing certificate that was generated by cert-manager to a custom certificate for an existing IBM® API Connect deployment.

The API Connect user-facing certificates are the server certificates that are presented to users of API Connect's external interfaces.

The server certificates are:

- The certificate the user's browser receives when it makes a connection to the:
  - Cloud Manager UI.
  - API Manager UI.
  - Developer portal sites.
- The certificate that is presented to callers of the API Connect platform and consumer REST APIs. The toolkit CLI uses the same REST APIs, and so is presented with the same certificates.
- The API invocation certificate. The certificate presented to callers of your published APIs. This certificate can be different on each gateway.

Remember: As per the DNS specification, wildcard certificates apply only to one level of subdomain and not more than that. For example, a certificate for `*.example.com` is not valid for `foo.bar.example.com`.
See the full list of user-facing certificates in User-facing certificates.

Note: The API invocation certificate that callers to the published APIs on your gateways see is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.
To replace the certificates for your management and portal UIs and for your management REST API endpoints, follow these steps:

1. Create the secrets that you want to use for each user-facing endpoint with the `kubectl create secret` command.
2. Edit the subsystem CR, and make the following changes for the endpoint secret you want to change:
   - In the `annotations` section, remove the following line:

     ```
     cert-manager.io/issuer: ingress-issuer
     ```

   - In the `hosts` section, update the `secretName` to the new secret that you created in step 1.

   The following example shows where to make the updates:

   ```
   spec:
     <endpoint>
       annotations:
         cert-manager.io/issuer: ingress-issuer REMOVE THIS LINE
       hosts:
       - name: <api endpoint hostname>
         secretName: REPLACE WITH YOUR SECRET
   ```

Note: By default, the secret name is identical to the cert-name. Do not create replacement custom secrets with the same name as the default secrets.

Changing deployment profiles on Kubernetes and OpenShift

You can change an API Connect installation to use different deployment profiles.

About this task

After you complete initial installation of the API Connect subsystems, you can change to another of the profiles that are supported for the subsystem. For more information on the available profiles, see: Deployment and component profiles.

Important considerations:

- If you are changing from a one replica profile to a three replica profile, ensure that you have three replica profile hardware (at least 3 worker nodes).
- Based on the resources configured for each microservice in the profile, there might be downtime during the profile change.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Management subsystem:
   a. Verify that subsystem is in `Running` state.

      ```
      kubectl get ManagementCluster
      ```

   b. Edit the CR:

      ```
      kubectl edit ManagementCluster
      ```

      Change `spec.profile` value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in `Running` state.

      ```
      kubectl get ManagementCluster
      ```

2. Developer Portal subsystem:
   a. Verify that subsystem is in `Running` state.

      ```
      kubectl get PortalCluster
      ```

   b. Edit the CR:

      ```
      kubectl edit PortalCluster
      ```

      Change `spec.profile` value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in `Running` state.

      ```
      kubectl get PortalCluster
      ```

3. Analytics subsystem:
   Note: If you have a three replica profile, and want to change to one replica, you must first change your analytics configuration to shared storage. Dedicated storage is not supported on the one replica profile.
   a. Verify that subsystem is in `Running` state.

      ```
      kubectl get AnalyticsCluster
      ```

   b. Edit the Analytics CR:

      ```
      kubectl edit AnalyticsCluster
      ```

      Change `spec.profile` value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in `Running` state.

      ```
      kubctl get AnalyticsCluster
      ```

4. Gateway subsystem
   a. Verify that subsystem is in `Running` state.

      ```
      kubectl get GatewayCluster
      ```

   b. Edit the CR:

      ```
      kubectl edit GatewayCluster
      ```

      Change `spec.profile` value to the new profile you want to use.

   c. When switching from one replica profile to a three replica profile, wait for the microservice to scale up. When switching from a three replica profile to a one replica profile, wait for the microservice to scale down.
   d. Verify that subsystem is in `Running` state.

      ```
      kubectl get GatewayCluster
      ```

Changing deployment profiles on OpenShift top-level CR

You can change an API Connect top-level CR installation to use different profiles.

Before you begin

This task assumes that you have already deployed an API Connect cluster as explained in Deploying on OpenShift and Cloud Pak for Integration. If you are changing from a one replica profile to a three replica profile, ensure that you have three replica profile hardware (3 worker nodes) available. For more information on the available profiles, see: Deployment and component profiles.

Note: If you have a three replica profile, and want to change to one replica, you must first change your analytics configuration to shared storage. Dedicated storage is not supported on the one replica profile.

Procedure

1. Verify that the API Connect cluster is in the **Ready** state by running the following command:

   ```
   oc get apiconnectcluster
   ```

2. Update the API Connect Cluster CR:
   a. Open the API Connect Cluster CR in edit mode by running the following command:

      ```
      oc edit apiconnectcluster <APIC-instance-name>
      ```

   b. In the CR, change the **spec.profile** value to the profile that you want to use.
   c. Save the change by running the following command: **:wq**
3. Wait for microservice to scale up, or scale down, as needed.
4. Verify that the API Connect cluster is in the **Ready** state by running the following command:

   ```
   oc get apiconnectcluster
   ```

Changing the deployment profile on Cloud Pak for Integration

You can change an API Connect installation to use a different profile.

Before you begin

This task assumes that you have already deployed an API Connect cluster as explained in Deploying on OpenShift and Cloud Pak for Integration. If you are switching from a one replica profile to a three replica profile, ensure that you have three replica profile hardware (3 worker nodes) available. For more information on the available profiles, see: Deployment and component profiles.

Note: If you have a three replica profile, and want to change to one replica, you must first change your analytics configuration to shared storage. Dedicated storage is not supported on the one replica profile.

Procedure

1. Verify that the API Connect cluster is in the **Ready** state.
   Open the IBM Cloud Pak Platform UI, locate the API Management capability on the Integration instances tab, and verify that the state displays as **Ready**. Leave the page open for the next step.

2. Update the API Management instance:
   a. In the Platform UI, click the overflow menu next to the instance and select Edit.
   b. In the Details section of the deployment pages, navigate to the Deployment profile field.
   c. Click the field and select the new deployment profile.
3. Click Update to save the change.
4. Wait for microservice to scale up, or scale down, as needed.
5. Verify that the status for the API Management instance displays as **Ready**.

Replica override for microservices

Modify the replica count for microservices by using template overrides for Custom Resources.

When API Connect is deployed, the deployment profile you select drives the number of replicas to be used for most deployment. For one replica profiles, specified by **n1x....**, the replica count is 1. For three replica profiles, specified by **n3x...**, replica count is 3. Note, however, that for Cloud Pak for Integration the API Connect Cluster profile **n3xc4.m16** replica count is 1.

You can override the replica count for individual deployments by using template overrides.

- Template overrides are a piece of yaml that should be added to the Kubernetes custom resource. The examples provided in this topic show only that the **template:** element should be under the main **spec:** element of a CR. The rest of the CR is not shown.
- Specification of microservice overrides in CP4I requires prefixing the microservice name with a designator for the subsystem type, as follows:
  - Management subsystem: **mgmt-**
  - Gateway: **gw-**
  - Analytics: **a7s-**

  For example, for the **apim** Management microservice, use **apim** when defining the override for OpenShift (or Kubernetes), but use **mgmt-apim** for a CP4I override.

Management subsystem

For a Management CR in Kubernetes or OpenShift, the following override specifies 5 replicas for the **apim** deployment:

```
spec:
  template:
  - name: apim
    replicaCount: 5
```

You can also configure replicate count through a similar template override for:

- juhu
- ldap
- lur

The same override for CP4I:

```
spec:
  template:
  - name: mgmt-apim
    replicaCount: 5
```

On CP4I, you can also configure replicate count through a similar template override for:

- mgmt-juhu
- mgmt-ldap
- mgmt-lur

Gateway subsystem

The following override is supported for a Gateway CR in Kuberneter or OpenShift:

```
spec:
 template:
  - name: datapower
    replicaCount: 5
```

The same override for CP4I:

```
spec:
  template:
  - name: gw-datapower
    replicaCount: 5
```

Analytics subsystem

The Analytics microservices that can be scaled using template override are:

- director
- ingestion
- mtls-gw
- storage
  Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

On CP4I, you can also configure replica count through a similar template override for:

- a7s-directory
- a7s-ingestion
- a7s-mtls-gw
- a7s-storage
  Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

Enabling Developer Portal feature flags on Kubernetes

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default Value	Pod	Container	Description

Feature flag name	Default Value	Pod	Container	Description

`PORTAL_SKIP_WEB_ENDPOINT_VALIDATION`	`true`	`www`	`admin`	Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible.
				
				Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the `portal-www` pod, and `admin` container logs:
				
				`An error occurred contacting the provided portal web endpoint: example.com`
				`The provided Portal web endpoint example.com returned HTTP status code 504`
				
				You can disable the check by setting this flag to `false`.

`ENABLE_TRUSTED_REVERSE_PROXY`	`false`	`www`	`admin`	Controls whether the Drupal `trusted_reverse_proxy` module can manage the reverse proxies list.
				
				If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal `trusted_reverse_proxy` module, and setting this feature flag to `true`.
				
				The Drupal module inspects the `x-forwarded-for` headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in `X-Forwarded-For: <client>, <proxy1>, <proxy2>`, the client IP `<client>` will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy.
				
				To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the `x-forwarded-for` header is passed through to the `portal-www` pod. For example, the default behavior of the `nginx-ingress-controller` is to ignore the inbound `x-forwarded-for` header, and create a new one. To change this behavior, update the `nginx-ingress-controller` `configmap` with the following information:
				
				`data:`
				`  compute-full-forwarded-for: "true"`
				`  use-forwarded-headers: "true"`
				
				Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the `x-forwarded-for` header.

Procedure

1. If API Connect is already deployed, retrieve the name of the deployed CR for the Developer Portal subsystem by running the following command:

   ```
   kubectl get portalcluster -n <portal_namespace>
   ```

   If API Connect yet is not yet deployed, skip this step.

2. Edit the `portal` CR by running the following command:

   ```
   kubectl edit portalcluster <portal-cr-name> -n <portal_namespace>
   ```

3. In the editor, append the feature flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the `trusted_reverse_proxy` feature.

   ```
   spec:
   ...
     template:
     - containers:
       - env:
           - name: ENABLE_TRUSTED_REVERSE_PROXY
             value: true
         name: container
       name: pod
   ```

   Where:
   - *container* is the name of the portal container.
   - *pod* is the name of the portal pod.

   Note: You can add multiple feature flags to the CR.
4. Save the update.
   The Developer Portal subsystem is updated to enable or disable features as specified.

Enabling Developer Portal feature flags on OpenShift and Cloud Pak for Integration

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default Value	Pod	Container	Description

`PORTAL_SKIP_WEB_ENDPOINT_VALIDATION`	`true`	`www`	`admin`	Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible.
				
				Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the `portal-www` pod, and `admin` container logs:
				
				`An error occurred contacting the provided portal web endpoint: example.com`
				`The provided Portal web endpoint example.com returned HTTP status code 504`
				
				You can disable the check by setting this flag to `false`.

`ENABLE_TRUSTED_REVERSE_PROXY`	`false`	`www`	`admin`	Controls whether the Drupal `trusted_reverse_proxy` module can manage the reverse proxies list.
				
				If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal `trusted_reverse_proxy` module, and setting this feature flag to `true`.
				
				The Drupal module inspects the `x-forwarded-for` headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in `X-Forwarded-For: <client>, <proxy1>, <proxy2>`, the client IP `<client>` will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy.
				
				To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the `x-forwarded-for` header is passed through to the `portal-www` pod. For example, the default behavior of the `nginx-ingress-controller` is to ignore the inbound `x-forwarded-for` header, and create a new one. To change this behavior, update the `nginx-ingress-controller` `configmap` with the following information:
				
				`data:`
				`  compute-full-forwarded-for: "true"`
				`  use-forwarded-headers: "true"`
				
				Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the `x-forwarded-for` header.

Procedure

1. If API Connect is already deployed, retrieve the name of the deployed CR by running the following command:

   `oc get apiconnectcluster -n <APIC_namespace>`

   If API Connect yet is not yet deployed, skip this step.

2. Edit the `apiconnectcluster` CR by running the following command:

   `oc edit apiconnectcluster <APIC_instance_name> -n <APIC_namespace>`

3. In the CR, append the feature flag definition to the end of the `spec.portal` section, making sure to adhere to the spacing used in the file.
   You can add multiple feature flags as follows:

```
spec:
  template
  - containers:
      - env:
          - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
            value: 'true'
        name: admin
    name: ptl-www
```

```
spec:
  template
  - containers:
      - env:
          - name: ENABLE_TRUSTED_REVERSE_PROXY
            value: 'true'
        name: admin
    name: ptl-www
```

4. Close and save the file with the following command:

   `:wq`

   The Developer Portal subsystem is updated to enable or disable features as specified.

Enabling UI feature flags on Kubernetes

Use a template override to update the installation CR with settings that control UI features.

About this task

You can add a template override to the Management subsystem CR and use it to control whether specific features are available in the UI. Some features can be optionally disabled by users (by disabling them in the browser) provided you have enabled the feature for the cluster as a whole. Table 1 describes the available feature flags.

Table 1. Flags and settings for controlling UI features

Feature ID	Default Value	Partial Override For	Description
`ffAdvancedPublish`	`true`		Enable advanced publish option (deprecated)
`allOmniSearch`	`true`		Enables OmniSearch for all lists. This flag is used in conjunction with other flags.
`draftsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for drafts list
`catalogProductsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for catalog
`orgsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for org lists
`appsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apps
`subscriptionsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for subscriptions, if disabled, subscription lists will be removed from catalog list
`requestedApprovalsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for requested approvals
`approvalTasksOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for approvals
`productApisOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apis within products
`membersOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for member lists

Procedure

1. If you already deployed API Connect, retrieve the name of the deployed CR for the Management subsystem by running the following command:

   ```
   kubectl get managementcluster -n <management_namespace>
   ```

   If you did not deploy API Connect yet, skip this step.

2. Edit the `management` CR by running the following command:

   ```
   kubectl edit managementcluster <management-cr-name> -n <management_namespace>
   ```

3. In the editor, append the feature-flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the OmniSearch feature on all possible UI pages.

   ```
   spec:
     template:
       - name: ui
         containers:
         - name: ui
           env:
             - name: APIC_UI_FEATURES
               value: allOmniSearch=always
   ```

   `APIC_UI_FEATURES` is a URL-encoded string. Each parameter is formed as `featureId=$featureValue`, and you can list multiple parameters with the `&` delimiter (`featureId=$featureValue&featureId=$featureValue`).

   Use the `featureId` values from Table 1. For each feature, specify one of the following `featureValue` settings:

   - `true` - On by default, but can be overridden by the user, for their browser alone
   - `false` - Off by default, but can be overridden by the user, for their browser alone
   - `never` - Off regardless of browser setting, disabled in feature flag page
   - `always` - On regardless of browser setting, disabled in feature flag page

4. Save the update.
   The cluster is updated to enable or disable features as specified.

Enabling UI feature flags on OpenShift and Cloud Pak for Integration

Use a template override to update the installation CR with settings that control UI features.

About this task

You can add a template override to the Management subsystem CR and use it to control whether specific features are available in the UI. Some features can be optionally disabled by users (by disabling them in the browser) provided you have enabled the feature for the cluster as a whole. Table 1 describes the available feature flags.

Table 1. Flags and settings for controlling UI features

Feature ID	Default Value	Partial Override For	Description

Feature ID	Default Value	Partial Override For	Description
`ffAdvancedPublish`	`true`		Enable advanced publish option (deprecated)
`allOmniSearch`	`true`		Enables OmniSearch for all lists. This flag is used in conjunction with other flags.
`draftsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for drafts list
`catalogProductsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for catalog
`orgsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for org lists
`appsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apps
`subscriptionsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for subscriptions, if disabled, subscription lists will be removed from catalog list
`requestedApprovalsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for requested approvals
`approvalTasksOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for approvals
`productApisOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apis within products
`membersOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for member lists

Procedure

1. If you already deployed API Connect, retrieve the name of the deployed CR by running the following command:

   ```
   oc get apiconnectcluster -n <APIC_namespace>
   ```

   If you did not deploy API Connect yet, skip this step.

2. Edit the `apiconnectcluster` CR by running the following command:

   ```
   oc edit apiconnectcluster <APIC_instance_name> -n <APIC_namespace>
   ```

3. In the CR, append the feature-flag definition to the end of the `spec.management` section, making sure to adhere to the spacing used in the file.
   The following example enables the OmniSearch feature on all possible UI pages.

   ```
   spec:
     management:
       template:
         - name: ui
           containers:
           - name: ui
             env:
               - name: APIC_UI_FEATURES
                 value: allOmniSearch=always
   ```

   `APIC_UI_FEATURES` is a URL-encoded string. Each parameter is formed as `featureId=$featureValue`, and you can list multiple parameters with the `&` delimiter (`featureId=$featureValue&featureId=$featureValue`).

   Use the `featureId` values from Table 1. For each feature, specify one of the following `featureValue` settings:

   - `true` - On by default, but can be overridden by the user, for their browser alone
   - `false` - Off by default, but can be overridden by the user, for their browser alone
   - `never` - Off regardless of browser setting, disabled in feature flag page
   - `always` - On regardless of browser setting, disabled in feature flag page

4. Close and save the file with the following command:

   ```
   :wq
   ```

   The cluster is updated to enable or disable features as specified.

Adding external annotation to routes and ingresses

You can add external annotations and labels to routes and ingresses.

You can configure annotations for ingress and routes in API Connect on subsystems (Management, Portal, Analytics, and Gateway) or API Connect custom resource (CR). Depending on your needs, you can choose from the following two approaches to configure the annotations in the CR.

- Using custom annotations
- Using pattern matching for external annotation

Using custom annotations

This approach is suitable when you manually define and manage the annotations in the CR. These annotations are carried over to the routes and ingresses managed by the API Connect operator.

The following example demonstrates the process of configuring external annotation using Management CR.

Example

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  name: management
spec:
```

```
  apiManagerEndpoint:
    annotations:
      cert-manager.io/issuer: ingress-issuer
      my-custom-key: my-custom-value
    hosts:
    - name: manager.example.com
      secretName: apim-endpoint
```

You can use this custom annotation when,

- You have a static set of annotations known in advance.
- You want the API Connect operator to consistently manage these annotations.
- You don't expect these annotations to change dynamically.

Using pattern matching for external annotation

You can use this method when annotations or label patterns are generated and managed by an external process, and you want these to persist on the routes and ingresses without the API Connect operator removing them. This is especially useful when you are using a third-party load balancer which might add their own annotations.

By using the external annotation, you can preserve custom external annotations and labels when the key matches the regular expression. Usage of external annotation is supported during creation and update processes in OpenShift® Container Platform (OCP), Cloud Pak for Integration (CP4I), and Kubernetes (K8s).

The following example demonstrates the process of configuring external annotation using Management CR.

Example

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementCluster
metadata:
  name: management
  annotations:
    apiconnect-operator/external-key-pattern: ".*myloadbalancerprovider.*"
spec:
```

You can use this custom annotation when,

- Annotations are dynamically generated and managed by an external process (for example, a load balancer controller).
- You need these annotations to persist without interference from the API Connect operator.

Note: If you use an invalid regex pattern, a webhook validation error occurs during installation or update. For more information on Golang regular expression syntax, see https://pkg.go.dev/regexp/syntax.

Advanced configuration for the management subsystem

Specify advanced configuration for the management subsystem.

See:

- **Updating management subsystem password, keys, and secrets**
  Update the cloud administrator password, the key for encrypted database fields, and the `client_ID` and `client_secret` values for the management subsystem in an API Connect deployment.
- **Configuring maximum size of client requests to the Management subsystem**
  You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.
- **Setting rate limits for public APIs on the management service for a Kubernetes environment**
  Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- **Enabling API discovery on Kubernetes**
  You can optionally configure API discovery in IBM® API Connect on a Kubernetes, OpenShift, or IBM Cloud Pak for Integration deployment by enabling the API discovery service.
- **Enabling governance on Kubernetes**
  You can optionally configure governance in IBM API Connect on a Kubernetes, OpenShift, or IBM Cloud Pak for Integration deployment by enabling the governance service.
- **Configuring monetization on Kubernetes**
  You can optionally configure monetization in API Connect on a Kubernetes deployment by enabling the billing microservice.
- **Enabling billing feature on OpenShift and Cloud Pak for Integration**
  You can optionally configure monetization in API Connect on Red Hat OpenShift and IBM Cloud Pak for Integration by enabling the billing feature.
- **Restarting the Management subsystem pods**
  How to restart Management subsystem pods in your API Connect deployment.
- **Disabling the PDB for the management EDB database**
  Disable `PodDisruptionBudget` (PDB) for replica management subsystems.
- **Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later**
  This section describes the default affinity, nodeSelector, and toleration settings of EDB Postgres and Operator pods and examples of how to customize them.

Updating management subsystem password, keys, and secrets

Update the cloud administrator password, the key for encrypted database fields, and the `client_ID` and `client_secret` values for the management subsystem in an API Connect deployment.

- **Changing the cloud administrator password**
  Update the cloud administrator password for the management subsystem using the Cloud Manager UI, the toolkit CLI, or an API call.
- **Changing the database encryption key**
  Replace the value of the secret that is used for encrypting database fields in the management subsystem.
- **Changing the registration client_id and client_secret for applications**
  Change the registration credentials (the `client_id` and `client_secret`) for applications provided by the management subsystem.

Changing the cloud administrator password

Update the cloud administrator password for the management subsystem using the Cloud Manager UI, the toolkit CLI, or an API call.

About this task

In the management subsystem for an API Connect on-premises deployment, the administrator is called the *cloud administrator* and works with the management server to configure the deployment of the local server cloud. Updating the cloud administrator password for the management subsystem requires no service interruption because the change takes place immediately.

You can change the cloud administrator's password using any of the following methods.

Note: Passwords must contain eight or more characters, with at least one character from three of the following categories: lowercase letters, uppercase letters, numerals, and punctuation (for example: ! $ # %). The same character cannot be used more than twice consecutively.

Cloud Manager UI

1. Log in to the Cloud Manager UI.
2. Change your Cloud Manager password.

Toolkit CLI

1. Run the `apic login` command to log in to a management server.
2. Run the `apic me:change-password` command to change your password.

API call

1. Run the `apic login` command to log in to a management server.
   You must log in to a management server with the toolkit CLI before you can call the API Connect APIs.
2. Execute the `/api/me/change-password` API call. as explained in the "Resource: Me" section of the IBM API Connect Platform - Cloud Management API.

The next time that you log in as the cloud administrator, you must use the new password.

Changing the database encryption key

Replace the value of the secret that is used for encrypting database fields in the management subsystem.

Before you begin

Take a backup of your existing management database encryption key. If you need to restore a management database backup, you must have the encryption key that was in use at the time the database backup was created.

To take backup of your encryption key:

1. Identify the name of the management database encryption secret:

   ```
   kubectl get mgmt <mangement CR name> -o=jsonpath='{.status.encryptionSecret}'
   ```

   where *<mangement CR name>* can be determined by running:

   ```
   kubectl get mgmt
   ```

2. Copy the secret to a YAML file:

   ```
   kubectl get secret <management enc secret> -o yaml > management_enc_key_backup_<date>.yaml
   ```

The key is backed up to the file management_enc_key_backup_*<date>*.yaml. Set *<date>* to the current date, for example management_enc_key_backup_20240101.yaml, so that you can identify when this backup was taken.
Keep your backed up encryption secret with your management infrastructure configuration backup: Taking a management infrastructure configuration backup. If you want to restore a database backup that was taken when a previous encryption key was in use, then see restore backup.

About this task

This update does not require an outage; however some operations might take longer than usual due to database locking.

Procedure

1. Create a file called rotate_mgmt_enc_secret.yaml, and paste in the following contents:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
  name: rotate-secret
spec:
  managementCluster: <mangement CR name>
  rotateEncryptionSecret:
    rotate: true
```

Note: If your deployment was originally installed at V2018.4.1, then the database encryption key is called *managementUpgradeName*`-encryption-secret`.

2. Run the following command to apply the `rotate-secret` CR:

```
kubectl create -f rotate_mgmt_enc_secret.yaml
```

The update can take a few minutes. You can monitor the progress with:

```
kubectl get managementsecretrotation
```

The update is complete when the status shows `Completed`:

```
NAME            READY   STATUS      AGE
rotate-secret   1/1     Completed   13m
```

If you installed API Connect on VMware and if you want to update the management encryption secret on VMware, then you can now use the `apicup` command to rotate the encryption secret without needing to open a support case. For a standalone installation, run the following command:

```
apicup subsys rotate-secrets <stack-name> --rotate-encryption-secret
```

For 2DC setup, run the following command:

```
apicup subsys rotate-secrets <active-stack-name> --rotate-encryption-secret
```

What to do next

If you need to restore a management database backup that was taken before you updated the encryption key, then you must restore your previous encryption key from your backup.

1. Edit your secret backup file: management_enc_key_backup_*<date>*.yaml and change `metadata.name` to a unique name for your backup secret. Delete all other `metadata` contents. Your updated YAML file should look like this:

```
apiVersion: v1
data:
  encryption_secret.bin:
If7HlVzZeAgrYrwvcEhv1Ub0LVXNQsN0mGISy1GvYXKA4d1tSWLB80hB89sn+VvN0/vAVTU90AP6jPOsi5LpOaddfoqT85ugvjEwHLnEtSI6CbEr05NtMUwJGA
r5/KWfjj6mwCn+EMp4VBsEDppU54yvycyb7iBLRtGyrPktTaw=
kind: Secret
metadata:
  name: backup_mgmt_encryption_secret
type: Opaque
```

2. Restore the encryption secret from your updated backup file:

```
kubectl create -f management_enc_key_backup_<date>.yaml
```

3. Verify that the backup secret was created:

```
kubectl get secrets
```

You should see your restored backup secret in the output:

```
NAME                                TYPE             DATA   AGE
...
backup_mgmt_encryption_secret       Opaque           3      10s
...
```

4. In your mgmtrestore_cr.yaml file, add the property `spec.mgmtEncKeyName` and set it to your newly created backup secret name:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementRestore
metadata:
  generateName: management- # this the prefix for the name of the restore CR that is created
spec:
  backupName: <backup CR name>
  subsystemName: <management CR name>
  mgmtEncKeyName: backup_mgmt_encryption_secret
```

The encryption key that is contained in `backup_mgmt_encryption_secret` is copied to your active encryption secret. After you restore the backup, you might want to update the encryption key again (for the same reason that you previously updated the secret).

For more information about management database backup restore, see Restoring from a management database backup.

If you have a two data center disaster recovery deployment, you must copy the updated encryption secret to your warm-standby data center. Follow these steps:

1. Extract the management database encryption secret from the active data center:

```
kubectl get secret <mgmt encryption secret> --template='{{ index .data "encryption_secret.bin" }}' > mgmt-enc-secret.txt
```

2. Verify that the mgmt-enc-secret.txt file contains your secret:

```
cat mgmt-enc-secret.txt
```

Expected output should be a long string, for example:

```
YSXft4YoApS+UJHpaXjdu8OUovFGhLT9YsBaWeRCI5sUigPdchY/cq18Z5UKaW5afZDXxQDWUcY6tx9xTXVGzEm9oZCDV1hmq4mu7qM015rBjZIJ7FPrA3gNgx
flxim9SORSybnhW2JT6S41ZH9QJwfUtIUUpe981h8sraSEtOQ=
```

3. In your warm-standby data center, identify the name of the management database encryption secret:

```
kubectl get mgmt <mangement CR name> -o=jsonpath='{.status.encryptionSecret}'
```

4. Update the warm-standby secret with the secret from the active that you obtained in step 1:

```
kubectl patch secret <warm-standby enc secret name> -p "{\"data\": {\"encryption_secret.bin\":\"$(<mgmt-enc-
secret.txt)\"}}"
```

Changing the registration `client_id` and `client_secret` for applications

Change the registration credentials (the **client_id** and **client_secret**) for applications provided by the management subsystem.

About this task

Update the application registration **client_id** and **client_secret** by changing the Kubernetes secret containing them. The **apim** file-watcher detects the change and automatically updates the following secrets in the database:

- toolkit: **management-cli-cred** (Customer facing)
  When you update the secret for the toolkit, users must download and install new toolkit credentials as explained in Installing the toolkit.
- consumer-toolkit: **management-ccli-cred** (Customer facing)
  When you update the secret for the toolkit, users must download and install new toolkit credentials as explained in Installing the toolkit.
- designer: **management-dsgr-cred** (Customer facing)
  When you update the secret for API Designer, users must download and install new credentials as explained in Installing the toolkit.
- atm: **management-atm-cred** (Internal)
- governance: **management-governance-cred** (Internal)
- consumer-ui: **management-cui-cred** (Internal)
- juhu: **management-juhu-cred** (Internal)
- ui: **management-ui-cred** (Internal)
  The API Manager and Cloud Manager read the credentials from the back-end on start-up.

When you update registration credentials, the registration name that is associated with the updated secret changes. Table 1 lists the registration secrets with the default registration name and the pattern used for generating updated registration names for each secret. The new registration names follow the patterns shown in the table. The second and subsequent updates append a number to the name; for example, **toolkit-application-registration**, **toolkit-application-registration0** and then **toolkit-application-registration1**.

Table 1. Secret names and the corresponding default, and new, registration names for each secret

Secret	Default registration name	New registration name pattern
management-cli-cred	toolkit-default	toolkit-application-registration*
management-ccli-cred	consumer-toolkit-default	consumer-toolkit-application-registration*
management-dsgr-cred	designer-default	designer-registration*
management-atm-cred	atm-default	atm-default*
management-governance-cred	compliance-default	compliance-default*
management-cui-cred	consumer-ui-default	consumer-ui-default*
management-juhu-cred	juhu-default	juhu-default*
management-ui-cred	ui-default	ui-default*

Procedure

1. To renew an internal certificate, complete the following steps:
   a. Create a ManagementSecretRotation CR (for example, operationcr.yaml) with contents similar to the following example, and list the secrets that you want to update:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
  name: rotate-credentials
spec:
  managementCluster: management
  rotateClientIDandSecret:
    secrets:
    - management-ui-cred
    - management-cui-cred
    - management-juhu-cred
    - management-atm-cred
```

   b. Apply the CR by running the following command:

```
kubectl create -f operationcr.yaml -n namespace
```

   where:

   - ***namespace*** is the namespace where you installed the management subsystem
   - operationcr.yaml is the file the contains the CR

Applying the resource updates the credential for the specified secrets with new values.

2. To update customer-facing credentials, complete the following steps:
   a. For each of the credential secrets, run the following command to update the `client_id` and `client_secret`:

      ```
      kubectledit secret credential_secret_name -n namespace
      ```

      where:
      - ***namespace*** is the namespace where the management subsystem is installed.
      - ***credential_secret_name*** is the name of the secret that you want to update.

      The response opens the secret in a text editor as shown in the following example:

      ```
      apiVersion: v1
      data:
        credential.json:
      eyAiaWQiOiAiNTY3MTYyNjYtZDE0Zi00ODZmLWI0MWYtZTE3MzZkZTg3NjE0IiwgInNlY3JldCI6ICJmYjU5MDdhNy0zMjZjLTQ4ZWYtYjQ0ZC1hMTI5ZmZkMzNiMTEiIH0=
      ```

      In the secret, the value of `credential.json` is a base64 encoded string of the following JSON format. Decode it first, modify the values of `id` and `secret`, and encode back as base64 and paste it in the secret. (Note that either `id` or `secret` or both can be updated, but if the credentials have been compromised then its recommended to update both id and secret). For example:

   b. Decode the value of `credential.json`.
      To decode the value, copy it from the secret in step 2a, and paste it between the quotation marks as the ***encoded_value*** in the following command:

      ```
      echo "encoded_value" | base64 --decode
      ```

      Using the value returned in step 1, the command looks like the following example:

      ```
      echo
      "eyAiaWQiOiAiNTY3MTYyNjYtZDE0Zi00ODZmLWI0MWYtZTE3MzZkZTg3NjE0IiwgInNlY3JldCI6ICJmYjU5MDdhNy0zMjZjLTQ4ZWYtYjQ0ZC1hMTI5ZmZkMzNiMTEiIH0=" | base64 --decode
      ```

      The response displays decoded values of the `id` and `secret`, as in the following example:

      ```
      { "id": "56716266-d14f-486f-b41f-e1736de87614", "secret": "fb5907a7-326c-48ef-b44d-a129ffd33b11" }
      ```

   c. Update the values of `id` and `secret`.
      You can use any string that meets the following requirements:
      - The `id` (it becomes `client_id`) must be unique across all credentials in your entire deployment.
      - The values must be enclosed in straight quotation marks. To make sure you use the correct character, create the values in a plain text editor.

   d. Encode the updated `id` and `secret` as base64 by running the following command:

      ```
      echo -n '{ "id": "new_id", "secret": "new_secret" }' | base64
      ```

      Replace ***new_id*** and ***new_secret*** with your updated values. For example:

      ```
      echo -n '{ "id": "21034840-b439-a393-4482-a948bcb39603", "secret": "43450ab9-4038-acf0-0498-793b29ade396" }' | base64
      ```

      Returns the following base640-encoded value:

      ```
      aWQ6IDIxMDM0ODQwLWI0MzktYTM5My00NDgyLWE5NDhiY2IzOTYwMywgc2VjcmV0OiA0MzQ1MGFiOS00MDM4LWFjZjAtMDQ5OC03OTNiMjlhZGUzOTY=
      ```

   e. Paste the newly coded value for `credential.json` into the secret.
   f. Save the secret.
      When you save the secret, the logs in the `apim` pods indicate that a new registration was created. For example, if the `client_id` changed, the display looks similar to the following messages

      ```
      2020-09-14T09:55:58.331Z bhendi:audit [ce64fd50-e4de-4cfb-baa7-7379a892b2c9] Created internal resource "Registration"

2020-09-14T11:00:52.377Z bhendi:audit [866bb70b-3bb5-4ac3-9a59-0b60ade7feb2] Created internal resource "Registration"
'user-interface-registration (User Interface Registration)' (id=bb02b3bf-5e80-4547-842e-e60f4aa1d0ce,
url=/api/cloud/registrations/bb02b3bf-5e80-4547-842e-e60f4aa1d0ce, namespace=cloud)
2020-09-14T11:00:52.377Z audit [866bb70b-3bb5-4ac3-9a59-0b60ade7feb2] Creating a new registration for type, ui, with
client_id: ui-client-id.
```

g. If the response shows any errors, you must correct the errors.
When the logs show no errors, the saved values are updated in the management subsystem's database.

h. Confirm that the new registration exists in the registrations list by running the following toolkit CLI command:

```
apic --server server registrations:list
```

where ***server*** is the management server endpoint URL.

i. Verify that the updated registration is now in effect by running the following toolkit CLI command:

```
apic --server server registrations:get new_registration_name --output -
```

where:

- ***server*** is the management server endpoint URL
- ***new_registration_name*** is the new registration name (including any numeric suffix) following the patterns in Table 1.

j. Save the old registration (refer to Table 1 to determine the previous registration's file name) in case you need it when restoring an older backup.
Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created.

k. If you updated the registration credentials for API Designer or the toolkit, inform users so they can download new credentials.
Users can download and set up new credentials as explained in Installing the toolkit. Other credentials are updated automatically and require no actions from the user.

Configuring maximum size of client requests to the Management subsystem

You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.

About this task

The default maximum size is 8 megabytes. You can increase this value.

Increasing the setting can be useful if you get errors when using the CLI to import a large API. Example error:

```
HTTP/1.1 413 Request Entity Too Large
```

Procedure

1. Edit the Management CR. Refer to the Management CR templates:

```
spec:
  ...
  ...
  template:
  - name: juhu
    containers:
    - name: juhu
      env:
      - name: CLIENT_MAX_BODY_SIZE
        value: "12m"
```

Note that the default value is `"8m"`. The `template:` entry must be indented two spaces, and be located within the `spec:` element.

2. Apply the changes:

```
kubectl -n <namespace> apply -f management_cr.yaml
```

Setting rate limits for public APIs on the management service for a Kubernetes environment

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

Before you begin

Note:

- This article does not apply to the IBM® DataPower® Gateway component that is a part of the IBM API Connect solution.
- This article applies to third-party software that IBM does not control. As such, the software may change and this information may become outdated.

These instructions assume you have a working Kubernetes environment with the kubectl command-line tool installed, and that you understand how to manage Kubernetes. For more information, see https://kubernetes.io.

About this task

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

Rate limits are calculated as requests per seconds per client.

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: **`429 Too Many Requests`**.

Procedure

- Configure the ingress-nginx-ingress-controller to pass the real client IP address:
  1. Set the **`use-proxy-protocol`** parameter to **`true`** by entering the following command:

     ```
     kubectl edit ConfigMap -n kube-system ingress-nginx-ingress-controller
     ```

  2. In the ConfigMap, set the following: **`use-proxy-protocol: "true"`**
- Set a rate limit:
  1. You can add a **`template:`** value in your subsystem CR to provide an override.
     For example, the Management CR template value can be:

     ```
     spec:
       ...
       template:
       - name: juhu
         containers:
         - name: juhu
           env:
           - name: RATE_LIMIT_PER_CLIENT
             value: "10"
           - name: LIMIT_REQUEST_OPTION
             value: "burst=10 nodelay"
     ```

     Note that the **`template:`** entry must be indented two spaces, and must be located in the **`spec:`** element.

     In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

     The **`rateLimitPerClient`** property sets **`rate`**, and **`limitRequestOption`** sets **`[burst=number] [nodelay | delay=number]`** in the following nginx configuration:

     ```
     limit_req_zone key zone=name:size rate=rate;
     limit_req zone=name [burst=number] [nodelay | delay=number];
     ```

     Note that **`zone`** has been pre-defined and can't be configured. For more details, see the nginx doc http://nginx.org/en/docs/http/ngx_http_limit_req_module.html.

  2. Apply the changes:

     ```
     kubectl -n <namespace> apply -f management_cr.yaml
     ```

  3. Validate that the juhu pod has restarted by listing the pods:

     ```
     kubectl get pods -n <namespace> | grep juhu
     ```

  4. Check the AGE column to ensure a new juhu pod has started.
  5. If the older juhu pod is still running, delete it with the following command:

     ```
     kubectl delete pods -n <namespace> <old-juhu-pod>
     ```

- Disable a rate limit:
  1. Validate that the juhu pod has restarted by listing the pods:

     ```
     kubectl get pods -n <namespace> | grep juhu
     ```

  2. Check the AGE column to ensure a new juhu pod has started.
  3. If the older juhu pod is still running, delete it with the following command:

     ```
     kubectl delete pods -n <namespace> <old-juhu-pod>
     ```

Enabling API discovery on Kubernetes

You can optionally configure API discovery in IBM® API Connect on a Kubernetes, OpenShift, or IBM Cloud Pak for Integration deployment by enabling the API discovery service.

About this task

The API discovery service is an optional add-on to API Connect that can be used to discover and add APIs to your API development process.

Note:

- These instructions apply only to Kubernetes, OpenShift, and IBM Cloud Pak for Integration installations. For VMware installations, see Enabling API discovery on VMware.
- APIs cannot be discovered and added to your deployment until the API discovery service is enabled.
- If you're using a two data center disaster recovery (2DCDR) deployment, the API discovery service must be enabled on both the active and warm-standby centers. Enable the service on the warm-standby data center first, and then the active center.
- If you enable the API discovery service, the backups that you take can be restored only onto a management subsystem that also has the API discovery service enabled.

To enable or disable the API discovery service, you must configure the Management subsystem custom resource (CR) file. See the following instructions:

- **Enabling the API discovery service as part of a new deployment**
- **Enabling the API discovery service as part of an existing deployment**
- **Disabling the API discovery service**

After the API discovery service is enabled, API discovery resources can be created. For more information, see API discovery.

Procedure

- **Enabling the API discovery service as part of a new deployment**
  Edit the CR file for the Management subsystem and add the settings for the API discovery service.

  1. Edit the `ManagementCluster` CR and add the following definition for the API discovery service. Append the API discovery definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       discovery:
         enabled: true
         proxyCollectorEnabled: true
     ```

  2. Apply the updated CR by running the following command as part of the standard Management subsystem installation (see Installing the management subsystem for details):

     ```
     kubectl apply -f management_cr.yaml -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
     The API discovery service will be enabled with the Management subsystem.

  3. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `api-discovery` pods are shown in the list of returned values, and the `ManagementCluster` has completed with a `READY` status of `True`, and the `SUMMARY` reports that the services are online, for example `1/1`.

- **Enabling the API discovery service as part of an existing deployment**
  Edit the deployed CR for the Management subsystem and add the settings for the API discovery service.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, append the API discovery definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       discovery:
         enabled: true
         proxyCollectorEnabled: true
     ```

  4. Save the update.
     The API discovery service is enabled in the Management subsystem.

  5. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `api-discovery` pods are shown in the list of returned values, and the `ManagementCluster` has completed with a `READY` status of `True`, and the `SUMMARY` reports that the services are online, for example `1/1`.

- **Disabling the API discovery service**
  Edit the deployed CR for the Management subsystem and update the settings for the API discovery service.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

```
kubectl edit managementcluster <management-cr-name> -n <management_namespace>
```

Where:

- *management-cr-name* is the name of the deployed CR for the Management subsystem.
- *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.

3. In the editor, change the API discovery definition to `enabled: false`.

```
spec:
  ...
  discovery:
    enabled: false
    proxyCollectorEnabled: false
```

4. Save the update.
   The API discovery service is disabled in the Management subsystem.

Results

Note that when the API discovery service is enabled, there are a number of new deployments, jobs, and pods in the `ManagementCluster` namespace. These Kubernetes API discovery resources have names that contain `api-discovery`. For example:

```
kubectl get pods -n apic | grep discovery
management-api-discovery-gw-proxy-collector-8d8bdfbdf51fbj   1/1     Running     0          88m
management-api-discovery-gw-proxy-collector-8d8bdfbdf67qqz   1/1     Running     0          88m
management-api-discovery-gw-proxy-collector-8d8bdfbdfzrhkv   1/1     Running     0          88m
management-api-discovery-service-f7dc497d8-gc7dn             1/1     Running     0          89m
management-api-discovery-service-f7dc497d8-pd877             1/1     Running     0          89m
management-api-discovery-service-f7dc497d8-shzm9             1/1     Running     0          89m
management-api-discovery-ui-5549df59d9-b4fks                 1/1     Running     0          88m
management-api-discovery-ui-5549df59d9-gjqmx                 1/1     Running     0          88m
management-api-discovery-ui-5549df59d9-pjvsx                 1/1     Running     0          88m
management-up-api-discovery-service-data-populate-0-tvxbvs   0/1     Completed   0          90m
management-up-api-discovery-service-schema-0-to-2-mrs8d      0/1     Completed   0          90m
```

Enabling governance on Kubernetes

You can optionally configure governance in IBM® API Connect on a Kubernetes, OpenShift, or IBM Cloud Pak for Integration deployment by enabling the governance service.

About this task

The governance service is an optional add-on to API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process.

Note:

- These instructions apply only to Kubernetes, OpenShift, and IBM Cloud Pak for Integration installations. For VMware installations, see Enabling governance on VMware.
- Governance rulesets cannot be added to your deployment until the governance service is enabled.
- If you're using a two data center disaster recovery (2DCDR) deployment, the governance service must be enabled on both the active and warm-standby centers. Enable the service on the warm-standby data center first, and then the active center.

To enable or disable the governance service, you must configure the Management subsystem custom resource (CR) file. See the following instructions:

- **Enabling the governance service as part of a new deployment**
- **Enabling the governance service as part of an existing deployment**
- **Disabling the governance service**

After the governance service is enabled, governance resources can be created. For more information, see Configuring governance in the Cloud Manager, and Configuring governance in the API Manager.

Procedure

- **Enabling the governance service as part of a new deployment**
  Edit the CR file for the Management subsystem and add the settings for the governance service.

  1. Edit the `ManagementCluster` CR and add the following definition for the governance service. Append the governance definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       governance:
         enabled: true
     ```

  2. Apply the updated CR by running the following command as part of the standard Management subsystem installation (see Installing the management subsystem for details):

     ```
     kubectl apply -f management_cr.yaml -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
     The governance service will be enabled with the Management subsystem.

  3. You can monitor your Kubernetes deployments by running the following command:

```
kubectl get deployments -n <management_namespace>
```

The installation is complete when the `management-compliance` pods are shown in the list of returned values.

- **Enabling the governance service as part of an existing deployment**
  Edit the deployed CR for the Management subsystem and add the settings for the governance service.
  Note: When you enable governance in the existing deployment, the UI requires approximately 15 minutes to restart the pod and display the new feature. There will be an outage in the UI during this period.
  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, append the governance definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       governance:
         enabled: true
     ```

  4. Save the update.
     The governance service is enabled in the Management subsystem.
  5. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `management-compliance` pods are shown in the list of returned values.
- **Disabling the governance service**
  Edit the deployed CR for the Management subsystem and update the settings for the governance service.
  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, change the governance definition to `enabled: false`.

     ```
     spec:
       ...
       governance:
         enabled: false
     ```

  4. Save the update.
     The governance service is disabled in the Management subsystem.

Results

Note that when the governance service is enabled, there are a number of new deployments, jobs, and pods in the `ManagementCluster` namespace. These Kubernetes governance resources have names containing either `compliance-service` or `compliance-ui`. For example:

```
kubectl get pods -n apic | grep compliance
management-compliance-service-f6cdf95fc-t4qkx                     1/1     Running     0          127m
management-compliance-ui-59897fcc4-zm25v                          1/1     Running     0          126m
management-up-compliance-service-data-populate-0-to-1-t2f4d       0/1     Completed   1          132m
management-up-compliance-service-schema-0-to-1-21kqq              0/1     Completed   0
```

Configuring monetization on Kubernetes

You can optionally configure monetization in API Connect on a Kubernetes deployment by enabling the billing microservice.

About this task

API Connect includes a subscription billing microservice that allows API providers to define pricing plans in their API Products, and monetize their API offerings. If a Product contains a pricing plan, API Consumers must enter their payment information into the Developer Portal before they can subscribe to that plan. API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Note:

- These instructions apply only to Kubernetes installations. For VMware installations, see Configuring monetization on VMware.
- To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements and Firewall requirements on VMware for more information about this requirement.
- Provider organizations cannot add any billing integrations until the billing microservice is enabled.
- After provider organizations have added billing integrations, the billing microservice must not be disabled.

To enable or disable the billing microservice, you must configure the Management subsystem custom resource (CR) file. See the following instructions:

- **Enabling the billing microservice as part of a new deployment**
- **Enabling the billing microservice as part of an existing deployment**
- **Disabling the billing microservice**

Procedure

- **Enabling the billing microservice as part of a new deployment**
  Edit the CR file for the Management subsystem and add the settings for the billing microservice.

  1. Edit the `ManagementCluster` CR and add the following definition for the billing microservice. Append the billing definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       billing:
         enabled: true
     ```

  2. Apply the updated CR by running the following command as part of the standard Management subsystem installation (see Installing the management subsystem for details):

     ```
     kubectl apply -f management_cr.yaml -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
     The billing microservice will be enabled with the Management subsystem.

  3. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `management-billing` pod is shown in the list of returned values.

  After the billing microservice is enabled, provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see Monetizing your Products.

- **Enabling the billing microservice as part of an existing deployment**
  Edit the deployed CR for the Management subsystem and add the settings for the billing microservice.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:
     - *management-cr-name* is the name of the deployed CR for the Management subsystem.
     - *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  3. In the editor, append the billing definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.

     ```
     spec:
       ...
       billing:
         enabled: true
     ```

  4. Save the update.
     The billing microservice is enabled in the Management subsystem.

  5. You can monitor your Kubernetes deployments by running the following command:

     ```
     kubectl get deployments -n <management_namespace>
     ```

     The installation is complete when the `management-billing` pod is shown in the list of returned values.

  After the billing microservice is enabled, provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see Monetizing your Products.

- **Disabling the billing microservice**
  Important: After provider organizations have added billing integrations, the billing microservice must not be disabled.
  Edit the deployed CR for the Management subsystem and update the settings for the billing microservice.

  1. Retrieve the name of the deployed CR for the Management subsystem by running the following command:

     ```
     kubectl get managementcluster -n <management_namespace>
     ```

     Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
  2. Edit the deployed CR by running the following command:

     ```
     kubectl edit managementcluster <management-cr-name> -n <management_namespace>
     ```

     Where:

- *management-cr-name* is the name of the deployed CR for the Management subsystem.
- *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.

3. In the editor, change the billing definition to `enabled: false`.

```
spec:
  ...
  billing:
    enabled: false
```

4. Save the update.
   The billing microservice is disabled in the Management subsystem.

Enabling billing feature on OpenShift and Cloud Pak for Integration

You can optionally configure monetization in API Connect on Red Hat OpenShift and IBM® Cloud Pak for Integration by enabling the billing feature.

About this task

API Connect includes a billing feature that allows API providers to define pricing plans in their API Products, and monetize their API offerings. If a Product contains a pricing plan, API Consumers must enter their payment information into the Developer Portal before they can subscribe to that plan.

Procedure

- Enabling billing feature on Cloud Pak for Integration
  1. Log in to the Platform UI.
  2. Locate the instance for which you want to enable the billing feature.
  3. Click the options menu icon ⋮ alongside the required instance.
  4. Click Edit.
  5. Toggle the Advanced settings slider.
  6. Click Management subsystem.
  7. Locate the Billing option.
  8. Click the Enabled (optional) checkbox.
  9. Click Save.
- Enabling billing feature on Red Hat OpenShift
  1. Log in to the Red Hat OpenShift web console.
  2. Click Installed operators.
  3. Locate the namespace (project) where you installed API Connect:
     - If you installed the API Connect operator in all namespaces, select openshift-operators
     - If you installed the API Connect operator in a single namespace, select specific project
  4. Select the API Connect Connect operator.
  5. Select all instances for an overview of all operands in your API Connect namespace.
  6. Locate the instance for which you want to enable the billing feature.
  7. Click the options menu icon ⋮ alongside the required instance.
  8. Click Edit.
  9. Click Advanced configuration.
  10. Click Management subsystem.
  11. Click Advanced configuration.
  12. Click Billing.
  13. Click the Enabled (optional) checkbox.
  14. Click Save.

Restarting the Management subsystem pods

How to restart Management subsystem pods in your API Connect deployment.

Procedure

1. Determine your deployment name by running the following command:

   ```
   kubectl -n <namespace> get deployment | grep <management CR>
   ```

   where
   - *<namespace>* is the namespace where the management subsystem is installed.
   - *<management CR>* is the name your management subsystem CR.
2. Restart pods by running the `kubectl` commands shown in Table 1.
   Use the deployment name that you obtained in step 1.

Table 1. Management pods and the commands to restart them

Pod	Restart command
`management-analytics-proxy`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`
`management-apim`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>` A manual restart is not needed when the certificate is updated.
`management-client-downloads-server`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>` A manual restart is not needed when the certificate is updated.
`management-atm-api`	`kubectl rollout restart deployment/deployment_name -n <namespace>`
`management-atm-ui`	`kubectl rollout restart deployment/deployment_name -n <namespace>`
`management-juhu`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`
`management-ldap`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>` A manual restart is not needed when the certificate is updated.
`management-lur`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>` A manual restart is not needed when the certificate is updated.
`management-natscluster`	Run for each `natscluster` pod, one at a time: `kubectl exec` *`management-natscluster-n`* `-- bash -c "kill -HUP 1"` A manual restart is not needed when the certificate is updated.
`edb-operator`	`kubectl rollout restart deployment edb-operator -n <namespace>`
`management-portal-proxy`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>` A manual restart is not needed when the certificate is updated.
`management-taskmanager`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>` A manual restart is not needed when the certificate is updated.
`management-tunnel`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`
`management-ui`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`
`management-analytics-ui`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`
`management-`*`remote-sitename`*`-postgres`	`kubectl rollout restart deployment/`*`deployment_name`* `-n <namespace>`

3. Verify that all management pods are ready by running the following command:

   `kubectl -n <namespace> get pods`

   where *<namespace>* is the namespace where the management subsystem is installed.

   The restart is complete when all pods are `Running` and `Ready`.

Disabling the PDB for the management EDB database

Disable `PodDisruptionBudget` (PDB) for replica management subsystems.

About this task

Some maintenance scenarios require that Postgres be shutdown. In such cases, PDB can prevents this shutdown to keep the system available. For node maintenance activities, you can disable the PDB by setting the `enablePDB` flag to `false`.

Procedure

1. Before making any changes, verify the current PDB by running the following command: `kubectl get pdb`. The system displays the following output:
   Note: Depending on whether you have one or three node deployment, the PDBs appear differently.
   - For a single-node deployment, you will see only the following primary PDB:

     ```
     NAME                        MIN AVAILABLE   MAX UNAVAILABLE   ALLOWED DISRUPTIONS   AGE
     abc-management-site1-db-primary   1               N/A               0                     54d
     ```

   - For a multi-node (three-node) deployment, you will see both primary and secondary PDBs:

     ```
     NAME                        MIN AVAILABLE   MAX UNAVAILABLE   ALLOWED DISRUPTIONS   AGE
     management-c9cbf3f4-db            1               N/A               1                     73m
     management-c9cbf3f4-db-primary    1               N/A               0                     73m
     ```

2. Edit the management Custom Resource (CR) using the following command: `kubectl edit mgmt <mgmt-cr-name>` or the top-level CR using the command: `kubectl edit apic <apic-cluster-name>`, whichever is deployed in your environment.
   For the management CR, run the following command to override the template:

```
template:
  - name: edb-cluster
    enablePDB: false
```

For top-level CR, run the following command to override the template:

```
template:
  - name: mgmt-edb-cluster
    enablePDB: false
```

3. Once template override is added, run the following command to verify that the PDB is disabled: `kubectl -n <namespace> / oc get pdb`.
   Note: Ensure to set `enable PDB` flag to `true` post maintenance activities.

Advanced configuration for Postgres components on Kubernetes V10.0.7.0 and later

This section describes the default affinity, nodeSelector, and toleration settings of EDB Postgres and Operator pods and examples of how to customize them.

EDB Postgres pods

Postures pods default configuration

The following are the Postgres pods default:
Note: The following are examples only and it can vary from your pod name.
The following are the rules for Affinity:

- Required: Repels its own pods within the same hostname.
- Preferred: Repels edb-operator pods within the same hostname.

```
spec:
  affinity:
    podAntiAffinity:
      preferredDuringSchedulingIgnoredDuringExecution:
      - podAffinityTerm:
          labelSelector:
            matchExpressions:
            - key: app.kubernetes.io/name
              operator: In
              values:
              - cloud-native-postgresql
          namespaceSelector: {}
          topologyKey: kubernetes.io/hostname
        weight: 100
      requiredDuringSchedulingIgnoredDuringExecution:
      - labelSelector:
          matchExpressions:
          - key: k8s.enterprisedb.io/cluster
            operator: In
            values:
            - management-b6d7a59d-db
        topologyKey: kubernetes.io/hostname
```

Tolerations:

```
tolerations:
  - effect: NoExecute
    key: node.kubernetes.io/not-ready
    operator: Exists
    tolerationSeconds: 300
  - effect: NoExecute
    key: node.kubernetes.io/unreachable
    operator: Exists
    tolerationSeconds: 300
```

NodeSelector: None

Customization

To customize affinity (which can be nodeAffinity, podAffinity, podAntiAffinity),nodeSelector, or toleration, you need to add a template in the spec section of the ManagementCluster. This template will help you set the desired rules for pod placement in your Kubernetes cluster.

```
spec:
  template:
  - name: edb-cluster
    affinity:
      nodeAffinity:
        <your settings>
      podAffinity:
        <your settings>
      podAntiAffinity:
        <your settings>
    nodeSelector:
      <your settings>
    tolerations:
      <your settings>
```

To customize a deployment using API ConnectCluster CR for OpenShift or CP4i deployments, you can use the following template:

```
spec:
  template:
# management services must be specified with prefix "mgmt-"
  - name: mgmt-edb-cluster
    affinity:
      nodeAffinity:
         <your settings>
      podAffinity:
         <your settings>
      podAntiAffinity:
         <your settings>
    nodeSelector:
      <your settings>
    tolerations:
      <your settings>
```

EDB operator pods

Operator pods default configuration

The following are the rules for Affinity:

- Preferred: Repels its own pods within the same hostname.
- Preferred: Repels Postgres pods with podRole=instance (all Postgres master and replica pods) within the same hostname.

```
spec:
  affinity:
    podAntiAffinity:
      preferredDuringSchedulingIgnoredDuringExecution:
      - podAffinityTerm:
          labelSelector:
            matchExpressions:
            - key: app.kubernetes.io/instance
              operator: In
              values:
              - management
            - key: app.kubernetes.io/managed-by
              operator: In
              values:
              - ibm-apiconnect
            - key: app.kubernetes.io/name
              operator: In
              values:
              - cloud-native-postgresql
          topologyKey: kubernetes.io/hostname
        weight: 100
      - podAffinityTerm:
          labelSelector:
            matchExpressions:
            - key: app.kubernetes.io/instance
              operator: In
              values:
              - management
            - key: app.kubernetes.io/managed-by
              operator: In
              values:
              - ibm-apiconnect
            - key: k8s.enterprisedb.io/podRole
              operator: In
              values:
              - instance
          namespaceSelector: {}
          topologyKey: kubernetes.io/hostname
        weight: 100
```

Tolerations:

```
tolerations:
  - effect: NoExecute
    key: node.kubernetes.io/not-ready
    operator: Exists
    tolerationSeconds: 300
  - effect: NoExecute
    key: node.kubernetes.io/unreachable
    operator: Exists
    tolerationSeconds: 300
```

NodeSelector: None

Advanced configuration for the analytics subsystem

Specify advanced configuration for the analytics subsystem on Kubernetes, OpenShift, or Cloud Pak for Integration.

To manage advanced analytics features, see: Advanced configuration for the analytics subsystem.

Advanced configuration for the gateway subsystem

Specify advanced configuration for the gateway subsystem.

See:

- **Customizing a DataPower deployment**
  Update the `GatewayCluster` CR to configure `DataPowerService` APIs to customize your DataPower deployment.
- **Updating the gateway password, secrets, and certificates**
  How to update the gateway administrator password, the client_secret, the peering secret, and the invocation endpoint certificate.
- **Overriding the default DataPower image, version, and license**
  Update the `GatewayCluster` CR to override the image, version, and license information for the Gateway subsystem.
- **Overriding pod CPU and memory settings**
  Use template overrides to set a higher CPU and memory for your gateway pod.
- **Enabling autoscaling of gateway pods**
  Enable autoscaling of gateway pods to ensure high availability of DataPower pods.
- **Configuring rate limits on the gateway nodes**
  Create an env.yaml file on each Gateway node to configure the default rate limit.
- **Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment**
  In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.
- **Overriding DataPowerService spec properties**
  Use the `dataPowerServiceSpecOverride` to configure `DataPowerService` spec-level properties.

Customizing a DataPower deployment

Update the `GatewayCluster` CR to configure `DataPowerService` APIs to customize your DataPower deployment.

You can set the following properties in the CR. Note that each `GatewayCluster` CR property has a corresponding `DataPowerService` API. Refer to the DataPower Operator documentation link for each property:
Note: If you are using a top-level CR (`APIConnectCluster`), ensure that the `spec.gateway` section is included. If it is missing, add the `spec.gateway` section first before adding the required property within it.

Table 1. Mapping of `GatewayCluster` properties to `DataPowerService` properties

GatewayCluster property	DataPowerService property	DataPowerService API Docs
`additionalDomainConfig`	`domains`	domains For domain configuration, see also: • Guides: Domain Configuration • Features: Configuration Management
`additionalExtraExe`	`extraExe`	extraExe
`additionalInitCmds`	`initCmds`	initCmds
`lifecycle`	`lifecycle`	lifecycle
`healthcheck`	`healthcheck`	healthcheck
`readinessTimeoutSeconds`	`readinessTimeoutSeconds`	readinessTimeoutSeconds
`hostAliases`	`hostAliases`	hostAliases

Examples of how to add the DataPower service properties to a `GatewayCluster` CR, in an API Connect deployment on native Kubernetes:

- Adding `additionalDomainConfig`:

```
spec:
  additionalDomainConfig:
  - name: "default"
    certs:
    - certType: "usrcerts"
      secret: "default-cert"
    - certType: "sharedcerts"
      secret: "shared-cert"
    dpApp:
      config:
      - "default-config"
      local:
      - "default-local"
```

- Extending the `apiconnect` domain:

```
spec:
  additionalDomainConfig:
  - name: "apiconnect"
    dpApp:
      config:
      - "custom-apiconnect-config"
      local:
      - "custom-apiconnect-local"
```

Updating the gateway password, secrets, and certificates

How to update the gateway administrator password, the client_secret, the peering secret, and the invocation endpoint certificate.

- **Changing the gateway administrator password**
  Change the gateway administrator password by updating the CR and reinstalling the subsystem.
- **Changing the gateway client secret**
  The gateway subsystem receives its `client_secret` from the management subsystem.
- **Updating the gateway peering certificate**
  Update the certificate that secures communication between gateways in your API Connect deployment.
- **Updating the gateway director and invocation endpoint profiles**
  Update the TLS profile that secures communications with the gateway subsystem in your API Connect deployment.

Changing the gateway administrator password

Change the gateway administrator password by updating the CR and reinstalling the subsystem.

About this task

Updating the administrator password for the gateway subsystem requires no measurable reduction in API enforcement performance (gateways remain "up"); however, services such as SNMP will experience a disconnect until the password is updated on all pods.

Procedure

1. Get the name of the secret that is used in the gateway CR.
   a. Run the following command to get the gateway's `secretName`:

      ```
      kubectl -n <namespace> get gatewaycluster <gw-cluster-name> -o yaml
      ```

      where *<namespace>* is the namespace where you installed the gateway subsystem, and *<gw-cluster-name>* is the name of the gateway cluster.

      In the CR, the gateway's `secretName` is in the `adminUser` section.

   b. Note down the secret name for use in a later step.
2. Scale the *<gw-cluster-name>* to 0 pods.
   a. Using the following example as a guide, set `replicaCount=0` for the *<gw-cluster-name>*.

      ```
      kubectl -n <namespace> patch gatewaycluster <gw-cluster-name> --type json -p='[{"op": "add", "path":
      "/spec/replicaCount", "value": 0 }]'
      ```

   b. Validate that `statefulset READY = 0/0`.
      Run the following command:

      ```
      kubectl  -n <namespace> get statefulset <gw-cluster-name>
      ```

      A successful response looks like the following example:

      ```
      NAME   READY   AGE
      gwv6   0/0     18h
      ```

3. Update the gateway's secret.
   a. Run the following command to edit the gateway's `secretName`:

      ```
      kubectl -n <namespace> edit secret secretName
      ```

   b. Change the value of `.data.password` to be the base64-encoded value of a new password. The new password can be any string you want but you must encode it to base64.
4. Scale the gateway back up to the correct number of pods.
   a. Using the following example as a guide, set `replicaCount=3` for *<gw-cluster-name>*.

      ```
      kubectl -n <namespace> patch gatewaycluster <gw-cluster-name> --type json -p='[{"op": "add", "path":
      "/spec/replicaCount", "value": 3 }]'
      ```

   b. Validate that `statefulset READY = 3/3` (this step might take few minutes to complete).
      Run the following command:

      ```
      kubectl  -n <namespace> get statefulset <gw-cluster-name>
      ```

      A successful response looks like the following example:

      ```
      NAME   READY   AGE
      gwv6   3/3     18h
      ```

5. Verify that the gateway subsystem is fully updated.
   Run the following command, replacing *<namespace>* with the appropriate namespace.

   ```
   kubectl -n namespace get GatewayCluster
   ```

   The update is complete when the `READY` status is `True`, and the `SUMMARY` reports that all services are online (`2/2`) for all the Gateway subsystems that were updated. Example:

   ```
   NAME   READY   SUMMARY   VERSION    RECONCILED VERSION   AGE
   gwv5   True    2/2       10.0.8.0   10.0.8.0-1219        7m31s
   gwv6   True    2/2       10.0.8.0   10.0.8.0-1219        7m32s
   ```

Changing the gateway client secret

The gateway subsystem receives its **client_secret** from the management subsystem.

About this task

If you changed the **client_secret** on the management subsystem, force a dynamic reconfiguration and reregistration (DRR) as explained in How can I force re-population of the configuration data?. On completion, the gateway subsystem uses the new **client_secret** in its communications with the management subsystem.

Updating the gateway peering certificate

Update the certificate that secures communication between gateways in your API Connect deployment.

About this task

This task covers updating the gateway peering certificate, which is used to secure communication between gateway cluster members, on Kubernetes and OpenShift deployments.
Note: For gateway appliance deployments, you must manually update the Gateway Peering Identification Credential and Validation Credential objects.
The gateway peering certificate is stored in a Kubernetes secret. To update the certificate, delete this secret so that the cert-manager creates a new secret that contains a new peering certificate.

Important: If you are updating the peering certificate because you updated the ingress-ca certificate, then the update causes a gateway outage and the gateway pods must be manually restarted.

Procedure

1. Determine the name of your gateway cluster CR:

   ```
   kubectl get GatewayCluster
   ```

2. Determine the name of the gateway peering secret:

   ```
   kubectl get -o yaml gatewayCluster <gateway cluster>
   ```

   where *<gateway cluster>* is the name that you obtained in step 1.

   The name of the secret is defined in **spec.apicGatewayPeeringTLS.secretName**, for example:

   ```
   spec:
     ...
     apicGatewayPeeringTLS:
       secretName: apic-ocp-gw-peer
   ```

3. Delete the gateway peering secret:

   ```
   kubectl delete secret <gateway peering secret>
   ```

   where *<gateway peering secret>* is the name that you identified in step 2.
   A new gateway peering secret is created and a rollout restart of the gateway statefulset is triggered.

4. If the **ingress-ca** certificate was also updated, then the rollout restart does not complete, and you must restart the gateway pods manually:

   ```
   kubectl delete pod <gw pod1> <gw pod2> <gw pod3>
   ```

5. To verify the update, check the age of the gateway peering secret to confirm a new secret was created:

   ```
   kubectl get secret <gateway peering secret>
   ```

   ```
   NAME                        TYPE                DATA   AGE
   <gateway peering secret>    kubernetes.io/tls   3      30s
   ```

Updating the gateway director and invocation endpoint profiles

Update the TLS profile that secures communications with the gateway subsystem in your API Connect deployment.

Update the gateway API invocation certificate and the gateway director client certificate in the TLS profiles that are configured for your gateway service in the Cloud Manager UI. See Registering a gateway service and TLS profiles overview.

To update the gateway director server certificate on Kubernetes deployments, update the Kubernetes secret: **gwv6-manager-endpoint/gw-gateway-manager**.

Overriding the default DataPower image, version, and license

Update the **GatewayCluster** CR to override the image, version, and license information for the Gateway subsystem.

Procedure

To override these settings in the CR, add a `spec.dataPowerOverride` section as shown in the following example:

- If you deployed the gateway subsystem on Kubernetes, or if you deployed the individual gateway subsystem on OpenShift, add the override to the `spec` section of the Gateway CR:

```
spec:
   dataPowerOverride:
     image: customregistry.com/custom-image-datapower:10.6.0.4
     version: 10.6.0.4
     license: X-XXXX-XXXXXX
```

- If you deployed all API Connect subsystems at once on OpenShift using the top-level `apiconnectcluster` CR, add the override to the `spec.gateway` section:

```
spec:
  gateway:
    dataPowerOverride:
      image: customregistry.com/custom-image-datapower:10.6.0.4
      version: 10.6.0.4
      license: X-XXXX-XXXXXX
```

Overriding pod CPU and memory settings

Use template overrides to set a higher CPU and memory for your gateway pod.

About this task

Important: The recommended method to increase the resources for your API Connect deployment is to change deployment profile:

- Changing deployment profiles on Kubernetes and OpenShift
- Changing deployment profiles on OpenShift top-level CR
- Changing the deployment profile on Cloud Pak for Integration

Increasing the number of CPUs impacts API Connect licensing. See Deployment and component profiles.

Note: For OpenShift users: The example steps in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR you must edit the `APIConnectCluster` CR (the top-level CR), instead of directly editing the subsystem CRs. If the subsystem section is not included in the top-level CR, copy and paste the section from the subsystem CR to the `APIConnectCluster` CR.

Procedure

1. Edit the gateway CR:

   ```
   kubectl edit gw
   ```

2. Add a `spec.template` section with the new memory and CPU settings. For example:

   ```
   template:
   - name: datapower
     containers:
     - name: gateway
       resources:
         limits:
           cpu: 4
           memory:  12Gi
         requests:
           cpu: 2
           memory: 10Gi
   ```

   Note:
   The default memory limit and request is 8Gi. The memory limit must always be greater than or equal to the memory request.

   For information about overriding other properties, see Overriding the default DataPower image, version, and license.

   The template override mechanism is specific only to the CPU and memory values, and cannot be used for other resource requests in the DataPower Gateway CR.

Enabling autoscaling of gateway pods

Enable autoscaling of gateway pods to ensure high availability of DataPower pods.

Autoscaling enables the gateway deployment to scale dynamically, either vertically or horizontally.

It is not possible to use both horizontal and vertical pod scaling simultaneously. You must configure either `HPA` (for horizontal scaling) or `VPA` (for vertical scaling) as scaling method.

- To enable HPA, add the following fields to the CR:
  In OpenShift or Cloud Pak for Integration, add the fields to the `spec.gateway` section of the API Connect Cluster CR.

```
podAutoScaling:
  hpa:
    maxReplicas: 5
    minReplicas: 3
    targetCPUUtilizationPercentage: 90
    targetMemoryUtilizationPercentage: 80
  method: HPA
```

- To enable VPA, add the following fields to the CR:
  In OpenShift or Cloud Pak for Integration, add the fields to the **spec.gateway** section of the API Connect Cluster CR.

```
podAutoScaling:
  method: VPA
  vpa:
    maxAllowedCPU: 4
    maxAllowedMemory: 16G
```

Note that the values shown in the CR entries are just examples.

Table 1. Autoscaling configuration settings

Setting	Description
method	Specifies either Horizontal Pod Autoscaling or Vertical Pod Autoscaling Value must be either **HPA** or **VPA**. To disable autoscaling, leave **method** blank or omit the **podAutoScaling:** section from the CR.
maxReplicas	HPA. Maximum pods that can be scaled up to by the horizontal pod autoscaler. Must be a value greater than **minReplicas**.
minReplicas	HPA. Minimum pods that can be scaled down to by the horizontal pod autoscaler.
targetCPUUtilizationPercentage:	HPA. Percent threshold on average CPU usage by pods for triggering horizontal scaling.
targetMemoryUtilizationPercentage	HPA. Percent threshold on average memory usage by pods for triggering horizontal scaling.
maxAllowedCPU	VPA. Maximum value for CPU resource that can be assigned to a DataPower container when scaling vertically. Minimum value is set from **DataPowerRequestsSpec.ResourceCPU**
maxAllowedMemory	VPA. Maximum amount of memory that can be assigned to a DataPower container when scaling vertically. Minimum value is set from **DataPowerRequestsSpec.ResourceMemory**

Note:
DataPower Gateway supports long-lived connections such as such as GraphQL subscriptions or other websockets connections. These long-lived connections might not be preserved when pods are scaled down based on defined CPU or memory thresholds. Workloads with long-lived connections are more vulnerable to failed API transactions when auto-scaling is occurring.

To learn more about HPA and VPA autoscaling, see

- https://ibm.github.io/datapower-operator-doc/features/pod-auto-scaling/
- https://ibm.github.io/datapower-operator-doc/apis/datapowerservice/v1beta3#podautoscaling

Configuring rate limits on the gateway nodes

Create an env.yaml file on each Gateway node to configure the default rate limit.

The Gateway uses scale limits (instead of strict limits) by default to enforce rate limits. This improves the gateway's performance by providing the ability to handle large amounts of rate-limited traffic.

1. To configure the rate limit, create a file called env.yaml with the settings provided in Table 1:

Table 1. Rate limit settings

Setting	Type	Default	Optoins	Comments
USE_RATE_LIMIT_DEFINITION	boolean	**true**	• **true** Use scale limits • **false** Use strict limits	Determines the type of rate limiting to use on the Gateway node.
RATE_LIMIT_UPDATE_MODE	enumerated	**prior**	• **none**No limits in a plan are incremented after a limit is reached. • **all** All limits in a plan are incremented after a limit is reached. • **prior** Retains the behavior from pre-V10 releases: When the plan rate limit is reached, all limits in the plan that are sorted before that plan limit will be incremented.	Determines how the counts within a plan are incremented when a rate limit is hit. Applies only to scale limits.

Setting	Type	Default	Optoins	Comments
`RATE_LIMIT_SORT_BY_DURATION`	boolean	`true`	• `true` Sort the rate limits by duration. • `false` Revert to the previous sort order.	Determines the sort order for rate limits in a plan, which in turn determines the sequence in which they are applied.
`RATE_LIMIT_USE_OFFSET`	boolean	`false`	• `true` Prevent all rate limit counts for an interval from being reset at the same time. • `false` Allow all rate limit counts for an interval to be reset at the same time.	Allow or prevent all of the rate limit counts for an interval from being reset at the same time. Preventing the simultaneous reset protects backends from being saturated with requests by resetting the counts for different subscribers of a plan at different points with in the interval. Applies only to scale limits.
`RATE_LIMIT_DEFINITION_RESPONSE_HEADERS`	boolean	`true`	• `true` Show the `x-rate-limit` headers. • `false` Hide the `x-rate-limit` headers.	Show or hide the `x-rate-limit` headers in an API response. Applies only to scale limits.

2. Save the file in the local:/ directory on the Gateway node so that the file persists on reboots of both physical and virtual machines. The settings apply only to the node where the file is stored, so each node in the Gateway cluster requires its own copy of the file.

Dynamically re-registering and reconfiguring a Gateway service in a Kubernetes deployment

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

If a Gateway service is not configured properly for resiliency and is restarted, the gateways in the Gateway service will lose the configuration from the Management server. Configuration data from the Management server is maintained on the gateway service according to the gateway peering configuration on the gateways.

Preventing the loss of configuration data

For high availability in production environments, use a minimum of three gateways in the Gateway service.

Forcing re-population of the configuration data

To repopulate the configuration data, complete the steps in the following section to trigger an outage-less DRR.

Triggering an outage-less DRR

To force a Dynamic Reregistration and Reconfiguration across a peer group from within the gateway service without requiring a restart, complete the following steps using the CLI. This process flushes the primary peering object configured for the **`apic-gw-service`**. This task can only be performed with CLI, and requires the default admin ID for running the **`diag`** command.

1. Access the gateway service:
   - For a virtual gateway, run the following command to access the DataPower CLI:

     ```
     kubectl attach -it <pod_name>
     ```

   - For a physical gateway, use **`ssh`** to connect to the gateway service.
2. Switch to the API Connect application:

   ```
   switch <APIC_APP_DOMAIN>
   ```

3. Show the current gateway-peering-status:

   ```
   show gateway-peering-status
   ```

4. If the server that you connected to is not primary for the apic-gw-service gateway-peering object, force this server to become primary:

   ```
   config; gateway-peering-switch-primary <gateway-peering-name-for-apic-gw-service>;
   ```

5. Flush the apic-gw-service gateway-peering object:

   ```
   diag; gateway-peering-flush <gateway-peering-name-for-apic-gw-service>; exit
   ```

   When prompted, confirm the operation.

6. Disable and then re-enable the apic-gw-service object for every member of the gateway service:

```
config; apic-gw-service; admin-state disabled; exit
apic-gw-service; admin-state enabled; exit; exit
```

7. Confirm that the apic-gw-service was flushed and is now waiting for gateway service registration:
   Look in the debug log target for the apic-gw-service, located in logtemp:/// and check for a message similar to the following example:

   ```
   20200618T232339.332Z [0x88e000d7][apic-gw-service][notice]
   apic-gw-service(default): tid(2653): Waiting for gateway service registration.
   ```

   The DRR will be triggered by the next arrival of a webhook event. The Management server sends a heartbeat to the gateway at five-minute intervals, prompting the gateway to check whether it has lost its configuration and if so, trigger a DRR. In addition, if the Management server has previously marked a Catalog or cloud as being unavailable for a particular gateway service, a successful heartbeat triggers synchronization for that Catalog or cloud on that gateway service.

8. If you attached to a virtual gateway, you can detach by pressing Ctrl+P and then pressing Ctrl+Q.
9. (Optional) Force a BAU webhook event to be sent from API Manager to trigger the DRR:
   If you do not want to wait for the Management server to send a heartbeat, you can trigger the DRR manually by completing the following steps:

   a. Open the API Manager.
   b. Open the Catalog.
   c. Click Settings > Edit.
   d. Update the Summary field with some text so that it is modified.
   e. Click Save.

When the event is received, the DRR is initiated.

Confirm that DRR is complete by testing your APIs. You can also use the health check API.

Overriding `DataPowerService` spec properties

Use the **`dataPowerServiceSpecOverride`** to configure **`DataPowerService`** spec-level properties.

Configure the **`spec.dataPowerServiceSpecOverride`** section in your gateway CR to set **`DataPowerService`** properties.

1. Edit your gateway CR:

   ```
   kubectl edit GatewayCluster
   ```

2. Add the **`dataPowerServiceSpecOverride`** section to the **`spec`** section (if it does not exist), and configure the properties as required.

Sample configurations:

- Specify a new environment:

  ```
  spec:
    dataPowerServiceSpecOverride:
      env:
      - name: TEST_ENV
        value: "true"
  ```

- Add new **`initCmds`**:

  ```
  spec:
    dataPowerServiceSpecOverride:
      initCmds:
      - ls -al /opt/ibm/datapower/drouter/config
  ```

If you are using the OpenShift top-level CR, then add the **`dataPowerServiceSpecOverride`** section to **`spec.gateway`**.

Advanced configuration for the portal subsystem

- **Updating portal keys and secrets**
  Update the database passwords, keys, and the **`client_secret`** values for your portal subsystem.

Updating portal keys and secrets

Update the database passwords, keys, and the **`client_secret`** values for your portal subsystem.

- **Changing the secret for portal data and system tools**
  Replace the encryption key that generates the secret used for securing the database and system tools that are used by the portal subsystem.
- **Changing the portal client_secret**
  Change the **`client_secret`** for the portal subsystem to keep it in sync with the management subsystem.

Changing the secret for portal data and system tools

Replace the encryption key that generates the secret used for securing the database and system tools that are used by the portal subsystem.

Before you begin

If you are using a stand-alone, single data center deployment, you can update the encryption key with the PortalSecretRotation CR, as explained in Renewing the portal-ca with the PortalSecretRotation CR. The PortalSecretRotation CR is not supported for a two data center configuration or a Cloud Pak for Integration deployment, so you must update the key manually as explained in the following steps.

About this task

The portal subsystem uses a database plus several system tools to manage storage, hot backups, and cluster synchronization. The following services are all secured with the secret that is generated by the portal CR during installation:

- MySQL root account for each portal site
- Csync2 cluster synchronization service

Updating the portal-encryption-secret will make the following changes to your deployment:

- Change the root MySQL password
- Generate a new, site-specific MySQL password for each site
- Generate a new csync2 cluster key
- Re-encrypt all client_ids and client_secrets in the portal database

If you need to change the secret, the update is applied to all of the listed services. You can change the secret by generating a new value and restarting pods to pick up the new value. In a two data center deployment, you must manually copy the new secret to the other site.

Procedure

Generate a new secret and apply it to the deployment using the appropriate steps for your environment:

- Single data center
  Run the following command to generate a new secret and apply it to the deployment:

  ```
  kubectl -n <namespace> patch secret portal-enc-key -p "{\"data\": {\"encryption_secret\":\"$(head -c74 /dev/urandom | base64 -w0 | tr '+/=' 'abc' | base64 -w0)\"}}"
  ```

  where ***namespace*** is the namespace where you installed the portal subsystem.

  The **portal-enc-key** was generated during installation and added to the CR as the **encryptionSecret** setting. When you generate a new secret, the value is updated automatically. If you saved the secret in a file after the Portal installation as recommended, be sure to update that file now.

- Two data centers
  a. Generate the new secret on DC1 by running the following command:

  ```
  head -c74 /dev/urandom | base64 -w0 | tr '+/=' 'abc' | base64 -w0 > secret.txt
  ```

  The **portal-enc-key** was generated during installation and added to the CR as the **encryptionSecret** setting. When you generate a new secret, the value is updated automatically. If you saved the secret in a file after the Portal installation as recommended, be sure to update that file now.

  b. Open a terminal to each DC in the same working directory where you saved **secret.txt** (or, copy the file to somewhere you can open a terminal to each DC).
  c. In each terminal, verity that you can access **secret.txt** by typing the following command:

  ```
  echo $(<secret.txt)
  ```

  d. In each terminal, type the following command -- but do not press Enter yet:

  ```
  kubectl -n <namespace> patch secret portal-enc-key -p "{\"data\": {\"encryption_secret\":\"$(<secret.txt)\"}}"
  ```

  where ***namespace*** is the namespace where you installed the portal subsystem.

  e. Press Enter in both terminals at the same time (or as close in time as possible).
  There is a 5-minute time-out that starts as soon as any of the pods has the new secret mounted by Kubernetes. All pods will get the secret at slightly different times, but within about a minute of each other. If the 5-minute time-out expires before all pods across both DCs have the new secret, then the pods will rotate the new secret in at different times, resulting in errors in the logs and some down time for various pods, until they manage to rotate the new secret into use and recover.

Results

When pods restart, the new secret is used to secure the services. The **portal-www** admin logs display messages as the new secret is used to re-encrypt the database. The following example shows sample log messages when the updated secret is applied to the database:

```
[   upgrade stdout]  2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: NEW k8s encryption key detected on this system!
Reencrypting portal data
[   upgrade stderr]  2954 888ec0:73add2:7fce1b 2020-08-06 13:16:21: refresh_encryption_key: Command Started:
/opt/ibm/bin/refresh_encryption_key
FEgX8F5MXtwvoJ8Wpxw5DB/6MKK/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zhl1rVNFZTlzRnVfkGheLr9Le/Pb9jq
[   upgrade stdout]  2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: No portal service exists! Simply overriding the key
[   upgrade stdout]  2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: New key installed
(FEgX8F5MXtwvoJ8Wpxw5DB/6MKK/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zhl1rVNFZTlzRnVfkGheLr9Le/Pb9jq)
[   upgrade stderr]  2954 888ec0:73add2:7fce1b 2020-08-06 13:16:21: refresh_encryption_key: Command Finished:
/opt/ibm/bin/refresh_encryption_key
FEgX8F5MXtwvoJ8Wpxw5DB/6MKK/qPKfRt5FaId3jy5IjbpXL8wi3/33q3KOySh8/zhl1rVNFZTlzRnVfkGheLr9Le/Pb9jq with RC 0
[   upgrade stderr]  2872 888ec0:8cb2cc:73add2 2020-08-06 13:16:21: Command Finished: /opt/ibm/bin/sysupgrade with RC 0
```

If there is a portal service registered and developer portal sites installed, then this task re-encrypts that data as well. When the site encryption is complete, the log displays a "Command Finished" message for the **refresh_encryption_key** command, as shown in the following example:

```
Command Finished: /opt/ibm/bin/refresh_encryption_key <KEY> with RC 0
```

Changing the portal `client_secret`

Change the **client_secret** for the portal subsystem to keep it in sync with the management subsystem.

About this task

The portal subsystem uses the same **client_secret** as the management subsystem. If you change the **client_secret** on the management subsystem, update the portal subsystem by pulling the credential from the management subsystem.

Note: If you did not deploy the portal subsystem, skip this task.

Procedure

1. On a portal pod, run the following command to pull the portal service's **client_secret** from the management subsystem:

   ```
   kubectl -n namespace exec -t portal-mydc-www-0 -- bash -ic refresh_cloud_credentials
   ```

   where ***namespace*** is the namespace where you installed the portal subsystem.

2. Then, run the following command to update the credential for the portal sites:
   Note: If you did not deploy any portal sites, skip this step.

   ```
   kubectl -n namespace exec -t portal-mydc-www-0 -- bash -ic "refresh_site_credentials -a"
   ```

   where ***namespace*** is the namespace where you installed the portal subsystem.

Backing up, restoring, and disaster recovery

Backup your API Connect subsystems, configure scheduled database backups, and recover from a disaster.

Backups for the management, portal, and analytics subsystems consist of an infrastructure configuration backup and a database backup.
Note: The gateway receives all its configuration from the management subsystem, and does not require a backup.
Note: If you installed API Connect with Cloud Pak for Integration, you can use Red Hat OpenShift API for Data Protection (OADP) to backup your infrastructure configuration and subsystem databases. For more information about OADP, see Administering backup and restore in Cloud Pak for Integration.

Infrastructure configuration backup
: Your infrastructure configuration backup includes everything that you configure for API Connect in your deployment environment, such as:

  - Subsystem YAML files (or top-level CR YAML file).
  - Custom certificates. Such as certificates used to secure communication with remote systems like analytics offload targets.
  - Encryption secrets.
  - Backup secrets.

  The infrastructure configuration backup is also referred to as the "config backup".

  If you have a disaster, your config backup is essential for restoring your API Connect subsystems.

  Config backups must be taken manually, by exporting your API Connect Kubernetes artifacts to YAML files. If you make a configuration change, you must update your config backup.

Subsystem database backups
: Your subsystem database backups contain everything that API Connect users configure in the API Connect UIs, the toolkit CLI, and the REST API. Subsystem database backups for portal contain all site customizations. The analytics database backup contains all your analytics data.

  Subsystem database backups can be configured to run automatically, and can also be taken on-demand.

  Important points:

  - Subsystem database backups are for recovery in the same environment that the backups were taken, or in a different environment that has the same network configuration and form factor. If you want to move your API Connect deployment to a different environment and change the form factor, or modify your API Connect endpoints, then see Migrating from v10 to v10 on a different form factor.
  - The management and portal subsystems databases must be kept in sync with each other, so take management and portal database backups at the same time. When you perform a management or portal database restore, complete the restoration of the management database first, and then restore the developer portal.

Two data center disaster recovery deployments

Two data center disaster recovery deployments have additional backup, restore, and disaster recovery considerations. Review the Backup and restore requirements for a 2DCDR deployment before you follow the topics in this section.

- **Backing up and restoring the management subsystem**
  How to backup and restore the infrastructure configuration and database of your management subsystem.
- **Backing up and restoring the developer portal**
  How to backup and restore the infrastructure configuration and database of your portal subsystem.

- **Backing up and restoring the analytics subsystem**
  How to configure analytics backups and recover from a disaster.
- **Backing up and restoring on OpenShift top-level CR**
  How to backup and restore your top-level CR deployment of API Connect
- **Backing up and restoring on Cloud Pak for Integration and OpenShift top-level CR**
  How to backup and restore all API Connect subsystem in a Cloud Pak for Integration, or OpenShift top-level CR deployment

Backing up and restoring the management subsystem

How to backup and restore the infrastructure configuration and database of your management subsystem.

The following topics cover how to backup, restore, and recover your management subsystem from a disaster.

- **Taking a management infrastructure configuration backup**
  How to backup your management subsystem deployment configuration.
- **Configuring management database backups**
  Configure scheduled database backups of your management subsystem.
- **Running an on-demand backup of the management database**
  Deploy the `Backup` CR to initiate a backup of the management database.
- **Restoring from a management database backup**
  Restore a management database backup, either with a `ManagementRestore` custom resource (CR), or by using a backup ID.
- **Recovering from a disaster**
  Reinstall the management subsystem by using your infrastructure configuration backup, then restore the management database backup.
- **Troubleshooting management database backup and restore**
  Common problems and how to diagnose issues with backup and restore.

Taking a management infrastructure configuration backup

How to backup your management subsystem deployment configuration.

About this task

Your infrastructure configuration backup includes everything that you configure for API Connect in your deployment environment, such as:

- Subsystem YAML files (and top-level CR YAML file if used).
- Custom certificates.
- Encryption secrets.
- Backup secrets.

The infrastructure configuration backup is also referred to as the "config backup".

If you have a disaster, your config backup is essential for restoring your API Connect subsystems.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Export the management CR to a file called mgmt_cr_backup.yaml:

   ```
   kubectl -n <management namespace> get ManagementCluster -o yaml > mgmt_cr_backup.yaml
   ```

2. Export the management database encryption secret to a file called management_enc_key_backup.yaml:
   a. Get the name of the encryption secret:

      ```
      kubectl -n <management namespace> get mgmt -o yaml | grep encryption
      ```

   b. Take note of the `encryptionSecret` name returned:

      ```
      encryptionSecret: <management enc key>
      ```

   c. Backup the encryption secret to a YAML file:

      ```
      kubectl -n <management namespace> get secret <management enc key> -o yaml > management_enc_key_backup.yaml
      ```

3. Export your management database backup secret:

   ```
   kubectl -n <management namespace> get secret <mgmt backup secret> -o yaml > mgmt-backup-secret_backup.yaml
   ```

   The backup secret is created when you configure database backups: Create backup secret. If database backups are not yet configured, ensure that this secret is backed up when it is configured.

4. If you created a secret for your S3 store's CA certificate, take a backup of this secret:

   ```
   kubectl -n <management namespace> get secret <mgmt custom server ca> -o yaml > mgmt-custom-server-ca_backup.yaml
   ```

   The S3 CA secret is created when you configure database backups: Create S3 CA secret. If database backups are not yet configured, ensure that this secret is backed up when it is configured.
5. Export the management client application credential secrets to YAML files:
   a. Get the names of the credential secrets:

```
kubectl -n <management namespace> get mgmt -o yaml | grep CredentialSecret
```

Expected output is:

```
atmCredentialSecret: management-atm-cred
consumerToolkitCredentialSecret: management-ccli-cred
consumerUICredentialSecret: management-cui-cred
designerCredentialSecret: management-dsgr-cred
discoveryCredentialSecret: management-discovery-cred
governanceCredentialSecret: management-governance-cred
juhuCredentialSecret: management-juhu-cred
toolkitCredentialSecret: management-cli-cred
uiCredentialSecret: management-ui-cred
```

b. Backup each credential secret to a YAML file:

```
kubectl -n <management namespace> get secret <secret name> -o yaml > <secret name>_backup.yaml
```

For example, to backup the ATM credential secret:

```
kubectl -n <management namespace> get secret management-atm-cred -o yaml > management-atm-cred_backup.yaml
```

c. Edit each credential secret YAML file and remove both the **ownerReferences** subsection and the **selfLink** property.
Example of the **ownerReferences** and **selfLink** properties to be removed:

```
ownerReferences:
  - apiVersion: management.apiconnect.ibm.com/v1beta1
    blockOwnerDeletion: true
    controller: true
    kind: ManagementCluster
    name: management
    uid: 623e6b20-7eb8-46ce-94ac-6b64cd71afc4
  selfLink: /api/v1/namespaces/default/secrets/management-atm-cred
```

6. Export any other certificates that you customized. For example, if you customized the **apiManagerEndpoint** certificate, save the certificate by copying the corresponding secret to a YAML file:

```
kubectl -n <management namespace> get secret apim-endpoint -o yaml > apim-endpoint_secret_backup.yaml
```

Configuring management database backups

Configure scheduled database backups of your management subsystem.

Before you begin

You must have a remote SFTP server or S3-compatible object-store for storing your management database backups. Example S3-compatible object-stores:

- AWS S3.
- IBM Cloud Object Storage.
- Custom S3 storage.

The object-store's backup folder must be empty.

About this task

Important points:

- Management database backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a management database backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see: Migrating from v10 to v10 on a different form factor.
- Ensure that you regularly take a Taking a management infrastructure configuration backup. If a disaster occurs and you lose your management subsystem configuration, then you cannot restore your management database backup without first restoring the config backup.
- Take portal database backups at the same time as you take management database backups.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Procedure

1. Create a backup secret.
The backup secret is a Kubernetes secret that contains your access key and secret for your SFTP server or object-store.
Create the backup secret with the following command:
   - Object-store:

     ```
     kubectl -n <management namespace> create secret generic mgmt-backup-secret --from-literal=key='<access key>' \
     --from-literal=keysecret='<access secret>'
     ```

     where *<access key>* and *<access secret>* are the access credentials for your object-store.
   - SFTP username and password:

     ```
     kubectl -n <management namespace> create secret generic mgmt-backup-secret --from-literal=username='<username>' --
     from-literal=password='<password>'
     ```

   - SFTP username and SSH key:

```
kubectl -n <management namespace> create secret generic mgmt-backup-secret --from-literal=username='<username>' --
from-file=ssh-privatekey='<privatekeyfile>' [--from-literal=password='<privatekey_passphrase>']
```

Take a backup of this secret and keep it with your Taking a management infrastructure configuration backup.

Important: It is recommended to regularly update your backup secret:

a. Run the same `kubectl create secret generic <secret name>` command, but with a new secret name and your updated access key and secret.
b. Edit your management CR to update the secret name in `spec.databaseBackup.credentials`.
c. Reload the secret in the management subsystem with:

```
 kubectl annotate mgmt <mgmt-subsystem-name> apiconnect-operator/management-db-reloaded-at=$(date -u +"%Y-%m-
%dT%H:%M:%SZ") -n <management namespace> --overwrite
```

where *<mgmt-subsystem-name>* is the name of your management subsystem CR.

2. If your object-store has a custom CA certificate, then create a Kubernetes secret that contains this CA certificate, so that your management subsystem trusts the object-store.

a. Run the following command to create a Kubernetes secret from the certificate file:

```
kubectl -n <management namespace> create secret generic mgmt-custom-objstore-ca --from-file=ca.crt=/path/to/cert.crt
```

Note: Include the complete chain in your certificate file, for example:

```
intermediate-certificate-1
intermediate-certificate-2
. . .
intermediate-certificate-n
root-certificate
```

The first certificate (intermediate-certificate-1) is the issuer of the object-store server certificate, and each subsequent certificate is the issuer of the preceding certificate. The root certificate must be self-signed.
If the certificate includes no intermediate certificates, then the file contains only the root certificate.

b. Take a backup of the new secret.

```
kubectl -n <management namespace> get secret mgmt-custom-objstore-ca -o yaml > mgmt-custom-objstore-ca.yaml
```

Keep the generated mgmt-custom-objstore-ca.yaml file with your management infrastructure backup.

3. **Kubernetes and OpenShift individual subsystem CR users:** Edit your `ManagementCluster` CR:

```
kubectl -n <management namespace> edit ManagementCluster
```

4. **Cloud Pak for Integration and OpenShift top-level CR users:** Edit your `APIConnectCluster` CR:

```
oc -n <apic namespace> edit APIConnectCluster
```

5. Configure your backup settings in the `databaseBackup` section of the `spec` object:

```
spec:
  databaseBackup:
    host: <host>/<region>
    port: <port number>
    protocol: [local|sftp|objstore]
    path: <path>
    credentials: <backup secret>
    backupCerts: <custom CA certificate>
    schedule: "<cron schedule>"
    repoRetentionFull: <number of days>
    backups3URIStyle: <path/host> # host or virtual style is the default
```

Note: On Cloud Pak for Integration and OpenShift when using the top-level CR, add the `databaseBackup` section to the `spec.management` section.
Set the properties as follows:

- `host` hostname of your remote SFTP server or object-store endpoint. If you are using an object-store and your endpoint does not have a region, then omit */<region>*.
- `port` is the listening port on your remote SFTP server or object-store. Defaults are 22 for SFTP and 443 for object-store.
- `path` is the location for your backups on your remote SFTP server or object-store. If you are using an object-store the format must be: `bucket_name/folder`.
- `protocol`: Type of remote backup site, `objstore` or `sftp`. If you do not have a remote backup site then, set to `local`.
- `credentials` is the name of the backup secret that you created in step 1.
- `backupCerts` is the CA certificate secret that is created in step 2.
- `schedule` is the schedule for when database backups are run, in `cron` format:

```
    * * * * *
    - - - - -
    | | | | |
    | | | | +----- day of week (0 - 6) (Sunday=0)
    | | | +------- month (1 - 12)
    | | +--------- day of month (1 - 31)
    | +----------- hour (0 - 23)
    +------------- min (0 - 59)
    +------------- sec (0 - 59)
```

For example:

```
0 0 1 * * *
```

runs a backup at 1 AM every day.

The default is an empty string (no backup configured).

Note: Set the same schedule as your developer portal database backups.

- **repoRetentionFull** is the number of days to retain backups for. For example, if **repoRetentionFull** is set to 30, then any backups older than 30 days are deleted.

  ```
  Minimum: 1
  Maximum: 9999999
  Default: 0 (No retention)
  ```

  Important points:
  - The **repoRetentionFull** start day is reset to the current day when you restore a management database backup.
  - **repoRetentionFull** applies to both manual backups and scheduled backups.
  - When older backups are deleted, their corresponding **backup** CR is deleted.
- **backups3URIStyle** applies to backups to object-store only. Indicates whether URIs to your object-store backup specify a host or a path value. Set to either **host** or **path**. The default is **host**.
  Some custom object-store providers require URI style to be set to **path**. For example, MinIO supports both host and path style setup. You can create a MinIO S3 server to accept only path style client communications.

  Important: Contact your custom object-store administrator before you configure this field. If not properly configured, an upstream custom object-store can reject connections from the client, such as the management subsystem.

6. Update the **ManagementCluster** CR.
   If you are using Cloud Pak for Integration or OpenShift with the top-level CR, also update your **APIConnectCluster** CR.

What to do next

Run an on-demand backup to confirm that your backup configuration is correct, see Running an on-demand backup of the management database.

Running an on-demand backup of the management database

Deploy the **Backup** CR to initiate a backup of the management database.

About this task

If you are taking a management database backup, you should also take a portal database backup for all registered portal services. Management and portal databases must be kept in sync.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Procedure

1. Verify the health of your **ManagementCluster**:

   ```
   kubectl -n <management namespace> get ManagementCluster
   ```

   The status should show **Running**, and all pods should be up:

   ```
   NAME   READY   STATUS    VERSION      RECONCILED VERSION   AGE
   mgmt   n/n     Running   10.0.8.0     10.0.8.0             19h
   ```

   Note: On Cloud Pak for Integration a **keycloak** cluster is also shown in this output. Check the status on the **ManagementCluster** only.
2. Identify the management database cluster name:

   ```
   kubectl -n <management namespace> get cluster
   ```

   Example output that shows the database cluster name is **m1-dc1-db**:

   ```
   NAME         AGE   INSTANCES   READY   STATUS                     PRIMARY
   m1-dc1-db    8d    3           3       Cluster in healthy state   m1-dc1-db-1
   ```

3. Create a file called mgmtbackup_cr.yaml and paste in the following text:

   ```
   apiVersion: postgresql.k8s.enterprisedb.io/v1
   kind: Backup
   metadata:
     generateName: mgmt-backup- # prefix for the name of the backup CR that is generated.
   spec:
     cluster:
       name: <database cluster name>
   ```

   where *<database cluster name>* is the cluster name that you identified in step 2.

4. Create the **Backup** CR from the mgmtbackup_cr.yaml file:

   ```
   kubectl -n <management namespace> create -f mgmtbackup_cr.yaml
   ```

5. Verify that the backup is running with:

   ```
   kubectl -n <management namespace> get backup -o custom-
   columns="name:.metadata.name,backupId:.status.backupId,endpoint:.status.endpointURL,path:.status.destinationPath,servernam
   e:.status.serverName,status:.status.phase"
   ```

   The expected output when the backup is completed is:

   ```
   name                 backupId          endpoint                                    path                        servername
   status
   ```

```
test-backup-1.17.1   20230831T110022   https://apic-mgmt-s3proxy.default.svc:8765   s3://backups/backup01ibm   apic-mgmt-
d54a2194-db-2023-08-31T11:49:10+01:00   completed
```

Do not delete the **Backup** CR when the backup is complete. The **Backup** CR is required to restore the backup.

What to do next

Take a database backup of any portal subsystems that are registered with this management subsystem: Running an on-demand backup of the portal database.

Restoring from a management database backup

Restore a management database backup, either with a **ManagementRestore** custom resource (CR), or by using a backup ID.

Use a **ManagementRestore** CR when your management subsystem still has the **Backup** CR that was used to take the backup you want to restore.

Restore with a backup ID when your management subsystem does not have the **Backup** CR corresponding to the backup you want to restore. This situation can occur if the **Backup** CR was deleted, or in a disaster recovery situation where reinstall of the management subsystem is required.

- **Restoring the management database with a backup CR**
  Create a **ManagementRestore** CR that references the **Backup** CR of the backup you want to restore.
- **Restoring the management database with a backup ID**
  If the **Backup** CR is missing, but the backup is present on your remote SFTP server or object-store, you can restore the backup by using the backup ID.

Restoring the management database with a backup CR

Create a **ManagementRestore** CR that references the **Backup** CR of the backup you want to restore.

About this task

- Management database backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a management database backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see Migrating from v10 to v10 on a different form factor.
- When you restore a management database backup, you must also restore the database backups of all registered developer portal services, so that the portal and management databases remain in sync.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Procedure

1. Identify the existing backup CR that you want to restore:

   ```
   kubectl -n <management namespace> get backup -o custom-
   columns="name:.metadata.name,backupId:.status.backupId,endpoint:.status.endpointURL,path:.status.destinationPath,servernam
   e:.status.serverName,status:.status.phase"
   ```

   Example output:

   ```
   NAME                  BACKUPID          ENDPOINT                          PATH                         SERVERNAME
   STATUS
   test-backup-1.17.1   20230831T110022   https://seaweed.default.svc:30333   s3://backups/backup01ibm   apic-mgmt-d54a2194-
   db-2023-08-31T11:49:10+01:00   completed
   ```

   The backup name in this example is **test-backup-1.17.1**. You can restore the management database from any backup where the **STATUS** is **completed**.

   If you cannot find the backup CR you want, but it is present on your remote SFTP server or object-store, then you can restore with the backup ID: Restoring the management database with a backup ID.

2. Verify that the backup is present in your remote SFTP server or object-store:
   For example, on an AWS S3 store, run:

   ```
   aws s3 ls <path>
   ```

   where *<path>* is the location on your object-store store you configured for your management database backups.
3. Create a file called mgmtrestore_cr.yaml, and paste in the following text:

   ```
   apiVersion: management.apiconnect.ibm.com/v1beta1
   kind: ManagementRestore
   metadata:
     generateName: management- # this the prefix for the name of the restore CR that is created
   spec:
     backupName: <backup CR name>
     subsystemName: <management CR name>
   ```

   where
   - *<backup CR name>* is the backup name that you identified in step 1.
   - *<management CR name>* is the name of your **ManagementCluster** CR, run **kubectl get mgmt** to see what this name is.

   Note: If the management database encryption key was changed since the backup was taken (because you followed the steps in Changing the database encryption key), then you must restore the original encryption key before you apply the restore CR. See restore old encryption key.

4. Start the restore by creating the **ManagementRestore** CR from the YAML file:

```
kubectl -n <management namespace> create -f mgmtrestore_cr.yaml
```

5. Verify that the restore is running with:

```
kubectl -n <management namespace> get ManagementRestore --sort-by=.metadata.creationTimestamp
```

Example output:

```
NAME                  STATUS      BACKUP               CLUSTER       MESSAGE                                          PITR
AGE
mgmt-restore-hr9zx    Complete    mgmt-backup-xnjkl    m1            Restore process completed (DB Restore + DRR job)    9m8s
```

What to do next

Restore the database backups of any developer portal services that are registered with the management subsystem: Restoring from a portal database backup.

Restoring the management database with a backup ID

If the **Backup** CR is missing, but the backup is present on your remote SFTP server or object-store, you can restore the backup by using the backup ID.

About this task

Restore of the management database with a backup ID is required in a disaster recovery scenario, where you redeployed your management subsystem and restored your infrastructure configuration from your config backup.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Procedure

1. Identify the backup ID and path of the backup that you want to restore from your remote SFTP server or object-store.
   Management database backups appear as folders that use a datestamp for their name, and are located inside the backup path. Example of a management database backup with its full path:

```
apic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z/base/20230914T013040
```

   - **apic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z** is the backup path. The datestamp **2023-09-14T01:30:40Z** indicates when the management database was created (not when the backup was created). The management database is created on initial installation, and re-created when a backup restore is run. The path with the most recent datestamp should contain the most recent backups.
   - **20230914T013040** is the backup ID. The format indicates the date and time that the backup was taken.
2. Create a file called mgmt-restore.yaml and paste in the following text:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementRestore
metadata:
  generateName: management- # this the prefix for the name of the restore CR that is created
spec:
  subsystemName: <management CR name>
  backup:
    protocol: [sftp|objstore]
    host: <host>/<region>
    port: <port number>
    path: <path>
    credentials: <backup secret>
    backupCerts: <custom CA certificate>
    backups3URIStyle: <path/host> # host or virtual style is the default
  backupId: <backup ID>
```

   where:
   - **subsystemName** is the name of your **ManagementCluster** CR, run **kubectl get mgmt** to see what this name is.
   - **protocol** is the remote backup server type. Set to **sftp** or **objstore**.
   - **host** is the remote SFTP server hostname or object-store endpoint. If you are using an object-store and your endpoint does not have a region, then omit */<region>*.
   - **port** is the listening port on your remote SFTP server or object-store. Defaults are 22 for SFTP and 443 for object-store.
   - **path** is the path that you identified in step 1.
   - **credentials** is the backup secret that you configured to authenticate with the remote backup site. See Create backup secret.
   - **backupCerts** is the CA certificate secret of the remote SFTP server or object-store. See step 2 on Configuring management database backups. If you did not create this secret during backup configuration, then omit this property.
   - **backups3URIStyle** applies to backups to object-store only. Indicates whether URIs to your object-store backup specify a host or a path value. Set to either **host** or **path**. The default is **host**.
   - **backupId** is the ID that you identified in step 1.

   Example mgmt-restore.yaml file that uses the values from step 1:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementRestore
metadata:
  generateName: management-
spec:
  subsystemName: management
  backup:
    protocol: objstore
    host: s3.ibm.com/us-west
```

```
    path: pic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z
    credentials: mgmt-backup-secret
  backupId: 20230914T013040
```

Note: If the management database encryption key was changed since the backup was taken (because you followed the steps in Changing the database encryption key), then you must restore the original encryption key before you apply the restore CR. See restore old encryption key.

3. Start the restore by creating the **ManagementRestore** CR from the mgmt-restore.yaml file:

```
kubectl -n <management namespace> create -f mgmt-restore.yaml
```

4. Verify that the restore is running with:

```
kubectl -n <management namespace> get ManagementRestore --sort-by=.metadata.creationTimestamp
```

Example output:

```
NAME                  STATUS      BACKUP               CLUSTER       MESSAGE                                                 PITR
AGE
mgmt-restore-hr9zx    Complete    mgmt-backup-xnjkl    m1            Restore process completed (DB Restore + DRR job)    9m8s
```

What to do next

Restore the database backups of any developer portal services that are registered with the management subsystem: Restoring from a portal database backup.

Recovering from a disaster

Reinstall the management subsystem by using your infrastructure configuration backup, then restore the management database backup.

Before you begin

To successfully recover the management subsystem, you must have the following backups:

- Management infrastructure configuration backup.
- Management database backup

About this task

- Management subsystem backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a management subsystem backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see Migrating from v10 to v10 on a different form factor.
- When you restore a management database backup, you must also restore the database backups of all registered developer portal services, so that the portal and management databases remain in sync.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Procedure

1. Reinstall your management subsystem by using the YAML files from your infrastructure configuration backup.
   Your infrastructure configuration backup consists of:
   - Management CR YAML: mgmt_cr_backup.yaml.
   - Management database encryption secret: management_enc_key_backup.yaml.
   - Management backup secret: mgmt-backup-secret_backup.yaml
   - Multiple <credential secret>_backup.yaml files, one for each credential secret.
   - If you customized any certificates, a YAML file of the secret for each customized certificate. For example: apim-endpoint_secret_backup.yaml.

   a. Create the database encryption secret with the management_enc_key_backup.yaml file:

   ```
   kubectl -n <management namespace> apply -f management_enc_key_backup.yaml
   ```

   b. Create the backup credential secret with your mgmt-backup-secret_backup.yaml file:

   ```
   kubectl -n <management namespace> apply -f mgmt-backup-secret_backup.yaml
   ```

   c. Create the credential secrets with the <credential secret>_backup.yaml files you saved in step 5 of Taking a management infrastructure configuration backup:

   ```
   kubectl -n <management namespace> apply -f <credential secret backup file>
   ```

   d. Set the object-store CA secret (if required) from your backup file:

   ```
   kubectl -n <management namespace> apply -f mgmt_custom_objstore_ca.yaml
   ```

   e. Create the secrets for any customized certificates from their backup files:

   ```
   kubectl -n <management namespace> apply -f <custom certificate secret backup file>
   ```

   f. Install the management subsystem. Follow Installing the management subsystem, but use the settings from the **spec** section of your mgmt_cr_backup.yaml file.

2. Restore your management database: Restoring the management database with a backup ID.

What to do next

Restore the backups of any portal subsystems that are registered with the management subsystem. See Backing up and restoring the developer portal.

Troubleshooting management database backup and restore

Common problems and how to diagnose issues with backup and restore.

Common problems with backup and restore

These are some frequent issues that can cause backup or restore to fail:

- Invalid login credentials for your remote backup server. Check that the username and password that you configured in your subsystem database backup settings is correct.
- The user does not have write permissions on the backup server. Check that the username you configured in your subsystem database backup settings has write permission to the specified backup path.
- Remote backup server storage full. Check your remote backup server and if the storage is full either extend the storage space or delete older backups.
- No network access to the remote backup server. Check that you can communicate with your remote backup server from your API Connect environment.
- TLS handshaking failure with the remote backup server. If your remote backup server has a self-signed CA certificate, check that this certificate is trusted by your API Connect deployment, see the database backup configuration steps for your subsystem for more information.

Backup or restore CR stuck in running or in a failed state.

Describe the backup or restore CR for more information on the problem:

```
kubectl -n <namespace> describe backup backup-1700143802
```

```
Name:          management-1700143800
Namespace:     apic
Labels:        k8s.enterprisedb.io/cluster=management-dc1-db
               k8s.enterprisedb.io/immediateBackup=false

```

Unable to find database backup CRs

If **kubectl get backup** does not return the backup that you want to restore, then search for the backup on your SFTP server or object-store.

The path to API Connect management database backups on the remote SFTP server or object-store has the following format:

<backup path>/<mgmt db cluster name>-<time when db was created>/base/<backup ID>

- *<backup path>* is the path that is defined in your management CR: backup settings. The format is **bucket_name/folder**.

If your API Connect deployment was upgraded from v10.0.6.0 or earlier, then **/edb** is appended to the path.

- *<mgmt db cluster name>* is the name of your management database cluster. Identify this name with:

  ```
  kubectl -n <management namespace> get cluster -n active
  ```

  See get cluster name.
- *<time when db was created>* is a timestamp of when the management subsystem database was created. The format is: **2023-12-25T00:00:00Z**. Whenever you do a management database restore, a new management database is created, and so a new directory is created where subsequent database backups are stored.
- *<backup ID>* is the ID of a management database backup. The format is **YYYYMMDDTHHMMSS**. This is a directory that contains all the files that comprise the database backup.

Example path:

```
s3bucket1/folder2/mgmt-db-2023-12-25T00:00:00Z/base/20231225T094400
```

With the information identified, you can restore the backup by using the Restoring the management database with a backup ID method.

Error when restoring a management subsystem with the API discovery service

If you enable the API discovery service, the backups that you take can be restored only onto a management subsystem that also has the API discovery service enabled. If you try to restore a backup onto a management subsystem that doesn't have the API discovery service enabled, the database recovery jobs will go into an error state, and the logs will contain the following tablespaces directory error:

```
[Errno 30] Read-only file system: '/var/lib/postgresql/tablespaces'
```

The status of the management job pods will look like the following output:

```
management-apim-restore-1bc41b74-sjzzp                            0/1     Completed   0               3h28m
management-bf631b70-db-1-full-recovery-41bdv                      0/1     Error       0               11m
management-bf631b70-db-1-full-recovery-72519                      0/1     Error       0               13m
management-bf631b70-db-1-full-recovery-8mhdk                      0/1     Error       0               103s
```

In this case, you must take the following steps.

1. Update the **ManagementCluster** CR to enable the API discovery service:

   ```
   spec:
     ...
     discovery:
       enabled: true
       proxyCollectorEnabled: true
   ```

2. Apply the updated CR by running the following command:

   ```
   kubectl apply -f management_cr.yaml -n <management_namespace>
   ```

   Where *management_namespace* is the name of the target installation namespace in the Kubernetes cluster.
3. Find the name of the EDB PostgreSQL cluster, by running the following command:

   ```
   kubectl get cluster -n <namespace>
   ```

   The output will look similar to the following output:

   ```
   NAME                      AGE   INSTANCES   READY   STATUS                 PRIMARY
   management-bf631b70-db    13m   1                   Setting up primary
   ```

4. Wait until the EDB PostgreSQL cluster has been updated with the **tablespaces** configuration. You can check this status by running the following command:

   ```
   kubectl get cluster <cluster-name> -o yaml -n <namespace>
   ```

   Look in the output for the **tablespaces** entry, which looks like the following example:

   ```
      tablespaces:
      - name: apidiscoverysvc
        owner:
          name: apicuser
        storage:
          resizeInUseVolumes: false
          size: 10Gi
          storageClass: local-storage
        temporary: false
   ```

   Note that the cluster status will still be **Setting up primary** at this point.
5. Delete the EDB PostgresSQL cluster by running the following command:

   ```
   kubectl delete cluster <cluster-name> -n <namespace>
   ```

6. After a few moments the EDB PostgreSQL cluster will be recreated by the IBM® API Connect operator. You can check this by running the following command:

   ```
   kubectl get cluster -n <namespace>
   ```

7. The database recovery jobs will eventually be recreated, and succeed. You can then verify that the PVCs for the **tablespaces** have been recreated by running the following command:

   ```
   kubectl get pvc -n <namespace>
   ```

   The output of this command will show that there are one or more PVCs present, with a name similar to **management-bf631b70-db-1-tbs-apidiscoverysvc**.
8. The API discovery service pods will now start, and the restore operation will complete.

For more information about the API discovery service, see Enabling API discovery on Kubernetes.

Backing up and restoring the developer portal

How to backup and restore the infrastructure configuration and database of your portal subsystem.

- **Taking a portal infrastructure configuration backup**
  Create YAML backup files of your portal subsystem's Kubernetes configuration.
- **Configuring portal database backups**
  Configure scheduled database backups of your portal subsystem.
- **Running an on-demand backup of the portal database**
  Deploy the `PortalBackup` CR to initiate a backup of the portal database.
- **Managing your remote portal database backups**
  How to manage your remote portal database backup resources.
- **Restoring from a portal database backup**
  Create a `PortalRestore` CR to restore your management database.
- **Recovering from a disaster**
  Reinstall the portal subsystem by using your infrastructure configuration backup, then restore the portal database backup.
- **Troubleshooting portal database backup and restore**
  Troubleshoot problems with portal database backups and restores.

Taking a portal infrastructure configuration backup

Create YAML backup files of your portal subsystem's Kubernetes configuration.

About this task

A portal infrastructure configuration backup is essential for disaster recovery. Take an infrastructure configuration backup after installation, and whenever you make an update to your portal's Kubernetes configuration.

If you have multiple portal clusters in the same namespace, include the portal CR name in all `kubectl get PortalCluster` commands provided in this topic. For example:

```
kubectl -n <portal namespace> get PortalCluster <portal CR name>
```

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Procedure

1. Export the portal CR to a file called portal_cr_backup.yaml:

   ```
   kubectl -n <portal namespace> get PortalCluster -o yaml > portal_cr_backup.yaml
   ```

2. Export the portal database encryption secret to a file called portal_enc_key_backup.yaml:
   a. Get the name of the encryption secret:

      ```
      kubectl -n <portal namespace> get ptl -o yaml | grep encryption
      ```

   b. Take note of the `encryptionSecret` name returned:

      ```
      encryptionSecret: <portal enc key>
      ```

   c. Backup the encryption secret to a YAML file:

      ```
      kubectl -n <portal namespace> get secret <portal enc key> -o yaml > portal_enc_key_backup.yaml
      ```

3. Export your portal database backup secret:

   ```
   kubectl -n <portal namespace> get secret <portal backup secret> -o yaml > ptl-backup-secret_backup.yaml
   ```

   The backup secret is created when you configure portal database backups. If database backups are not yet configured, remember to backup this secret when they are configured.
4. If used, export your remote portal backup server's CA secret:

   ```
   kubectl -n <portal namespace> get secret <portal custom server ca> -o yaml > portal-custom-server-ca_backup.yaml
   ```

   The S3 CA secret is created when you configure database backups: Create backup server CA secret. If database backups are not yet configured, remember to backup this secret when they are configured.
5. Export any other certificates that you customized. For example, if you customized the `portalWeb` endpoint certificate, save the certificate by copying the corresponding secret to a YAML file:

   ```
   kubectl -n <portal namespace> get secret <portalWeb secret> -o yaml > portalWeb_secret_backup.yaml
   ```

What to do next

Configure scheduled database portal backups: Configuring portal database backups.
Important: If you update your portal subsystem's Kubernetes configuration, remember to update your infrastructure configuration backup.

Configuring portal database backups

Configure scheduled database backups of your portal subsystem.

About this task

The developer portal by default takes database backups of itself every 24 hours and stores the last three days of backups in the portal subsystem PVCs (older backups are automatically deleted). These backups are called local backups because they are stored locally rather than on remote backup servers. For disaster recovery, you must configure the portal to create and store backups on a remote server.

Supported remote servers for backup storage are:

- S3 object-store, for example:
  - AWS S3.
  - IBM Cloud Object Storage.
  - Custom S3 storage.

  Only password-based authentication is supported for S3, not authentication based on public certificates and private keys. Password-based authentication for S3 requires that you generate an access key and secret.
- SFTP
  Supported credentials types:
  - Username and password.
  - Username and SSH-key. Only OpenSSH keys are supported.[1]

Important points:

- Portal database backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a portal database backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see: Migrating from v10 to v10 on a different form factor.
- Keep your portal's Infrastructure configuration backup up to date with any changes in your portals Kubernetes configuration. If a disaster occurs and you lose your portal subsystem configuration, then you cannot restore your portal database backup without first restoring the config backup.
- Take management database backups at the same time as you take portal database backups. One backup per day is recommended.
- The portal keeps a log of the last 30 days of remote backups that are taken, configured with the **backupRecordDays** property. Configure the retention policy on your remote backup server to match or exceed the **backupRecordDays** value.
- To disable scheduled database backups, you must remove the entire **databaseBackup** section from the portal CR. Local backups continue to be taken in all cases.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Procedure

1. Create your backup secret:
   - For SFTP backup destination, use:
     - Username and password credentials:

       ```
       kubectl create secret generic portal-backup-secret --from-literal=username='<username>'
       --from-literal=password='<password>' -n <portal namespace>
       ```

     - Username and SSH-key credentials:

       ```
       kubectl create secret generic portal-backup-secret --from-literal=username='<username>'
        --from-file=ssh-privatekey='<private key filepath>' -n <portal namespace>
       ```

   - For S3 backup destination, use:

     ```
     kubectl create secret generic portal-backup-secret --from-literal=username='<S3 access key or username>'
         --from-literal=password='<S3 access key secret or password>' -n <portal namespace>
     ```

   Keep the backup secret in your Infrastructure configuration backup.
2. **S3 storage only:** If your S3 store has a custom CA certificate, then create a Kubernetes secret that contains this CA certificate, so that your portal subsystem trusts the S3 store.
   a. Run the following command to create a Kubernetes secret from the certificate file:

      ```
      kubectl -n <portal namespace> create secret generic portal-custom-server-ca --from-file=ca.crt=/path/to/cert.crt
      ```

      Note: Include the complete chain in your certificate file, for example:

      ```
      intermediate-certificate-1
      intermediate-certificate-2
      . . .
      intermediate-certificate-n
      root-certificate
      ```

      The first certificate (intermediate-certificate-1) is the issuer of the object-store server certificate, and each subsequent certificate is the issuer of the preceding certificate. The root certificate must be self-signed.
      If the certificate includes no intermediate certificates, then the file contains only the root certificate.

   b. Take a backup of the new secret.

      ```
      kubectl -n <portal namespace> get secret portal-custom-server-ca -o yaml > portal_custom_s3_ca.yaml
      ```

      Keep the generated portal_custom_s3_ca.yaml file with your Infrastructure configuration backup.

3. **Kubernetes and OpenShift individual subsystem CR users:** Edit your `PortalCluster` CR:

   ```
   kubectl -n <portal namespace> edit PortalCluster
   ```

4. **Cloud Pak for Integration and OpenShift top-level CR users:** Edit your `APIConnectCluster` CR:

   ```
   oc -n <apic namespace> edit APIConnectCluster
   ```

5. Configure your backup settings in the `portalBackup` section of the `spec` object:
   - For S3 object-store backup destination, use:

     ```
     spec:
       portalBackup:
         credentials: <portal backup secret>
         host: <host>/<region>
         path: <path>
         port: <port>
         protocol: objstore
         backupCerts: <custom CA certificate>
         backups3URIStyle: <path/host>
         schedule: '<cron schedule>'
         backupRecordDays: 30
     ```

   - For SFTP backup destination, use:

     ```
     spec:
       portalBackup:
         credentials: <portal backup secret>
         host: <sftp server hostname>
         path: <directory path>
         port: <port>
         protocol: sftp
         schedule: '<cron schedule>'
         backupRecordDays: 30
     ```

   Note: On Cloud Pak for Integration and OpenShift when using the top-level CR, add the `databaseBackup` section to the `spec.portal` section.
   Set the properties as follows:

Table 1. Developer Portal backup settings

Setting	Description
`credentials`	The name of the secret you created in step 1.
`host`	The hostname or your remote backup storage target: • S3 - `host`: is the S3 endpoint and region (if your S3 endpoint has a region) in the format `<S3endpoint>` or `<S3endpoint>/<S3region>`. • SFTP - the hostname of the SFTP server

`path`	The location for the backups on your remote storage target:
	• S3 - the name of your S3 bucket and path. Valid examples:
	`bucket`
	`bucket/path`
	`bucket/lots/of/paths`
	• SFTP - the full absolute path of the folder on the SFTP server, beginning with `/`.

`port`	The port on the remote storage target. Defaults are: • S3 - 443. • SFTP - 22.
`protocol`	The backup type. Specify one of the following values: • `sftp` - For backups to a remote SFTP server. • `objstore` - For backups to a remote S3 object-store. • `local` - To store backups locally, in the portal subsystem's PVCs. Note: If a disaster occurs your portal PVCs might be lost or corrupted, so it is recommended to use one of the remote backup server options.
`backupCerts`	**S3 storage only:** The secret that contains your S3 store's CA certificate, that you create in step: 2.
`backups3URIStyle`	**S3 storage only:** `backups3URIStyle` indicates whether URIs to your S3 backup should specify a host or a path value. Default is `host`. Valid values: `host` and `path`. Some custom S3 providers require URI style to be set to `path`. For example, MinIO supports both `host` and `path` style setup. You can create a MinIO S3 server to accept only `path` style client communications. Important: Contact your custom S3 administrator before you configure this field. If not properly configured, an upstream custom S3 object-store can reject connections.

`schedule`	The schedule for how often automatic Developer Portal backups are run. The format for the schedule is any valid cron string. The time zone for backups is Coordinated Universal Time.
	Valid for all backup types: S3, SFTP, and local.
	
	`spec:`
	`  portalBackup:`
	`  ...`
	`  schedule: '0 2 * * *'`
	
	If the schedule property is omitted, the default schedule of one backup per day is implemented.

`backupRecordDays`	The `backupRecordDays` setting denotes the number of days that backup records (backups that exist on the remote backup server) are shown when you list your remote backups. It is defaulted to 30 days.

6. Update the `PortalCluster` CR backup in your Infrastructure configuration backup.
   If you are using Cloud Pak for Integration or OpenShift with the top-level CR, also update your `APIConnectCluster` CR backup.

What to do next

Run an on-demand backup to confirm that your backup configuration is correct, see Running an on-demand backup of the portal database.
[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Running an on-demand backup of the portal database

Deploy the **PortalBackup** CR to initiate a backup of the portal database.

About this task

Note: If you are taking a portal database backup, you must also take a management database backup at the same time. Management and portal databases must be kept in sync.
Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Procedure

1. Decide which type of backup you want to take:
   - **all**: backs up the Developer Portal system and all its sites.
   - **system**: backs up the Developer Portal system only.
   - **site**: backs up a specific Developer Portal site.

   Note: Developer Portal system backup includes all the portal configuration that is not specific to sites, such as IP allowlist.
2. Identify the name of the portal cluster that you want to backup:

   ```
   kubectl -n <portal namespace> get PortalCluster
   ```

3. Create a file called portalbackup_cr.yaml and paste in the following text:

   ```
   apiVersion: portal.apiconnect.ibm.com/v1beta1
   kind: PortalBackup
   metadata:
     generateName: portal-bup-
   spec:
     type: <type>
     portalCluster: <portal cluster name>
     crType: create
     siteName: <site to backup>
     comment: "<comment>"
   ```

   where:
   - **type** is the backup type that you decided in step 1.
   - **portalCluster** is the cluster name that you identified in step 2.
   - **siteName** is the name of the portal site that you want to backup. This property applies only when backup type of **site** is specified. Valid settings are:
     - Site UUID or URL - back up the specified site only.
     - **installed** - backups all installed sites.
   - **comment** is a text comment to help you identify the reason for the backup, for example: "pre-upgrade backup".
4. Create the **PortalBackup** CR from the portalbackup_cr.yaml file:

   ```
   kubectl -n <portal namespace> create -f portalbackup_cr.yaml
   ```

5. Verify that the backup is running with:

   ```
   $ kubectl -n <portal namespace> get portalbackup --sort-by=.status.backupId
   ```

   The expected output for an **all** type backup is:

   ```
   NAME                    ID                TASK ID  STATUS     TYPE     CR TYPE   CLUSTER    AGE     COMMENT
   portal-record-89dgz     20200526.142449   n/a      Ready      system   record    portal     55m
   portal-record-89dgz     20200526.142458   n/a      Ready      site     record    portal     54m
   p1-bup-st4l2                              n/a      Ready      all      create    portal     56m     y
   ```

   For every on-demand backup triggered at least two **PortalBackup** CRs are created:
   - **Create**. The **create** CR type is the first CR to be created. The **create** CR does not create the portal database backup itself, but is responsible for creating **record** type **PortalBackup** CRs, which are representations of individual backups.
   - **Record**. The **record PortalBackup** CR has two types:
     - **System**. The **System** record type represents one system backup file, containing the portal configuration that applies to all sites
     - **Site**. The **Site** record type represents a backup file for one site. Site backups contain any Drupal customizations made to the site.
6. You can get a detailed view of a specific backup CR by using the command:

   ```
   kubectl -n <portal namespace> get portalbackup <backup name> -o yaml
   ```

   Example output for a **create** type backup CR:

   ```
   apiVersion: portal.apiconnect.ibm.com/v1beta1
   kind: PortalBackup
   metadata:
     creationTimestamp: "2020-10-01T10:00:16Z"
     generateName: portal-bup-
     generation: 1
     name: portal-bup-g66gv
     namespace: default
     resourceVersion: "8940"
   ```

```
  selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/default/portalbackups/portal-bup-g66gv
  uid: b1d5b295-b966-48f2-b6ef-dfcd1c499741

Observe the property showing the filename of the backup: portal_system_backup-20230922.083722.tar.gz.

What to do next

Take a database backup of the management subsystem that your portal is registered with. You must have management and portal database backups that are in sync with each other: Running an on-demand backup of the management database.

Managing your remote portal database backups

How to manage your remote portal database backup resources.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.
When you run the command `kubectl get portalbackup -o wide`, you see a list of all the backups that ran during the past 30 days:

```
NAME                  ID                TASK ID      STATUS   TYPE     CR TYPE   CLUSTER   AGE   COMMENT   FILENAME
my-backup-f91ms       n/a               20b47fe090f5 Ready    all      create    portal    58m
portal-record-2vcgs   20231105.181212   n/a          Ready    system   record    portal    55m
_portal_system_backup-20231105.181212.tar.gz
portal-record-9j8lt   20231104.095949   n/a          Ready    system   record    portal    55m

portal-record-c4d5s   20231106.121946   n/a          Ready    site     record    portal    25m             portal.fyre-ci-
162245-master.fyre.ibm.com@ibm@api-connect-catalog-2-20231106.121946.tar.gz
portal-record-c7p5q   20231106.110330   n/a          Ready    system   record    portal    55m
_portal_system_backup-20231106.110330.tar.gz
portal-record-f5h2h   20231106.115701   n/a          Ready    system   record    portal    55m
_portal_system_backup-20231106.115701.tar.gz
```

`PortalBackup` CRs with `CR TYPE` of `create` can be ignored. Create type CRs are generated when a backup is triggered manually, they are used to generate the `record` type `PortalBackup` CRs that hold the actual portal database backup. You can delete `create` type CRs after its corresponding `record` type CRs are created.
You can filter out `create` type CRs from `kubectl get portalbackup` output with **grep**:

```
kubectl get portalbackup | grep record
```

When you create a backup of type 'all', the following `PortalBackup` CRs are created:

- `PortalBackup` CR of type 'system' that contains the portal system data, which is everything in the portal database that applies to all sites.
- For each site, a `PortalBackup` CR of type 'site' that contains all the data that is related to the site, such as Drupal site customizations.

For example if your portal has three sites, you get 4 `PortalBackup` CRs:

```
portal-record-222cg   20230108.010033               Ready    system   record
portal-record-22xdc   20230108.010035               Ready    site     record
portal-record-245j7   20230108.010037               Ready    site     record
portal-record-246hm   20230108.010040               Ready    site     record
```

The portalBackupRecordDays property defines how many `PortalBackup` CRs are shown in the output of `kubectl get portalbackup`. The default is the last 30 days of CRs.

Portal performance can be negatively impacted if you have too many `PortalBackup` CRs, particularly during an upgrade. If you are taking backups more frequently than once a day, or have many sites, then it is recommended to reduce the `portalBackupRecordDays` property to a lower value. You can still keep as many backups as you want on your remote server, but if they don't have a corresponding `PortalBackup` CR then you must restore them using the .tgz file name or `timestamp`, see: Restoring from a portal database backup.

Portal backup .tgz files

For most operations that involve portal database backups, you work with a backup ID or a datestamp of the backup you want to restore, but some operations might require identifying the backup file name.

Portal database backups are contained in compressed archived files (TGZ), the name of the file is shown in the last column of the `kubectl get portalbackup -o wide` output:

```
kubectl -n <portal namespace> get portalbackup -o wide
```

Example output:

```
NAME                  ID                TASK ID      STATUS   TYPE     CR TYPE   CLUSTER   AGE   COMMENT   FILENAME
portal-record-2vcgs   20231105.181212   n/a          Ready    system   record    portal    55m
_portal_system_backup-20231105.181212.tar.gz
```

Restoring from a portal database backup

Create a `PortalRestore` CR to restore your management database.

Before you begin

Restore the management database backup on your management subsystem first. Restore from a management database backup that was taken at the same time as the portal database backup you want to restore.

About this task

- Portal database backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a portal database backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see Migrating from v10 to v10 on a different form factor.
- Two data center disaster recovery deployments have extra backup and restore considerations. Review Backup and restore requirements for a 2DCDR deployment before you follow the instructions in this topic.

Three types of restore are available:

- **`all`**: restores the Developer Portal system and all the sites that are contained in the specified database backup.
- **`system`**: restores the Developer Portal system but not any sites from the database backup.
- **`site`**: restores a specific Developer Portal site from the database backup.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **`kubectl`** command. On OpenShift, use the equivalent **`oc`** command in its place.

Procedure

1. Identify the portal backup that you want to restore with:

   ```
   $ kubectl -n <portal namespace> get portalbackup -o wide --sort-by=.status.backupId | grep record
   ```

   Example output:

   ```
   NAME                   ID                 TASK ID       STATUS   TYPE     CR TYPE   CLUSTER   AGE   COMMENT   FILENAME
   portal-record-2vcgs    20231105.181212    n/a           Ready    system   record    portal    55m
   _portal_system_backup-20231105.181212.tar.gz
   portal-record-9j81t    20231104.095949    n/a           Ready    system   record    portal    55m
   _portal_system_backup-20231104.095949.tar.gz
   portal-record-c4d5s    20231106.121946    n/a           Ready    site     record    portal    25m             portal.fyre-ci-
   162245-master.fyre.ibm.com@ibm@api-connect-catalog-2-20231106.121946.tar.gz
   portal-record-c7p5q    20231106.110330    n/a           Ready    system   record    portal    55m
   _portal_system_backup-20231106.110330.tar.gz
   portal-record-f5h2h    20231106.115701    n/a           Ready    system   record    portal    55m
   _portal_system_backup-20231106.115701.tar.gz
   ```

   Note: You can restore the portal database only from backups where the **`CR TYPE`** is **`record`**.
   You can get more information on a specific backup with:

   ```
   kubectl -n <portal namespace> get portalbackup <backup name> -o yaml
   ```

2. Verify that the backup you want to restore exists on the remote server.
3. Identify the name of the portal cluster that you want to restore to:

   ```
   kubectl -n <portal namespace> get PortalCluster
   ```

4. Create a file called portalrestore_cr.yaml. The text that you paste into the YAML file depends on the type of backup you want to restore:
   - Restore type **`all`**. Restore the full portal database, including all sites:

     ```
     apiVersion: portal.apiconnect.ibm.com/v1beta1
     kind: PortalRestore
     metadata:
       generateName: portal-restore-
     spec:
       type: all
       portalCluster: <portal cluster name>
       dryRun: <true or false>
       timestamp: <datestamp>
       priorityList:
         - <most important site to restore>
         - <second most important site to restore>
     ```

     where:
     - **`portalCluster`** is the cluster name that you identified in step 3.
     - **`dryRun`** if you want to test restore of the backup, without overwriting your portal, set **`dryRun`** to **`true`**.
     - **`timestamp`** specify a timestamp to retrieve the backup from. The nearest backup, searching backwards from this timestamp, is used. Format is *'YYYYMMDD.HHMMSS'*, or set to **`now`** to restore the most recent backup.
     - **`priorityList`** Prioritizes the restore of specific site. The sites are restored in the order in which they are listed in **`priorityList`**, followed by any remaining unlisted sites. Example contents:

       ```
       priorityList:
           - production.site.com
           - test.site.com
       ```

       If you have no preference for site restore priority, then omit this property.
   - Restore type **`site`**. Restore backup of a particular site:

     ```
     apiVersion: portal.apiconnect.ibm.com/v1beta1
     kind: PortalRestore
     metadata:
       generateName: portal-restore-
     spec:
       type: site
     ```

```
  portalCluster: <portal cluster name>
  siteName: <portal site to restore>
```

where:

- `portalCluster` is the cluster name that you identified in step 3.
- `siteName` is either:
  - The UUID or URL of the site you want to restore, for example: `myportal.com`, in this case the latest backup of this site restored.
  - The backup ID of the backup that contains the site that you want to restore.
  - `all` - restore all sites in the latest backup.
  - `installed` - restore from the latest backup only sites that currently exist. For cases where your backup contains site backups for sites that no longer exist on your portal.
  - Backup .tgz file name. For example: site-1234.tgz restores the site from the backup file name. The file name of the backup is shown in the last column of the `kubectl get portalbackup -o wide` output.

- Restore type `system`. Restore portal system backup, but no sites.

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
  generateName: portal-restore-
spec:
  type: system
  portalCluster: <portal cluster name>
  systemName: <backup ID>
```

where:

- `portalCluster` is the cluster name that you identified in step 3.
- `systemName` is either:
  - The backup ID of a portal backup CR. You can restore only portal database backups that are of `type` system and `crType` record.
  - Filename of the backup's .tgz file. Restores the system from the specified backup file name. The file name of the backup is shown in the last column of the `kubectl get portalbackup -o wide` output.
  - `latest`: restores from latest system backup that is available.

5. Optional: If the `API` hostname of your management subsystem platform API changed since taking the backup you are restoring, then add the property `customPlatformApiHostname` to your portalrestore_cr.yaml file and set it to the new platform API hostname of the management subsystem. For example:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
  generateName: portal-restore-
spec:
  ...
  customPlatformApiHostname: mgmt.platformapi.host
  ...
```

6. Create the `PortalRestore` CR from the portalrestore_cr.yaml file:

```
kubectl -n <portal namespace> create -f portalrestore_cr.yaml
```

7. Verify that the restore is running with:

```
kubectl -n <portal namespace> get portalrestore
```

Example output for a restore type of `all`:

```
NAME                   TYPE    TASK ID            STATUS    MESSAGE                                                    AGE
portal-restore-2xsgl   all     t3wz85rxz61jam92   Running   Sites Restored: 2, Sites Failed: 0, Sites Pending: 1
```

Example output for a restore type of `system`:

```
NAME                   TYPE     TASK ID             STATUS   MESSAGE                                                CLUSTER
AGE
portal-restore-xtjjt   system   yrwtcw5ult08p786    Ready    Please describe the CR to see the full message.   portal
72s
```

8. To see more information about the restore, run:

```
kubectl -n <portal namespace> get portalrestore <restore name> -o yaml
```

Example output:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
  creationTimestamp: "2020-11-11T10:14:39Z"
  generateName: portal-restore-
  generation: 1
  name: portal-restore-8f4c5
  namespace: portal
  resourceVersion: "1497597"
  selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/portal/portalrestores/portal-restore-8f4c5
  uid: 5a70b657-d998-4989-b9b6-8480e986311d
spec:
  siteName: "20200526.090209"
  portalCluster: portal
  type: site
status:
  backupId: ""
  commentLeft: ""
  conditions:
  - lastTransitionTime: "2020-11-11T10:14:39Z"
```

```
    reason: RestoreFailed

    type: Warning
  fullBackupName: ""
  id: bybyibd99wxtmkmk
  message: ""
```

9. When the restore completes **RestorePortal** CR shows Ready state, regardless of whether the restore was successful or not.

```
NAME                    TYPE    TASK ID            STATUS    MESSAGE                                                    AGE
portal-restore-2xsgl    all     t3wz85rxz61jam92   Ready    Sites Restored: 3, Sites Failed: 0, Sites Pending: 0
```

10. If a site fails to restore, check for messages in the restore description:

```
kubectl -n <portal namespace> get portalrestore <restore name> -o yaml
```

Also, check the logs of the admin container in the **www** pod:

```
kubectl -n <portal namespace> logs <portal www pod> -c admin
```

Recovering from a disaster

Reinstall the portal subsystem by using your infrastructure configuration backup, then restore the portal database backup.

Before you begin

To successfully recover the portal subsystem, you must have the following backups:

- Infrastructure configuration backup.
- Portal database backup.

About this task

- Portal subsystem backups can be restored in the same environment where they were taken, or in a different environment that has the same network configuration, endpoints, and deployment profile. You cannot restore a portal subsystem backup in a different network environment, form factor, or deployment profile. If you want to move your API Connect deployment to a different form factor or change endpoints, see Migrating from v10 to v10 on a different form factor.
  Note: If your management platform API endpoint changed since the portal database backup was created, you can update this setting during portal database restore by using the **customPlatformApiHostname** property in the **PortalRestore** CR. This is the only exception to the identical endpoints requirement. See Restore portal database.
- When you restore a portal database backup, you must first restore the database backup of the management subsystem that the portal is registered with. Portal and management databases must remain in sync.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Procedure

1. Reinstall your portal subsystem by using the YAML files from your Infrastructure configuration backup.
   Your infrastructure configuration backup consists of:
   - Portal CR YAML: portal_cr_backup.yaml.
   - Portal database encryption secret: portal_enc_key_backup.yaml.
   - Portal backup server credentials secret: ptl-backup-secret_backup.yaml.
   - If required, the portal backup server CA certificate secret: portal_custom_s3_ca.yaml.

- If you customized any portal certificates, a YAML file of the secret for each customized certificate. For example: portalWeb_secret_backup.yaml.

a. Create the database encryption secret with the portal_enc_key_backup.yaml:

```
kubectl -n <portal namespace> apply -f portal_enc_key_backup.yaml
```

b. Create the backup credential secrets with your ptl-backup-secret_backup.yaml file:

```
kubectl -n <portal namespace> apply -f ptl-backup-secret_backup.yaml
```

c. Create the S3 CA secret (if required) with:

```
kubectl -n <portal namespace> apply -f portal_custom_s3_ca.yaml
```

d. Create the secrets for any customized certificates from their backup files:

```
kubectl -n <portal namespace> apply -f <custom certificate secret backup file>
```

e. Install the portal subsystem. Follow the installation procedures for your platform: Deployment procedures, but use the settings from the `spec` section of your portal_cr_backup.yaml file.
Note:
- Cloud Pak for Integration users: Many of the portal configuration settings can be configured in Cloud Pak for Integration Platform UI. You do not need to edit the YAML directly.

2. Restore your portal database: Restoring from a portal database backup.

Troubleshooting portal database backup and restore

Troubleshoot problems with portal database backups and restores.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.
Check the status section of the PortalBackup or PortalRestore CR:

```
kubectl -n <portal namespace> get <portalbackup/portalrestore> <bup-name/restore-name> -o yaml
```

Example output:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalRestore
metadata:
  creationTimestamp: "2020-05-26T13:10:46Z"
  generateName: portal-restore-
  generation: 1
  name: portal-restore-x2bf9
  namespace: portal
  resourceVersion: "1493471"
  selfLink: /apis/portal.apiconnect.ibm.com/v1beta1/namespaces/portal/portalrestores/portal-restore-x2bf9
  uid: 9f6a1e22-55ab-4595-8b98-bdfaec40d58c
spec:
  portalCluster: portal
  type: site
status:
  backupId: ""
  commentLeft: ""
  conditions:
  - lastTransitionTime: "2020-05-26T13:10:49Z"
    message: |
      Please provide a site to restore. To restore all sites use value 'all' in the CR
    status: Failed
    type: Ready
  fullBackupName: ""
  id: ""
  message: ""
```

Check operator pod logs. Look for information in the logs of the `ibm-apiconnect` pod:

- Locate the `ibm-apiconnect` pod with:

  ```
  kubectl get pods -n <namespace-of-portal-subsystem>
  ```

- View the logs with:

  ```
  kubectl logs <ibm-apiconnect-pod-NAME> -n <namespace-of-portal-subsystem>
  ```

Common problems with backup and restore

These are some frequent issues that can cause backup or restore to fail:

- Invalid login credentials for your remote backup server. Check that the username and password that you configured in your subsystem database backup settings is correct.
- The user does not have write permissions on the backup server. Check that the username you configured in your subsystem database backup settings has write permission to the specified backup path.
- Remote backup server storage full. Check your remote backup server and if the storage is full either extend the storage space or delete older backups.
- No network access to the remote backup server. Check that you can communicate with your remote backup server from your API Connect environment.
- TLS handshaking failure with the remote backup server. If your remote backup server has a self-signed CA certificate, check that this certificate is trusted by your API Connect deployment, see the database backup configuration steps for your subsystem for more information.

Backing up and restoring the analytics subsystem

How to configure analytics backups and recover from a disaster.

For information about analytics backup, restore, and disaster recover, refer to Configuring analytics backups.

Backing up and restoring on OpenShift top-level CR

How to backup and restore your top-level CR deployment of API Connect

- **Backing up your OpenShift top-level CR API Connect deployment**
- **Disaster recovery on OpenShift top-level CR**

Backing up your OpenShift top-level CR API Connect deployment

About this task

A full API Connect backup consists of:

- Infrastructure configuration backup: The infrastructure configuration backup includes everything that you configure for API Connect in your deployment environment, such as:
  - Custom resource (CR) YAML files.
  - Custom certificates.
  - Encryption secrets.
  - Backup secrets.
- Subsystem database backups: The management, portal, and analytics subsystems all have their own databases that must be backed up:
  - Management database contains everything users configure in the management UIs, REST API, toolkit CLI, and portal sites (excluding Drupal customizations).
  - Portal database contains all portal and site customizations.
  - Analytics database contains all API event data, and the settings of analytics features configured in the management UIs.

Procedure

1. Take a backup of your top-level CR:

   ```
   oc -n <namespace> get ApiconnectCluster -o yaml > apic_cr_backup.yaml
   ```

2. Take backups of each subsystem, following the documented steps:
   - Backing up and restoring the management subsystem
   - Backing up and restoring the developer portal
   - Backing up and restoring the analytics subsystem

Disaster recovery on OpenShift top-level CR

About this task

To recover your API Connect deployment, follow the steps in this topic along with the instructions for Installing with the top-level CR on OpenShift.

Note: The steps that are detailed in this topic use the Kubernetes `kubectl` command, which does work on OpenShift, but if you want you can replace `kubectl` with the OpenShift equivalent command: `oc`.

Procedure

1. Create the management subsystem Kubernetes secrets from the backup YAML files that you created in Management infrastructure configuration backup.
   a. Create the database encryption secret with the management_enc_key_backup.yaml file:

      ```
      kubectl -n <management namespace> apply -f management_enc_key_backup.yaml
      ```

   b. Create the backup credential secret with your mgmt-backup-secret_backup.yaml file:

      ```
      kubectl -n <management namespace> apply -f mgmt-backup-secret_backup.yaml
      ```

   c. Create the credential secrets with the <credential secret>_backup.yaml files you saved in step 5 of Taking a management infrastructure configuration backup:

      ```
      kubectl -n <management namespace> apply -f <credential secret backup file>
      ```

   d. Set the object-store CA secret (if required) from your backup file:

      ```
      kubectl -n <management namespace> apply -f mgmt_custom_objstore_ca.yaml
      ```

   e. Create the secrets for any customized certificates from their backup files:

```
kubectl -n <management namespace> apply -f <custom certificate secret backup file>
```

2. Create the portal subsystem Kubernetes secrets from the backup YAML files that you created in Portal infrastructure configuration backup.
   a. Create the database encryption secret with the portal_enc_key_backup.yaml:

   ```
   kubectl -n <portal namespace> apply -f portal_enc_key_backup.yaml
   ```

   b. Create the backup credential secrets with your ptl-backup-secret_backup.yaml file:

   ```
   kubectl -n <portal namespace> apply -f ptl-backup-secret_backup.yaml
   ```

   c. Create the S3 CA secret (if required) with:

   ```
   kubectl -n <portal namespace> apply -f portal_custom_s3_ca.yaml
   ```

   d.
   e. Create the secrets for any customized certificates from their backup files:

   ```
   kubectl -n <portal namespace> apply -f <custom certificate secret backup file>
   ```

3. Re-create the analytics secrets that you backed up. See Backup analytics secrets.
4. Prepare the top-level CR for your replacement API Connect, copy and paste the **spec** section from your apic_cr_backup.yaml file.
5. Create the API Connect deployment from the YAML file.
   Refer to the installation steps in Installing with the top-level CR on OpenShift.
   Wait for all subsystems to be created and ready. Monitor the installation progress with the command:

   ```
   oc -n <namespace> get ApiconnectCluster
   ```

6. Restore the subsystem databases:
   a. Restoring the management database with a backup ID.
   Verify that the restoration completed successfully and that the management subsystem is Ready, then proceed to the next step and restore the portal subsystem.

   b. Restoring from a portal database backup.
   Use the restore type **all** to ensure that you restore the complete subsystem and all portal sites.

   c. Restoring the analytics database.

Backing up and restoring on Cloud Pak for Integration and OpenShift top-level CR

How to backup and restore all API Connect subsystem in a Cloud Pak for Integration, or OpenShift top-level CR deployment

- **Backing up your Cloud Pak for Integration API Connect deployment**
  How to backup your API Connect configuration and subsystem databases.
- **Recovering from a disaster on Cloud Pak for Integration**
  Prepare your Cloud Pak for Integration environment for installation of the replacement API Connect deployment. Install API Connect. Restore the database backups of each subsystem.

Backing up your Cloud Pak for Integration API Connect deployment

How to backup your API Connect configuration and subsystem databases.

About this task

A full API Connect backup consists of:

- Infrastructure configuration backup: The infrastructure configuration backup includes everything that you configure for API Connect in your deployment environment, such as:
  - Custom resource (CR) YAML files.
  - Custom certificates.
  - Encryption secrets.
  - Backup secrets.
- Subsystem database backups: The management, portal, and analytics subsystems all have their own databases that must be backed up:
  - Management database contains everything users configure in the management UIs, REST API, toolkit CLI, and portal sites (excluding Drupal customizations).
  - Portal database contains all portal and site customizations.
  - Analytics database contains all API event data, and the settings of analytics features configured in the management UIs.

To backup your Cloud Pak for Integration or OpenShift top-level CR deployment, backup the infrastructure configuration and databases of each subsystem:

Procedure

1. Save the CP4I credentials secret.

   ```
   oc -n <namespace> get secret <instance_name>-cp4i-creds -o yaml > cp4i_credentials_secret_backup.yaml
   ```

   Edit the saved YAML file and remove both the **ownerReferences** subsection and the **selfLink** property, and then save the updated file.

2. If you did not change the cloud administrator password after installation, backup the cloud admin password secret.

```
oc -n <namespace> get secret <instanceName>-mgmt-admin-pass -o jsonpath="{.data.password}" | base64 -d
```

3. Backup the API Connect CR.

```
oc -n <namespace> get ApiconnectCluster -o yaml > apic_cr_backup.yaml
```

4. Follow the backup steps for each subsystem.
   - Backing up and restoring the management subsystem
   - Backing up and restoring the developer portal
   - Backing up and restoring the analytics subsystem

   Important: Ensure that you backup all subsystem CRs, and not just the top-level CR. The subsystem CRs contain additional information about each subsystem, which is required for disaster recovery.

Recovering from a disaster on Cloud Pak for Integration

Prepare your Cloud Pak for Integration environment for installation of the replacement API Connect deployment. Install API Connect. Restore the database backups of each subsystem.

About this task

To recover from a disaster, re-create your API Connect deployment, referring to the backup files and artifacts you took when you followed the backup process: Backing up your Cloud Pak for Integration API Connect deployment.

Note: Your recovery installation of Cloud Pak for Integration must include the Platform UI if your original deployment used it. In addition, the CR must use the same settings as in the original deployment.

Procedure

Preparing the Cloud Pak for Integration environment.

1. Prepare your Cloud Pak for Integration environment for deploying API Connect as explained in the appropriate version of the Cloud Pak for Integration documentation.
   After you prepare your environment, return to this procedure to configure the installation CR, deploy API Connect, and then restore the subsystem database backups to your API Connect subsystems.

2. Create management and portal encryption secrets from your backups of these secrets.
   a. Create the management database encryption secret.

   ```
   oc -n <namespace> apply -f management_enc_key_backup.yaml
   ```

   where management_enc_key_backup.yaml is the encryption secret backup that you created in step 2.c of Taking a management infrastructure configuration backup

   b. Create the portal database encryption secret.

   ```
   oc -n <namespace> apply -f portal_enc_key_backup.yaml
   ```

   where portal_enc_key_backup.yaml is the encryption secret backup that you created in step 2.c of Taking a portal infrastructure configuration backup.

3. Create the Cloud Pak for Integration credentials secret.

```
oc -n <namespace> apply -f cp4i_credentials_secret_backup.yaml
```

where cp4i_credentials_secret_backup.yaml is the credentials backup file that you created in step 1 of Backing up your Cloud Pak for Integration API Connect deployment.

4. Generate the Kubernetes secret for each subsystem's database backups, by using the backup files that you created for each subsystem.

   a. `oc -n <namespace> apply -f mgmt-backup-secret_backup.yaml`

   where mgmt-backup-secret_backup.yaml was created in step 3 on Taking a management infrastructure configuration backup.

   b. `oc -n <namespace> apply -f ptl-backup-secret_backup.yaml`

   where ptl-backup-secret_backup.yaml was created in step 3 on Taking a portal infrastructure configuration backup.

   c. `oc -n <namespace> apply -f analytics-backup-secret_backup.yaml`

   where analytics-backup-secret_backup.yaml was created in Configuring analytics backups.

5. Create each of the management client application credential secrets.
   Run the following command to apply each secret, by using the backup YAML files that you created in step 5 of Taking a management infrastructure configuration backup.

```
oc -n <namespace> apply -f <secretName>.yaml
```

Example:

```
atmCredentialSecret: management-atm-cred
consumerToolkitCredentialSecret: management-ccli-cred
consumerUICredentialSecret: management-cui-cred
designerCredentialSecret: management-dsgr-cred
discoveryCredentialSecret: management-discovery-cred
governanceCredentialSecret: management-governance-cred
juhuCredentialSecret: management-juhu-cred
toolkitCredentialSecret: management-cli-cred
uiCredentialSecret: management-ui-cred
```

Prepare draft API Connect installation YAML file.

6. Log in to the IBM Cloud Pak Platform UI and create a draft API Connect YAML.
   In this step, you complete the initial steps for deploying API Connect in Cloud Pak for Integration, but you do not begin the actual installation until step 8. Instead, you update the draft API Connect YAML to match the API Connect YAML you backed up in Backing up your Cloud Pak for Integration API Connect deployment.

   a. Log in to the Platform UI.
   b. On the home page, click Create an instance.
   c. Select the API management tile and click Next.
   d. On the Create an instance of API management page, select the deployment type, and click Next.
      Choose the same deployment type that you used when you originally deployed API Connect.

   e. On the deployment settings page, click the YAML tab to edit the installation CR in YAML format.

Update draft API Connect YAML with values from your CR backup files.

7. Refer to your CR backup files apic_cr_backup.yaml and *<subsystem>*_cr_backup.yaml to update the properties in your draft YAML.
   a. Set **`metadata.name`** to the value from your backup apic_cr_backup.yaml.
   b. Set the management and portal encryption secrets.
      Set **`spec.<subsystem>.encryptionSecret.secretName`** with the secrets you created in step 2, as shown in the following example:

      ```
      spec:
        management:
          encryptionSecret:
            secretName: mgmt-enc-key
        portal:
          encryptionSecret:
            secretName: portal-enc-key
      ```

   c. Set each of the credential secrets in **`spec.management`** section, to the secrets you created in step 5.
      Example:

      ```
      spec:
        management:
          customApplicationCredentials:
          - name: atm-cred
            secretName: management-atm-cred
          - name: ccli-cred
            secretName: management-ccli-cred
          - name: cui-cred
            secretName: management-cui-cred
          - name: dsgr-cred
            secretName: management-dsgr-cred
          - name: governance-cred
            secretName: management-governance-cred
          - name: juhu-cred
            secretName: management-juhu-cred
          - name: cli-cred
            secretName: management-cli-cred
          - name: ui-cred
            secretName: management-ui-cred
      ```

   d. If you are restoring your deployment in a different data center, explicitly set your endpoints to prevent auto-generation of different endpoints.
      If you are restoring your deployment in a different data center, the endpoints that are used in your original deployment must be the same in your new data center. The Platform UI in Cloud Pak for Integration auto-generates the endpoints if they are left empty in the YAML, therefore ensure that you explicitly set the endpoints in the CR to match what is set in your <subsystem>_cr_backup.yaml files.

      For example:

      ```
      apiManagerEndpoint:
            annotations:
              cert-manager.io/issuer: prod-ingress-issuer
              haproxy.router.openshift.io/timeout: 240s
            hosts:
              - name: prod-api-manager.example.com
              secretName: prod-be787dd3-api-manager
      ```

   e. Set the subsystem database backup and restore settings to match what you have in apic_cr_backup.yaml.
      The **`spec.<subsystem name>.databaseBackup`** sections for each subsystem contain the database backup settings.

Start API Connect deployment.

8. On the deployment page, install API Connect by clicking Create.
   Wait for all subsystems to be created and ready. Monitor the installation progress with the command:

   ```
   oc -n <namespace> get ApiconnectCluster
   ```

9. Restore the subsystems' database backups in the following sequence:
   a. Restoring the management database with a backup ID.
      Verify that the restoration completed successfully and that the management subsystem is Ready, then proceed to the next step and restore the portal subsystem.

   b. Restoring from a portal database backup.
      Use the restore type **`all`** to ensure that you restore the complete subsystem and all portal sites.

   c. Restoring the analytics database.
      Use the restore type **`replace`** to ensure that you restore all analytics data.

10. Force the configurator to run again.

The cluster will still not be ready after restore at this stage because the configurator has yet to successfully complete. For the configurator to run again, delete the associated job so that a new pod starts running:

a. Run the following command to get the list of jobs:

```
oc get jobs -n <APIC_namespace>
```

b. Run the following command to determine the name of your API Connect instance:

```
oc get apiconnectcluster -n <APIC_namespace>
```

c. Run the following command to delete the configurator job:

```
oc -n <APIC_namespace> delete job <instance_name>-configurator
```

11. Verify that the recovery was successful:
    a. Ensure that you can log in to the Cloud Manager UI.
    b. Verify that your provider organizations exist.
    c. Ensure that you can log in to each portal site.
    d. Ensure that the analytics dashboard contains your restored analytics data.

Maintaining a two data center deployment

How to maintain a two data center disaster recovery (DR) deployment on Kubernetes and OpenShift, including information about normal operation, failure handling, and recovery.

See the following topics for information about failure handling, backup, upgrade, and removing a 2DCDR deployment.

For general information about two data center disaster recovery in API Connect, see Two data center warm-standby deployment on Kubernetes and OpenShift.

- **Key concepts of 2DCDR and failure scenarios**
  Understand how API Connect 2DCDR works and what to do when a data center fails.
- **Failing over to the warm-standby**
  How to complete service failover in a 2DCDR deployment on Kubernetes, OpenShift, and Cloud Pak for Integration, for API Connect.
- **Backup and restore requirements for a 2DCDR deployment**
  Points to consider when you configure database backup and restore settings on a two data center disaster recovery (2DCDR) deployment.
- **Removing a two data center deployment**
  Convert your 2DCDR deployment to a stand-alone deployment on Kubernetes, OpenShift, and Cloud Pak for Integration.
- **Verifying replication between data centers**
  How to verify that your API Connect data is replicating to your warm-standby data center.

Key concepts of 2DCDR and failure scenarios

Understand how API Connect 2DCDR works and what to do when a data center fails.

This topic discusses the concepts around the operation and maintenance of an API Connect 2DCDR deployment. For information on the planning and installation of a 2DCDR deployment, see: Two data center warm-standby deployment on Kubernetes and OpenShift.

Failover

Failover is a manual operation that requires updating the active management, portal, or both subsystems to become warm-standby, and the warm-standby subsystems to become active. The typical situations for completing a failover operation are:

- Operational failover: Where your active API Connect subsystems and data center are functioning normally, but you want to switch data centers for operational reasons, or to test the failover process.
  In this scenario, the active management and portal subsystems are converted to warm-standby first, and then the original warm-standby subsystems are converted to active.
- System down failover: Where your active data center, or the API Connect subsystems in that data center are in a failed state, and you must failover to the warm-standby to restore your API Connect service.
  In this scenario, the subsystems in the warm-standby data center are converted to active, and the network connectivity to and from the failed active subsystems is disabled - until it is possible to convert them to warm-standby.

Important:

- In all scenarios, an active-active configuration must be avoided. An active-active configuration is where the API Connect subsystems in both data centers are configured as active. This situation is commonly known as a split-brain. An active-active configuration means that the subsystem databases in each data center diverge from each other, and two management subsystems are both attempting to manage the other API Connect subsystems.
- When the active management subsystem is set to warm-standby, all data is deleted from its database. The management data from the new active (what was the warm-standby) is replicated to the new warm-standby data center. Do not set the active data center to warm-standby until you confirm that data replication is

working, see: Verifying replication between data centers, or you have backups of your management data.

Reverting to a stand-alone deployment

If you want to revert to a stand-alone API Connect deployment, before you start the process, ensure that the data center where you choose to keep API Connect is set to active.

- When API Connect is reverted to be a stand-alone deployment on the warm-standby data center, all management and portal data is deleted from that data center. It becomes an empty stand-alone deployment.
- When API Connect on the active data center is reverted to be a stand-alone deployment, all management and portal data remains.

Failure scenarios

The action that you should take when a failure occurs depends on the type of failure and which data center the failure occurs in:

API Connect failure in the active data center.
When the active data center is still working correctly, and still has connectivity to the warm-standby data center, but API Connect is not working correctly:

1. It might be possible to recover API Connect on the active data center. Review the troubleshooting documentation:
   - Troubleshooting two data center replication problems.
   - Installation troubleshooting.
   - Troubleshooting operational problems.
2. Follow the failover steps to make the warm-standby the active data center. If your failed data center cannot be changed to warm-standby, then disable network connectivity to and from it, to avoid an active-active situation if the data center recovers unexpectedly.
3. Gather API Connect logs from the failed data center and open a support request: Gathering logs.
4. Do not restore the network connectivity to and from the API Connect subsystems in the failed data center until they are set to warm-standby.

Complete active data center failure
When the active data center has a failure, and API Connect is not accessible, follow these steps:

1. Disable the network connections from and to your active subsystems. Network disablement is required to prevent an active-active scenario if your failed data center recovers before you can change it to warm-standby.
2. Follow the failover steps to convert the warm-standby data center to active: Failing over to the warm-standby.
3. Do not restore the network connectivity to and from the API Connect subsystems in the failed data center until they are set to warm-standby.

Network failure that prevents API calls or user access to Management and Portal subsystems on active data center.
In this scenario, the API Connect 2DCDR deployment is working correctly, but unusable because the active data center is not accessible for API calls or for Management and Portal UI/CLI/REST API users.

1. Complete a failover, setting warm-standby to active, and the active to warm-standby: Failing over to the warm-standby.

API Connect failure on the Warm-standby data center
Where the API Connect pods on the warm-standby data center are not running as expected.

1. Review the troubleshooting documentation Troubleshooting two data center replication problems.
2. Gather API Connect logs from the failed data center and open a support case: Gathering logs.

Warm-standby data center failure
The data center where API Connect was running as warm-standby fails. In this case when the data center is recovered:

1. Verify that API Connect is running correctly as warm-standby and that the data from the active is replicated to it: Verifying replication between data centers.

Network failure between data centers
When the network connection between data centers is recovered, verify that 2DCDR database replication resumes: Verifying replication between data centers.

Management 2DCDR operational modes and statuses

The management CR `status` section includes information on the current 2DCDR mode of the management subsystem, and its status. The status section is included in the output of

```
kubectl -n <namespace> get mgmt -o yaml
```

```
...
status:
...
  haMode: active
  ...
  haStatus:
```

Table 1. 2DCDR Management subsystem operational modes (`status.haMode`)

Operational mode	Description
`active`	The subsystem pods are ready and in the correct disaster recovery state for the active data center.
`passive`	The subsystem pods are ready and in the correct disaster recovery state for the warm-standby data center.
`standalone`	The management subsystem is not configured for 2DCDR.

Table 2. Management subsystem 2DCDR statuses (`status.haStatus`)

`status.haStatus`	Description
Pending	2DCDR initial state.
Warning	Replication is failing.
Ready	Replication is running.
Error	Error in 2DCDR configuration.

status.haStatus	Description
PeerNotReachable	The subsystem cannot contact the subsystem on the other site, and so replication is failing.
BlockedWarmStandbyConversion	The warm-standby subsystem is in **Blocked** state, waiting for other site to become active. This state occurs when user converts existing warm-standby to active.
PromotionBlocked	Current warm-standby site promotion to active is blocked
ReadyForPromotion	Current warm-standby site is ready for promotion
PGStateSetupBlocked	Appears on active data center only. This status means that warm-standby did not initiate operator-level communication to the active yet. The active management subsystem is blocking incoming database-level connection attempts from the warm-standby.

Portal 2DCDR operational states

The portal subsystem has various transitory states that it passes through during startup and failover. The current 2DCDR operational state can be observed from the CR status section, for example:

```
kubectl get ptl -o yaml

...
status:
...
  haMode: active
  ...
  haStatus:
```

Table 3. 2DCDR Portal subsystem operational states

Operational state	Description
progressing to active	Pods are progressing to the active state, but the subsystem is not capable of serving traffic.
progressing to active (ready for traffic)	At least one pod of each type is ready for traffic. The dynamic router can be linked to this service.
active	The subsystem pods are ready and in the correct disaster recovery state for the active data center.
progressing to passive	Pods are progressing to the warm-standby state. The subsystem is not capable of serving traffic.
progressing to passive (ready for traffic)	At least one pod of each type is ready for traffic.
passive	The subsystems are ready and in the correct disaster recovery state for the warm-standby data center.
progressing to down	Portal is preparing to do a factory reset. This happens to the warm-standby portal when the **multiSiteHA** section is removed.

Failing over to the warm-standby

How to complete service failover in a 2DCDR deployment on Kubernetes, OpenShift, and Cloud Pak for Integration, for API Connect.

Before you begin

Ensure that you have read and understand the 2DCDR concepts and reviewed the failure scenarios that are described in Key concepts of 2DCDR and failure scenarios. Do not proceed with the failover operation until you confirm that failover is the correct course of action for your situation.

About this task

Be aware of the following important points:

- The first step in the process is to convert the active data center to warm-standby. When the active data center is converted to warm-standby, all data is deleted from the active data center's management database, to be replaced by data that is copied from the warm-standby when it becomes active.
  Do not proceed with failover if you suspect the warm-standby data center also has problems, and you are unsure it has the most recent management data. See Verifying replication between data centers, and consider restoring your active site from backup instead of attempting a failover: Backup and restore requirements for a 2DCDR deployment.
- In all scenarios, an active-active configuration must be avoided. An active-active configuration is where the API Connect subsystems in both data centers are configured as active. This situation is commonly known as a split-brain. An active-active configuration means that the subsystem databases in each data center diverge from each other, and two management subsystems are both attempting to manage the other API Connect subsystems.
- If the active data center failure prevents you from converting it to warm-standby, then you must disable the network connectivity to and from the failed management and portal subsystems on this data center, to prevent an accidental active-active situation if your failed data center recovers unexpectedly.
- If you are doing an operational failover, the process causes a temporary management and portal UI outage, until the new warm-standby completes the conversion to active.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place. If you are using a top-level CR you must edit the **multiSiteHA** section for the subsystem in the top-level CR, instead of directly in the subsystem CRs.

Procedure

- **Management subsystem failover**
  In these example steps, DC1 is the active data center and DC2 is the warm-standby data center.

  To complete a failover from DC1 to DC2, you first set DC1 to warm-standby before you set DC2 to active. This order is required to prevent an active-active situation.

  1. Set the DC1 management subsystem to be warm-standby.

- On Kubernetes and OpenShift individual subsystem CR deployments: Create a file called demote-to-warm-standby.yaml, and paste in the following text:

  ```
  metadata:
    annotations:
      apiconnect-operator/dr-data-deletion-confirmation: "true"
  spec:
    multiSiteHA:
      mode: passive
  ```

  Apply the updates that are specified in the demote-to-warm-standby.yaml file to your management CR:

  ```
  kubectl patch mgmt <mgmt cr name> --type merge --patch "$(cat demote-to-warm-standby.yaml)"
  ```

- On Cloud Pak for Integration and OpenShift top-level CR deployments: Create a file called demote-to-warm-standby.yaml, and paste in the following text:

  ```
  metadata:
    annotations:
      apiconnect-operator/dr-data-deletion-confirmation: "true"
  spec:
    management:
      multiSiteHA:
        mode: passive
  ```

  Apply the updates that are specified in the demote-to-warm-standby.yaml file to your API Connect CR:

  ```
  oc patch apiconnectcluster <apic cr name> --type merge --patch "$(cat demote-to-warm-standby.yaml)"
  ```

Note: If API Connect on DC1 is down, such that you can't set it to be warm-standby, you must ensure that the network connectivity to and from the management subsystem in DC1 is disabled, to prevent an accidental active-active situation if DC1 recovers unexpectedly. Do not restore network connectivity until DC1 is set to warm-standby.

2. Run the following command on DC1 to check that the management subsystem HA mode is no longer `active`:

   ```
   kubectl get mgmt -o yaml
   ```

   During transition to warm-standby, the `status.haMode` shows `BlockedWarmStandbyConversion`. You can monitor the transition with:

   ```
   kubectl get mgmt -o=jsonpath='{"Status: "}{.status.phase}{"\n - HA Mode: "}{.status.haMode} {"\n - Ha Status: "}
   {.status.haStatus[?(@.status=="True")].type}{"\n"}'
   ```

   ```
   Status: Blocked
    - HA Mode: BlockedWarmStandbyConversion
    - Ha Status: BlockedWarmStandbyConversion
   ```

3. Change the DC2 management subsystem from warm-standby to active.
   Check the DC2 management subsystem `haStatus`:

   ```
   kubectl get mgmt -o yaml
   ```

   ```
   status
     ...
     haMode: ReadyForPromotion
       haStatus:
         ...
         type: ReadyForPromotion
     ...
   ```

   wait until the `haStatus` shows `ReadyForPromotion` before proceeding. You can monitor the transition with:

   ```
   kubectl get mgmt -o=jsonpath='{"Status: "}{.status.phase}{"\n - HA Mode: "}{.status.haMode} {"\n - Ha Status: "}
   {.status.haStatus[?(@.status=="True")].type}{"\n"}'
   ```

   ```
   Status: Blocked
    - HA Mode: ReadyForPromotion
    - Ha Status: ReadyForPromotion
   ```

   - On Kubernetes and OpenShift individual subsystem CR deployments:
     Edit the DC2 management CR:

     ```
     kubectl edit mgmt
     ```

     Change `spec.multiSiteHA.mode` to `active`:
   - On Cloud Pak for Integration and OpenShift top-level CR deployments:
     Edit the DC2 `APIConnectCluster` CR:

     ```
     oc edit apiconnectcluster
     ```

     Change `spec.management.multiSiteHA.mode` to `active`.

4. Run the following command on both data centers to confirm when management subsystem failover is complete:

   ```
   kubectl get mgmt
   ```

   Example output:

   ```
   production-mgmt   n/n   Running   10.0.x.y   10.0.x.y        Management is ready. HA status Ready - see HAStatus in
   CR for details
   ```

   Note: Failover can take 10 minutes or more to complete. If failover does not complete, you can check the API Connect operator pod log for errors (search for the word "Multi").

5. Update your dynamic router to redirect all traffic to DC2 instead of DC1. Until the DC2 site becomes `active`, the UIs might not be operational.
6. Cloud Pak for Integration only: Check the APIConnectCluster CR status:

```
oc get apiconnectcluster
```

If the status returns `Warning`:

```
NAME          READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE                                        AGE
production    4/5     Warning   10.0.8.0   10.0.8.0-7178        Warning - see status condition for details   7d9h
```

then check the status conditions:

```
oc get apiconnectcluster <apiconnectcluster cr name> -o json | jq -r '.status.conditions[] | select(.status=="True")'
```

If the output shows the following condition:

```
{
  "lastTransitionTime": "2024-05-29T18:15:16Z",
  "message": "an error occured while running job apic/production-configurator",
  "reason": "na",
  "status": "True",
  "type": "Warning"
}
```

then run the following command on your new active data center:

```
oc -n <namespace> delete job -l app.kubernetes.io/component=configurator
```

where *<namespace>* is the namespace of your APIConnectCluster.

- **Developer Portal subsystem failover**
  In these example steps, DC1 is the active data center and DC2 is the warm-standby data center.

  If you have multiple Developer Portal services, you must repeat these steps for each Developer Portal subsystem that you want to failover.

  1. Set the DC1 Developer Portal subsystem to be warm-standby.
     - On Kubernetes and OpenShift individual subsystem CR deployments:
       Edit the DC1 `PortalCluster` CR:

       ```
       kubectl edit ptl
       ```

       Change `multiSiteHA.mode` to `passive`.
     - On Cloud Pak for Integration and OpenShift top-level CR deployments:
       Edit the DC1 `APIConnectCluster` CR:

       ```
       oc edit apiconnectcluster
       ```

       Change `spec.portal.multiSiteHA.mode` to `passive`.

     Note: If API Connect on DC1 is down, such that you can't set it to be warm-standby, you must ensure that the network connectivity to and from the portal subsystem in DC1 is disabled, to prevent an accidental active-active situation if DC1 recovers unexpectedly. Do not restore network connectivity until DC1 is set to warm-standby.
  2. Run the following command on DC1 to check the Developer Portal subsystem status:

     ```
     kubectl get ptl -o yaml
     ```

     Continue to the next step when `status.haMode` is set to `progressing to passive`, or any of the `passive` states.
     For example:

     ```
     status:
       ...
       haMode:                              progressing to passive
       ...
     ```

  3. Change the DC2 Developer Portal subsystem from warm-standby to active.
     - On Kubernetes and OpenShift individual subsystem CR deployments:
       Edit the DC2 `PortalCluster` CR:

       ```
       kubectl edit ptl
       ```

       Change `spec.multiSiteHA.mode` to `active`.
     - On Cloud Pak for Integration and OpenShift top-level CR deployments:
       Edit the DC2 `APIConnectCluster` CR:

       ```
       oc edit apiconnectcluster
       ```

       Change `spec.portal.multiSiteHA.mode` to `active`.
  4. Update your dynamic router to redirect all traffic to DC2 instead of DC1.
  5. Run the following command to check that the Developer Portal services on DC1 and DC2 are ready for traffic:

     ```
     kubectl get ptl -o yaml
     ```

     The services are ready for traffic when the `status.haMode` is set to `passive` on DC1, and is set to `active` on DC2.
- **Failover of both management and portal subsystems**
  Failover the management subsystem first, followed by the portal subsystem.

  How long it takes to complete the failover varies, and depends on hardware speed, network latency, and the size of the databases. Approximate timings are:

  For the management subsystem:
  - `warm-standby` to `active`: 5 minutes
  - `active` to `warm-standby`: 15 minutes

  For the Developer Portal:
  - `warm-standby` to `active`: 15 - 40 minutes
  - `active` to `warm-standby`: 10 minutes

What to do next

If the original active data center was successfully converted to warm-standby, then verify that replication is working: Verifying replication between data centers. If replication is working, you can either:

- Revert your 2DCDR deployment to the original active and warm-standby data center designations. To revert your deployment, follow the same failover steps in this topic.
- Do nothing, and continue with your current active and warm-standby data center designations.

If your failed data center cannot be updated to warm-standby, then ensure that the network links to and from your management and portal subsystems in the failed data center are disabled. If the network links remain enabled, then an accidental active-active situation might occur if your failed data center recovers unexpectedly.

When you are able to recover the failed data center, ensure that the management and portal subsystems are set to warm-standby before you restore the network connectivity to prevent an active-active situation.
Note: The longer your original active data center was in a failed state, the longer data replication takes when it is recovered to warm-standby.
If you expect your failed data center to be down for a long time, then convert your active data center to a stand-alone deployment. See Removing a two data center deployment.

Backup and restore requirements for a 2DCDR deployment

Points to consider when you configure database backup and restore settings on a two data center disaster recovery (2DCDR) deployment.

In a 2DCDR deployment, the backup requirements are different for the portal and management databases.

Management database 2DCDR backup and restore requirements

- Different remote backup locations must be specified for each data center.
- Both active and warm-standby management subsystems run the scheduled database backup job.
- For manual database backups, always run the warm-standby backup first.
- For scheduled database backups, configure the warm-standby's backup to run one minute before the active site's backup.
- To restore the management database, you must convert both sites to standalone (non-2DCDR) before you can run the restore process.
- To restore a management database backup, follow these steps:
  1. Make each management data center a stand-alone API Connect deployment: Temporary conversion to stand-alone.
  2. Restore the database backup to your previously active data center: Restoring from a management database backup.
  3. Restore the 2DCDR configuration to the management CR in the restored data center. Ensure that the `multiSiteHA` section defines the data center as the active.
  4. Restore the 2DCDR configuration to the other data center. Ensure that the `multiSiteHA` section defines the data center as the warm-standby (passive).
  5. The management database takes some time to synchronize across the data centers. To confirm that replication is working, see: Verifying replication between data centers.

  Note: If you want to restore the backup to your previously warm-standby data center, and make that the active, then after step 1 follow these steps:
  1. To prevent an active-active situation, disable network connectivity to the management subsystem in your previously active data center.
  2. Restore the backup to your previously warm-standby data center.
  3. Restore the 2DCDR configuration to the management CR in the restored data center. Ensure that the `multiSiteHA` section defines the data center as the active.
  4. Restore the 2DCDR configuration to the management CR to the other data center. Ensure that the `multiSiteHA` section defines the data center as the warm-standby (passive).
  5. Enable network connectivity to your new warm-standby data center.
  6. The management database takes some time to synchronize across the data centers. To confirm that replication is working, see: Verifying replication between data centers.

Portal subsystem 2DCDR backup requirements

- The backup settings for both the active and warm-standby portal must be identical.
- Only the active data center portal takes backups. On failover, the backup job of the new warm-standby is disabled, and the backup job of the new active is enabled.
- Restore portal database backups on the active data center.

Configuring database backups

The steps for configuring database backups for both subsystems are the same as for a single API Connect deployment, but keep the additional 2DCDR requirements in mind when following the steps in Backing up, restoring, and disaster recovery.

Related concepts

- Two data center warm-standby deployment on Kubernetes and OpenShift

Removing a two data center deployment

Convert your 2DCDR deployment to a stand-alone deployment on Kubernetes, OpenShift, and Cloud Pak for Integration.

Ensure that you have read and understand the concepts of 2DCDR. See Two data center warm-standby deployment on Kubernetes and OpenShift and Key concepts of 2DCDR and failure scenarios.

Note: When you convert the warm-standby data center to stand-alone, all data is deleted from its management database. Data deletion is to prevent an active-active situation, where the warm-standby attempts to communicate with existing portal, gateway, and analytics subsystems that the formally active data center is also communicating with.
Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place. If you are using a top-level CR you must edit the `multiSiteHA` section for the subsystem in the top-level CR, instead of directly in the subsystem CRs.
Note: 2DCDR system endpoints must be changed to standalone when converting to standalone to avoid new health check issues.

Temporary conversion to stand-alone

Some API Connect maintenance operations, such as management database restore require that 2DCDR is temporarily disabled.

To convert a 2DCDR management or portal subsystem to stand-alone, follow these steps:

1. Take a backup of your current 2DCDR configuration, by backing up the subsystem CRs.
   a. On Kubernetes and OpenShift where individual subsystem CRs are used, take the management subsystem CR backup with:

      ```
      kubectl get mgmt -o yaml > mgmt_<dr status>_2dcdr_backup.yaml
      ```

      and take the portal CR backup with:

      ```
      kubectl get ptl -o yaml > portal_<dr status>_2dcdr_backup.yaml
      ```

      where *<dr status>* is the current 2DCDR status of the subsystem, either active or warm-standby.
   b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

      ```
      kubectl get apiconnectcluster -o yaml > apic_<dr status>_2dcdr_backup.yaml
      ```

      where *<dr status>* is the current 2DCDR status of the subsystem, either active or warm-standby. The `APIConnectCluster` CR contains the 2DCDR settings for both management and portal subsystems.
2. Remove the 2DCDR configuration from the management subsystem. The steps to take are different for active and warm-standby:
   a. Active management subsystem:
      i. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

      ```
      kubectl patch managementcluster <mgmt cr name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
      ```

      ii. On Cloud Pak for Integration and OpenShift where the top-level CR is used:

      ```
      kubectl patch apiconnectcluster <apic cr name> --type json -p='[{"op": "remove", "path":
      "/spec/management/multiSiteHA"}]'
      ```

   b. Warm-standby management subsystem:
      To convert the management subsystem from warm-standby to stand-alone, you must acknowledge acceptance of this in an annotation in the management CR. The steps to convert warm-standby management to stand-alone are:
      i. On Kubernetes and OpenShift where individual subsystem CRs are used, create a file that is called remove-2dcdr-config-from-warm-standby.yaml, and paste in the following text:

      ```
      metadata:
        annotations:
          apiconnect-operator/dr-data-deletion-confirmation: "true"
      spec:
        multiSiteHA: null
      ```

      Apply the file to your management CR with:

      ```
      kubectl patch managementcluster <mgmt cr name> --type merge --patch "$(cat remove-2dcdr-config-from-warm-
      standby.yaml)"
      ```

      ii. On Cloud Pak for Integration and OpenShift where the top-level CR is used, create a file that is called remove-2dcdr-config-from-warm-standby.yaml and paste in the following text:

      ```
      metadata:
        annotations:
          apiconnect-operator/dr-data-deletion-confirmation: "true"
      spec:
        management:
          multiSiteHA: null
      ```

      Apply the file to your top-level CR with:

      ```
      kubectl patch apiconnectcluster <mgmt cr name> --type merge --patch "$(cat remove-2dcdr-config-from-warm-
      standby.yaml)"
      ```

3. Remove the 2DCDR configuration from the portal subsystem:
   a. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

      ```
      kubectl patch portalcluster <portal CR name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
      ```

      Delete the `spec.multiSiteHA` section.
   b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

      ```
      kubectl patch apiconnectcluster <apic cr name> --type json -p='[{"op": "remove", "path":
      "/spec/portal/multiSiteHA"}]'
      ```

4. Complete the maintenance operation that required the temporary conversion to stand-alone, such as management database restore.
5. Restore the 2DCDR configuration by adding back the `multiSiteHA` sections to your subsystem CRs. You can restore these sections by copying the `multiSiteHA` sections from the backup files you took in step 1, and pasting them into the corresponding CRs:
   a. On Kubernetes and OpenShift where individual subsystem CRs are used:
      i. Edit the management CR:

      ```
      kubectl edit mgmt
      ```

and paste in the `multiSiteHA` section from your backup mgmt_*<dr status>*_2dcdr_backup.yaml.

ii. Edit the portal CR:

```
kubectl edit ptl
```

and paste in the `multiSiteHA` section from your backup portal_*<dr status>*_2dcdr_backup.yaml.

b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, edit the top-level CR:

```
kubectl edit apiconnectcluster
```

and in the `spec.management.multiSiteHA`, paste in the contents from the corresponding `multiSiteHA` sections of your apic_*<dr status>*_2dcdr_backup.yaml

Permanently revert to stand-alone

If you want to revert to a single data center topology:

1. Decide which data center you want to keep. If this data center is not the current active data center, then complete the failover operation to make it the active: Failing over to the warm-standby.
2. Remove the 2DCDR configuration section from the management subsystem CR on the active data center.
   a. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

   ```
   kubectl patch managementcluster <mgmt cr name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
   ```

   b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

   ```
   kubectl patch apiconnectcluster <apic cr name> --type json -p='[{"op": "remove", "path":
   "/spec/management/multiSiteHA"}]'
   ```

3. Remove the 2DCDR configuration from the portal subsystem:
   a. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

   ```
   kubectl patch portalcluster <portal CR name> --type json -p='[{"op": "remove", "path": "/spec/multiSiteHA"}]'
   ```

   Delete the `spec.multiSiteHA` section.
   b. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

   ```
   kubectl patch apiconnectcluster <apic cr name> --type json -p='[{"op": "remove", "path":
   "/spec/portal/multiSiteHA"}]'
   ```

4. The next action that you take depends on what you want to do with your warm-standby data center:
   a. If you want to permanently revert to a single data center topology, then uninstall API Connect on the warm-standby data center. See: Uninstalling API Connect.
   b. Leave your warm-standby as it is, in case you decide to revert your stand-alone data center to a 2DCDR active.
   c. Convert your warm-standby subsystems to stand-alone. This operation erases all data from the management and portal databases.
   To convert the management subsystem from warm-standby to stand-alone, you must acknowledge acceptance of this in an annotation in the management CR. The steps to convert warm-standby management to stand-alone are:
      i. On Kubernetes and OpenShift where individual subsystem CRs are used, create a file that is called remove-2dcdr-config-from-warm-standby.yaml, and paste in the following text:

      ```
      metadata:
        annotations:
          apiconnect-operator/dr-data-deletion-confirmation: "true"
      spec:
        multiSiteHA: null
      ```

      Apply the file to your management CR with:

      ```
      kubectl patch managementcluster <mgmt cr name> --type merge --patch "$(cat remove-2dcdr-config-from-warm-
      standby.yaml)"
      ```

      ii. On Cloud Pak for Integration and OpenShift where the top-level CR is used, create a file that is called remove-2dcdr-config-from-warm-standby.yaml and paste in the following text:

      ```
      metadata:
        annotations:
          apiconnect-operator/dr-data-deletion-confirmation: "true"
      spec:
        management:
          multiSiteHA: null
      ```

      Apply the file to your top-level CR with:

      ```
      kubectl patch apiconnectcluster <mgmt cr name> --type merge --patch "$(cat remove-2dcdr-config-from-warm-
      standby.yaml)"
      ```

   To convert portal from warm-standby to stand-alone, manually remove the `spec.multiSiteHA` section from the portal CR:
      i. On Kubernetes and OpenShift where individual subsystem CRs are used, run:

      ```
      kubectl edit ptl
      ```

      Delete the `spec.multiSiteHA` section.
      ii. On Cloud Pak for Integration and OpenShift where the top-level CR is used, run:

      ```
      kubectl edit apiconnectcluster
      ```

      Delete the `spec.portal.multiSiteHA` section.

Verifying replication between data centers

How to verify that your API Connect data is replicating to your warm-standby data center.

The management and portal UIs are not accessible on the warm-standby data center, so it is not possible to check that data replication is working by logging in to the UIs. Instead, you can verify that the warm-standby management and portal databases are in sync with command-line operations.
Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes `kubectl` command. On OpenShift, use the equivalent `oc` command in its place.

Verifying Management replication

The management CR reports a warning if it detects a problem with management data replication:

```
kubectl get mgmt

NAME          READY   STATUS    VERSION      RECONCILED VERSION   MESSAGE
AGE
management    n/n     Warning   10.0.8.0-0   10.0.8.0-0           Management is ready. HA Status Warning - see HAStatus in CR
for details   8m59s

kubectl get mgmt -o yaml

...
status:
  haStatus
    {
      "lastTransitionTime": "2023-03-31T19:47:08Z",
      "message": "Replication not working",
      "reason": "na",
      "status": "True",
      "type": "Warning"
    }
```

If the warning persists, then see Troubleshooting a two data center deployment.
To verify replication by creating new data on the active and checking that it is copied to the warm-standby, follow these steps:

1. Login to the Cloud Manager UI.
2. Create a local user registry called **`2dcdrtest`**: Configuring a Local User Registry.
3. Run the following command in your warm-standby data center to query the management database for the new user registry:

   ```
   kubectl exec -n <namespace> `kubectl -n <namespace> get po -l role=primary -o name` -- bash -c "psql -U postgres apim -c
   \"select name,created_at from user_registry where name = '2dcdrtest'\""
   ```

   Expected output is:

   ```
   Defaulted container "database" out of: database, set-libpq-certs (init)
      name     |       created_at
   ------------+------------------------
    2dcdrtest | <date and time when step 2 was done>
   (1 row)
   ```

   If **`2dcdrtest`** is returned and has a creation time consistent with when you did step 2, then replication is working. If it is not returned, then either replication is not working, or the data is not yet replicated. If an older creation date is returned, then it's possible the registry was not deleted after a previous check, in which case delete the registry and repeat this test. If replication is not working, follow the 2DCDR troubleshooting steps: Troubleshooting a two data center deployment.
4. Return to the Cloud Manager UI, and delete the **`2dcdrtest`** user registry.

Verifying Portal replication

Follow these steps to verify that the portal database is replicating from the active data center to the warm-standby data center.

1. In the active data center, identify the active db pod:

   ```
   kubectl get pods -n <namespace> | grep "<active site name>-db"
   ```

   Example output:

   ```
   <portal instance name>-<active site name>-db-0                                                    2/2     Running     0
   22h
   ```

   where *<active site name>* is the **`siteName`** property from the portal CR on your active data center. The active data center db pods have 2 containers, so show a status of 2/2. A three replica deployment has three db pods and you can pick any one of them for the next step.
2. In the active data center, run the following command:

   ```
   kubectl exec -ti -n <namespace> <active portal db pod> -c db -- bash -ic "dbstatus 2>&1 | grep Last | sed 's/.*committed:
   \([0-9]*\).*/\1/'"
   ```

   Example output:

   ```
   355175
   ```

   where *<active portal db pod>* is the pod name that is returned from step 1. The command returns a number.
3. In the warm-standby data center, identify the warm-standby db pod:

   ```
   kubectl get pods -n <namespace> | grep "<warm-standby site name>-db"
   ```

   Example output:

```
<portal instance name>-<warm-standby site name>-db-0                    2/2     Running     0
22h
```

where *<warm-standby site name>* is the `siteName` property from the portal CR on your warm-standby data center. The warm-standby data center db pods have 1 container, so show a status of 1/1. A three replica deployment has three db pods and you can pick any one of them for the next step.

4. In the warm-standby data center, run the following command:

```
kubectl exec -ti -n <namespace> <passive portal db pod> -c db -- bash -ic "dbstatus 2>&1 | grep Last | sed 's/.*committed:
\([0-9]*\).*/\1/'"
```

Example output:

```
355495
```

where *<passive portal db pod>* is the pod name that is returned from step 3. The command returns a number.

5. The numbers that are returned from steps 2 and 4 represent the portal database's last committed transaction number. When the active data center commits a new transaction the number is incremented, this update is replicated to the warm-standby data center. If replication is working the number that is returned from the warm-standby data center should always be close to the number that is returned from the active data center. It is unlikely to be the same number that is returned, unless you are able run step 4 and step 2 at precisely the same time.
6. Repeat steps 2 and 4 several times to confirm that the warm-standby number is keeping up with the active number. If the number returned from the warm-standby data center is far behind, or ahead of the number that is returned from the active, then there is likely to be a replication problem, see Troubleshooting a two data center deployment.

Synchronizing the ingress-ca certificates between sites

The X.509 CA certificate that is used for TLS communication between the API Connect deployments in each data center is referred to as the `ingress-ca` X.509 certificate. This certificate is stored in the `ingress-ca` **secret** in both data centers, and it must be the same in each data center for 2DCDR to function.

The cert-manager has a separate object that is referred to as the `ingress-ca` Kubernetes cert-manager certificate object. Cloud Pak for Integration and OpenShift top-level CR deployments has the `ingress-ca` Kubernetes cert-manager certificate object in both data centers. Kubernetes and OpenShift individual subsystem installations, has the `ingress-ca` Kubernetes cert-manager certificate object in only one of the data centers, the data center that was the original active data center when 2DCDR was first configured.

Ingress-ca on Kubernetes and OpenShift individual subsystem installations

In Kubernetes and OpenShift individual subsystem CR installations, the `ingress-ca` Kubernetes cert-manager certificate object exists on only one of the data centers in a 2DCDR deployment. The `ingress-ca` **secret** object exists in both data centers and must contain the same certificate string:

```
kubectl -n <namespace> get secret ingress-ca -o yaml

apiVersion: v1
data:
  ca.crt: <long cert string>
  tls.crt: <long cert string>
  tls.key: <long cert string>
kind: Secret
...
```

To identify the data center that has the `ingress-ca` Kubernetes cert-manager certificate object, run:

```
kubectl -n <namespace> get cert ingress-ca

   NAME         READY   SECRET       AGE
   ingress-ca   True    ingress-ca   30h
```

Note: If the data center that has the `ingress-ca` Kubernetes cert-manager certificate object is in a failed state and is unrecoverable, a new `ingress-ca` Kubernetes cert-manager certificate object can be created on the active data center by using the `ingress-ca` certificate section of the installation YAML file: `helper_files/ingress-issuer-v1.yaml`:

```
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  name: ingress-ca
  labels: {
    app.kubernetes.io/instance: "management",
    app.kubernetes.io/managed-by: "ibm-apiconnect",
    app.kubernetes.io/name: "ingress-ca"
  }
spec:
  secretName: ingress-ca
  commonName: "ingress-ca"
  usages:
  - digital signature
  - key encipherment
  - cert sign
  isCA: true
  duration: 87600h # 10 years
  renewBefore: 720h # 30 days
  privateKey:
    rotationPolicy: Always
  issuerRef:
    name: selfsigning-issuer
    kind: Issuer
```

Synchronizing the `ingress-ca` X.509 certificate across data centers

Follow these steps to extract your **ingress-ca** X.509 certificate from your source data center and prepare it for application on your target data center:

1. Extract the **ingress-ca secret** from your source data center to a file called **new-ca-issuer-secret.yaml**:

   ```
   kubectl get secret ingress-ca -o yaml -n <namespace>  > new-ca-issuer-secret.yaml
   ```

2. Edit the **new-ca-issuer-secret.yaml** file and remove the **creationTimestamp**, **resourceVersion**, **uid**, **namespace**, and **managedFields**. Remove the labels and annotations sections completely. The resulting contents should include the **ingress-ca** X.509 certificate, and the secret name:

   ```
   apiVersion: v1
   data:
     ca.crt: <long cert string>
     tls.crt: <long cert string>
     tls.key: <long cert string>
   kind: Secret
   metadata:
     name: ingress-ca
   type: kubernetes.io/tls
   ```

3. Copy the **new-ca-issuer-secret.yaml** to the target data center.

Follow these steps to apply the extracted **ingress-ca** X.509 certificate on your target data center:

1. To apply the **new-ca-issuer-secret.yaml** file, run:

   ```
   kubectl apply -f new-ca-issuer-secret.yaml -n <namespace>
   ```

2. Regenerate all **ingress-ca** end-entity certificates:

   ```
   kubectl get secrets -n <namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-
   manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n
   <namespace>
   ```

   All affected pods should automatically restart. For more information about regenerating certificates, see: Renewing cert-manager controlled certificates.

Troubleshooting a two data center deployment

What to check when a 2DCDR deployment is not starting or not replicating data.

Typical causes of 2DCDR failures are network problems between data centers, TLS certificate mismatches, or environmental problems on one of the data centers.

Note: For OpenShift users: The steps that are detailed in this topic use the Kubernetes **kubectl** command. On OpenShift, use the equivalent **oc** command in its place.

Check that API Connect pods are running

Confirm that all the pods are ready and running:

- To check portal, run:

  ```
  kubectl get ptl -n <namespace>
  ```

  ```
  NAME                          READY                                  STATUS    VERSION    RECONCILED VERSION   MESSAGE
  AGE
  <portal instance name>        <ready pods>/<total number of pods>    Running   10.0.5.x   10.0.5.x-xxxx        Serving 1
  site   14d
  ```

- To check management, run:

  ```
  kubectl get mgmt -n <namespace>
  ```

  ```
  NAME                          READY                                  STATUS    VERSION    RECONCILED VERSION   AGE
  <management instance name>    <ready pods>/<total number of pods>    Running   10.0.5.x   10.0.5.x-xxxx        14d
  ```

The number of *<ready pods>* must match the *<total number of pods>*. If not all the pods are in ready state, run

```
kubectl get <mgmt or ptl> -n <namespace> -o yaml
```

and check the **status.conditions** output, for example:

```
  conditions:
  - lastTransitionTime: "2022-09-27T21:37:21Z",
    message: "Management installation in progress. Not all services are ready, pending services: analytics-proxy, apim, client-
downloads-server, juhu, ldap, ...",
    reason: na
    status: "True"
    type: Pending
```

Also, check which pods are not running with:

```
kubectl get pods -n <namespace>
```

and review their logs:

```
kubectl logs <pod name> -n <namespace>
```

Note: The warm-standby management subsystem has fewer pods than the active management subsystem. The active and warm-standby portal subsystems have the same number of pods.

Check the multiSiteHA sections of the management and portal CRs

Run `kubectl describe` on your management and portal CRs to confirm that the `multiSiteHA` specification and status sections of the CR are as expected. For example, on the warm-standby management CR you should see:

```
kubectl describe mgmt -n <namespace>

...
spec:
  Multi Site HA:
    Mode:  passive
    Replication Endpoint:
      Annotations:
        cert-manager.io/issuer:  ingress-issuer
      Hosts:
        Name:                mgmt-replication.apps.example.com
        Secret Name:         mgmt-replication-server
    Replication Peer FQDN:  mgmt-replication.apps.example.com
    Tls Client:
      Secret Name:  mgmt-replication-client
...
Status
...
  Ha Mode:                                passive
...
  Multi Site HA:
    Remote Site Deployment Name:  management
    Remote Site Name:             passive
    Remote UUID:                  c736b702-b1ab-4fe2-b132-9c9d3b3a3bd3.9f986be1-14fc-4b3a-8eee-094217ce361e
    Replication Peer:             https://mgmt-replication.apps.example.com/
```

Check that the `Hosts` and `Replication Peer` properties are set correctly in the `multiSiteHA` section, and that the hostnames resolve correctly in each data center.

Check the `ingress-ca` X.509 certificates match

Replication fails if both data centers do not have the same X.509 certificate in their `ingress-ca` secrets. Run the following command in both data centers to see the X.509 certificate, and check that the output is the same:

```
openssl x509 -noout -fingerprint -sha256 -in <(kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk
'{print $2}' | base64 -d)
```

If you do not have the `openssl` command available, you can instead run only the `kubectl` part, which produces a larger output:

```
kubectl get secret ingress-ca -n <namespace> -o yaml | grep "^  tls.crt:" | awk '{print $2}' | base64 -d
```

if the outputs are different, follow these steps to synchronize the certificates:

1. If you installed API Connect on Kubernetes or OpenShift using individual subsystem CRs, determine which data center has the `ingress-ca` Kubernetes cert-manager certificate object:

   ```
   kubectl get certificates -n <namespace> | grep ingress-ca
   ```

   this is your source data center.
   Note: If no certificates are returned when you run:

   ```
   kubectl get certificates -n <namespace> | grep ingress-ca
   ```

   on either data center, then create a new `ingress-ca` Kubernetes cert-manager certificate object can be created on the active data center by using the `ingress-ca` certificate section of the installation YAML: `helper_files/ingress-issuer-v1.yaml`:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: ingress-ca
     labels: {
       app.kubernetes.io/instance: "management",
       app.kubernetes.io/managed-by: "ibm-apiconnect",
       app.kubernetes.io/name: "ingress-ca"
     }
   spec:
     secretName: ingress-ca
     commonName: "ingress-ca"
     usages:
     - digital signature
     - key encipherment
     - cert sign
     isCA: true
     duration: 87600h # 10 years
     renewBefore: 720h # 30 days
     privateKey:
       rotationPolicy: Always
     issuerRef:
       name: selfsigning-issuer
       kind: Issuer
   ```

   The `ingress-ca` certificate can be lost in certain scenarios, such as redeployment of one of the data centers as warm-standby after a failure.

2. If you installed API Connect on Cloud Pak for Integration, use the current active data center as the source data center, and the warm-standby as the target data center.

3. Extract the **ingress-ca secret** from your source data center to a file called **new-ca-issuer-secret.yaml**:

   ```
   kubectl get secret ingress-ca -o yaml -n <namespace>  > new-ca-issuer-secret.yaml
   ```

4. Edit the **new-ca-issuer-secret.yaml** file and remove the **creationTimestamp**, **resourceVersion**, **uid**, **namespace**, and **managedFields**. Remove the labels and annotations sections completely. The resulting contents should include the **ingress-ca** X.509 certificate, and the secret name:

   ```
   apiVersion: v1
   data:
     ca.crt: <long cert string>
     tls.crt: <long cert string>
     tls.key: <long cert string>
   kind: Secret
   metadata:
     name: ingress-ca
   type: kubernetes.io/tls
   ```

5. Copy the **new-ca-issuer-secret.yaml** to the target data center.

Follow these steps to apply the extracted **ingress-ca** X.509 certificate on your target data center:

1. To apply the **new-ca-issuer-secret.yaml** file, run:

   ```
   kubectl apply -f new-ca-issuer-secret.yaml -n <namespace>
   ```

2. Regenerate all **ingress-ca** end-entity certificates:

   ```
   kubectl get secrets -n <namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-
   manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n
   <namespace>
   ```

   All affected pods should automatically restart. For more information about regenerating certificates, see: Renewing cert-manager controlled certificates.

Check the operator and tunnel pod logs

The API Connect operator pod manages the 2DCDR deployment. The tunnel pods manage the communication between data centers.

Check the logs of the API Connect operator pod and search for the text "multi" to see any errors that are related to 2DCDR. For example:

```
kubectl logs <ibm-apiconnect operator pod> -n <operator namespace> | grep -i multi
```

The *<ibm-apiconnect operator pod>* has **ibm-apiconnect** in its name, and might be in a different namespace to your API Connect operand pods.

Check the logs of your API Connect **tunnel** pods. These pods always have **tunnel** in their name. For example:

```
kubectl logs portal-tunnel-0 -n <namespace> --since=10m
```

```
...
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 2022-12-02T12:27:33.786Z    INFO    tls     incoming
request {"remote-addr": "10.254.20.144:55042", "uri": "/portal-active-db-0/3060"}
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 2022-12-02T12:27:33.786Z    INFO    tls     connect to
upstream        {"remote-addr": "10.254.20.144:55042", "uri": "/portal-active-db-0/3060"}
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 2022-12-02T12:27:33.817Z    INFO    tls     closing
connection      {"remote-addr": "10.254.20.144:55042", "uri": "/portal-active-db-0/3060"}
[ ws-tunnel stderr]   400 0eec87:fb8309:21aa2d 2022-12-02 12:27:33: 10.254.20.144 - - [02/Dec/2022:12:27:33 +0000] "GET
/portal-active-db-0/3060 HTTP/1.1" 101 0
```

Note: It is normal for the management tunnel pod to repeatedly log:

```
2022/12/02 12:29:17 http: TLS handshake error from 10.254.16.1:44812: EOF
```

This message can be filtered out with **grep -v**:

```
kubectl logs management-tunnel-574bdcd865-48zh6 -n <namespace> | grep -v "http: TLS handshake error from"
```

Renewing TLS certificates

Renew TLS certificates in your API Connect deployment.

A default API Connect deployment uses cert-manager to create *issuers*, *CA certificates*, *server certificates*, and *client certificates*. Cert-manager monitors all the certificates that it creates, and renews them before they expire.
Note: If you are not using cert-manager, or if you customized some or all or your API Connect certificates, then you are responsible for monitoring and renewing those certificates.
Certain API Connect configuration and maintenance operations can require that some or all TLS certificates that are used by API Connect are renewed before their expiry. The process of updating API Connect TLS certificates is called "certificate renewal". The process to renew certificates involves the following steps:

1. Manually deleting Kubernetes secrets that contain the TLS certificates that need renewal.
2. Cert-manager detecting the deletion of these secrets, and automatically creating new secrets that contain newly generated x509 certificates.

Steps steps for identifying and renewing API Connect certificates are described in the following topics:

- **Renewing cert-manager controlled certificates**
  Use cert-manager to renew the issuers, CA certificates, and derived certificates that it manages for your API Connect deployment.
- **Renewing custom certificates**
  If you did not use cert-manager to generate certificates for your API Connect deployment, you must renew them manually.

- **List of Issuers, CA certificates, and secrets**
  A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment.
- **List of ingress certificates**
  A summary of certificates that are used for communications between subsystems and clients in an API Connect deployment.
- **List of intra-subsystem certificates**
  A summary of certificates used for communications within subsystems in an API Connect deployment.
- **V2018 upgrade: List of certificates to update manually**
  If you upgraded to API Connect V10 from V2018, some external certificates are carried over from the V2018 deployment and are not managed by cert-manager. When you update any of the retained certificates, you must restart the affected pods manually.
- **Renewing certificates in a two data center deployment on Kubernetes and OpenShift**
  Renewing TLS certificates in an API Connect two data center disaster recovery deployment requires you to copy some updated information between data centers while ensuring that the shared information is not overwritten during the remaining updates.

Related information

- API Connect TLS certificates reference page.

Renewing cert-manager controlled certificates

Use cert-manager to renew the issuers, CA certificates, and derived certificates that it manages for your API Connect deployment.

Cert-manager monitors and automatically renews all API Connect certificates before they expire. However, some API Connect maintenance operations require the manual renewal of certificates. The topics in this section describe how to manually trigger cert-manager to renew the certificates that it manages.

Key points to understand:

- If you replaced any cert-manager certificates with custom certificates, you must update these certificates manually before they expire. Cert-manager does not monitor custom certificates.
- Some API Connect pods must be restarted when certain API Connect certificates are renewed. See Pods that require restart after certificate renewal.
- When you renew a CA certificate, you must renew all the end-entity certificates that the CA signs. See API Connect TLS certificates reference.

Note: If your API Connect deployment was originally installed at v10.0.1.2 or earlier, then the certificate might be missing the `duration` and `renewBefore` properties. Before you renew any API Connect connect certificates, verify that your certificates have these properties, and if not then add them:

1. Run the following command to list of all the certificate names, with their `duration` and `renewBefore` properties:

   ```
   kubectl -n <namespace> get certificate -o custom-
   columns=NAME:metadata.name,DURATION:spec.duration,RENEWBEFORE:spec.renewBefore
   ```

   Example output where `management-ca` is missing the `duration` and `renewBefore` properties:

   ```
   NAME                                    DURATION     RENEWBEFORE
   analytics-ai-endpoint                   17520h0m0s   720h0m0s
   ...
   management-ca                           <none>       <none>
   ```

2. For each certificate output from step 1 that shows `<none>` for `duration` and `renewBefore`, edit the certificate and add these properties:

   ```
   kubectl -n <namespace> edit certificate <certificate name>
   ```

   Add the `duration` and `renewBefore` properties under the `spec` property as shown in the following example:

   ```
   ...
   spec:
   ...
     duration: <duration>
     renewBefore: 720h # 30 days
   ...
   ```

   where *<duration>* is:
   - `87600h` for CA certificates.
   - `17520h` for all other certificates.

- **Renewing the management-ca with the ManagementSecretRotation CR**
  Use the `ManagementSecretRotation` CR to renew the `management-ca` certificate and all end-entity certificates that `management-ca` signs.
- **Renewing the portal-ca with the PortalSecretRotation CR**
  Use the `PortalSecretRotation` CR to renew the `portal-ca` and all end-entity certificates that the `portal-ca` certificate signs.
- **Renewing the analytics CA**
  Renew the analytics CA certificate, and all end-entity certificates that the analytics CA signs.
- **Renewing the ingress-ca**
  Renew the ingress CA certificate, and all the end-entity certificates that the ingress CA signs.
- **Renewing end-entity certificates**
  Renew an API Connect end-entity certificate.
- **Monitoring cert-manager certificate renewal**
  How to monitor when your certificates are nearing their expiry, confirm that cert-manager is renewing them, and verify that dependent certificates are also renewed and related pods are restarted.

Renewing the `management-ca` with the ManagementSecretRotation CR

Use the **ManagementSecretRotation** CR to renew the **management-ca** certificate and all end-entity certificates that **management-ca** signs.

About this task

Applying the **ManagementSecretRotation** CR (Custom Resource) is the recommended method for renewing the **management-ca** and all its end-entity certificates. The alternative method is to manually renew the **management-ca** certificate and then each of its end-entity certificates, which you can identify from the certificates table Management certificates.

Restriction: The **ManagementSecretRotation** CR is for use with a single data center deployment. Do not attempt to use it with a two data center disaster recovery deployment. See Renewing certificates in a two data center deployment on Kubernetes and OpenShift.

Procedure

1. Create a file called management_cert_rotate.yaml and paste in the following contents:

```
apiVersion: management.apiconnect.ibm.com/v1beta1
kind: ManagementSecretRotation
metadata:
  name: mgmt-rotate-issuer
spec:
  managementCluster: <management CR name>
  rotateCertificates:
    certificates:
    - <management CR name>-ca
```

   where *<management CR name>* is the name of your **ManagementCluster** CR. You can identify this name with:

```
kubectl get ManagementCluster -n <management namespace>
```

2. Apply the CR by running the following command:

```
kubectl create -f management_cert_rotate.yaml -n <management namespace>
```

   Applying the CR updates the **management-ca**, and all end-entity certificates that **management-ca** signs. To view a list of the renewed certificates, run the following command:

```
kubectl describe ManagementSecretRotation mgmt-rotate-issuer -n <management namespace>
```

   The **status** block in the command output shows the renewed certificates:

```
Status:
...
  Phase:                  Completed
  Rotated Certs:
    def-management-ca
    def-management-client
    def-management-db-client-postgres
    def-management-natscluster-mgmt
    def-management-site1-postgres
    def-management-db-client-apicuser
    def-management-server
  State:  1/1
...
```

3. When certificate rotation is successfully completed, delete the **ManagementSecretRotation** CR.
   Confirm that certificate rotation is finished with the command:

```
kubectl get ManagementSecretRotation mgmt-rotate-issuer -n <management namespace>
```

   The output should show **Completed**:

```
NAME                 READY   STATUS      AGE
mgmt-rotate-issuer   1/1     Completed   6m52s
```

   Then delete the CR:

```
kubectl delete ManagementSecretRotation mgmt-rotate-issuer -n <management namespace>
```

Renewing the portal-ca with the PortalSecretRotation CR

Use the **PortalSecretRotation** CR to renew the **portal-ca** and all end-entity certificates that the **portal-ca** certificate signs.

About this task

Applying the **PortalSecretRotation** CR (Custom Resource) is the recommended method for renewing the **portal-ca** certificate and all its end-entity certificates. The alternative method is to manually renew the **portal-ca** certificate and then each of its end-entity certificates, which you can identify from the certificates table Portal certificates.

Restriction: The **PortalSecretRotation** CR is for use with a single data center deployment. Do not attempt to use it with a two data center disaster recovery deployment. See Renewing certificates in a two data center deployment on Kubernetes and OpenShift.

Procedure

1. Create a file called portal-secret-cr.yaml and paste in the following contents:

```
apiVersion: portal.apiconnect.ibm.com/v1beta1
kind: PortalSecretRotation
metadata:
  name: portal-rotate-secret
spec:
  portalCluster: <portal CR name>
  # List of certificates you want to rotate (Listing an issuer will rotate any certs issued by the issuer e.g listing just
portal-ca will rotate portal-ca, portal-client and portal-server)
  rotateCertificates:
    certificates:
    - <portal CR name>-ca
  rotateEncryptionSecret:
    # Set to true if you want to rotate the encryption secret.
    rotate: true
    # Optional value to set the encryption secret to, if supplied secret exists in the env. If not supplied the rotated
secret will be random.
    encryptionSecret: new-encyption-secret
```

   where *<portal CR name>* is the name of your **PortalCluster** CR. You can identify this name with:

```
kubectl get PortalCluster -n <portal namespace>
```

   If you set **rotate: true** in the **rotateEncryptionSecret** section, the portal-encryption-secret is updated and the following changes are made:
   - Change the root MySQL password.
   - Generate a new, site-specific MySQL password for each site.
   - Reencrypt all client_ids and client_secrets in the portal database.
2. Apply the CR by running the following command:

```
kubectl create -f portal-secret-cr.yaml -n <portal namespace>
```

   Applying the CR updates the **<portal CR name>-ca**, along with all end-entity certificates that it signs. To view a list of the updated certificates, run the following command:

```
kubectl describe PortalSecretRotation portal-rotate-secret -n <portal namespace>
```

   The **status** block in the command output shows the renewed certificates:

```
Status:
  ...
  Phase:                    Completed
  Rotated Certs:
    def-portal-ca
    def-portal-server
    def-portal-client
  State:  Completed Portal Secret Rotation.
...
```

3. When the certificate rotation is finished, delete the **PortalSecretRotation** CR.
   Confirm that certificate rotation is finished with the command:

```
kubectl get PortalSecretRotation portal-rotate-issuer -n <portal namespace>
```

   The output should show **Completed**:

```
NAME                   STATUS      MESSAGE                              AGE
portal-rotate-secret   Completed   Completed Portal Secret Rotation.    7m50s
```

   Then delete the CR:

```
kubectl delete PortalSecretRotation portal-rotate-issuer -n <portal namespace>
```

Renewing the analytics CA

Renew the analytics CA certificate, and all end-entity certificates that the analytics CA signs.

About this task

The pods that comprise the analytics subsystem communicate with each other using certificates that are signed by the analytics CA certificate. If you renew the analytics CA certificate, you must also renew the analytics end-entity certificates that the analytics CA signs.

For more information about API Connect certificates, see API Connect TLS certificates.

Procedure

1. Run the following command to renew the analytics CA certificate:

```
kubectl -n <analytics namespace> get certificate <analytics CA name> -o=jsonpath='{.spec.secretName}' | xargs kubectl -n
<analytics namespace> delete secret
```

   where *<analytics CA name>* is the name of the analytics CA certificate. On Kubernetes and OpenShift individual subsystem installations this name is **analytics-ca**. On Cloud Pak for Integration and OpenShift top-level CR installations, this name is **<apic instance name>-a7s-ca**.
   Verify that a new *<analytics CA name>* **secret** is created:

```
kubectl -n <analytics namespace> get secret
```

Output should show a new *<analytics CA name>* secret:

```
NAME                                                              TYPE                DATA   AGE
...
<analytics CA name>                                               kubernetes.io/tls   4      28s
```

Check that the **AGE** column shows the secret was recently created.

2. Renew the end-entity certificates signed by the analytics CA. Run the following command for each certificate:

```
kubectl get certificate <analytics certificate> -o=jsonpath='{.spec.secretName}' | xargs kubectl delete secret
```

where *<analytics certificate>* is the name of the end entity certificate. The analytics end-entity certificates are:

- **analytics-client** or **a7s-client**.
- **analytics-server** or **a7s-server**.

On Cloud Pak for Integration and OpenShift top-level CR installations, the certificate name is prefixed with ***<apic instance name>-***.

3. Verify that the **storage** and **warehouse** pods restarted, and manually restart the analytics **ingestion** and **director** pods so that they use the renewed certificates.

```
kubectl get pods
```

Check that **storage** and **warehouse** pods restarted:

```
NAME                                                READY   STATUS              RESTARTS         AGE
a7s-director-5b57848786-lg5w6                       1/1     Running             0                10d
a7s-ingestion-0                                     1/1     Running             0                6d16h
a7s-mtls-gw-5f5cb85744-gcwfw                        1/1     Running             0                37d
a7s-oscron-28600035-gnb2p                           0/1     Completed           0                19d
a7s-oscron-28600050-jgh4j                           1/1     Running             3 (19d ago)      19d
a7s-storage-0                                       0/1     ContainerCreating   1                5s
a7s-warehouse                                       0/1     ContainerCreating   1                5s
```

Note: Warehouse pods exist only when analytics backups are enabled.
Then delete the **ingestion** and **director** pods:

```
kubectl delete pod <analytics ingestion pod name>
```

```
kubectl delete pod <analytics director pod name>
```

Tip: For convenience, you can restart all analytics pods with a single command:

```
kubectl delete pod -l app.kubernetes.io/instance=<analytics CR name>
```

Renewing the ingress-ca

Renew the ingress CA certificate, and all the end-entity certificates that the ingress CA signs.

About this task

The ingress CA certificate signs all user-facing and inter-subsystem certificates. When you renew the ingress CA, you must renew all the end-entity certificates that the ingress CA signs.
For more information about API Connect certificates, see API Connect TLS certificates.

Procedure

1. Run the following command to renew the ingress CA certificate:

```
kubectl -n <management namespace> get certificate <ingress CA name> -o=jsonpath='{.spec.secretName}' | xargs kubectl -n <management namespace> delete secret
```

where *<ingress CA name>* is the name of the ingress CA certificate. On Kubernetes and OpenShift individual subsystem installations this name is **ingress-ca**. On Cloud Pak for Integration and OpenShift top-level CR installations, this name is ***<apic instance name>*-ingress-ca**.

2. Run the following command to renew all the end-entity certificates that the ingress CA signs:

```
kubectl get secrets -n <management namespace> -o custom-columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager\.io/issuer-name' --no-headers=true | grep ingress-issuer | awk '{ print $1 }' | xargs kubectl delete secret -n <management namespace>
```

3. If you have other subsystems that are in different namespaces from the management subsystem, then follow the steps in Copying renewed ingress-ca to subsystems in different namespaces.
4. Verify analytics in the developer portal.
Due to a known issue, when the **ingress-ca** is renewed, it is possible that Analytics in the Developer Portal might stop working. If this happens, complete the following steps to ensure that certificate changes take effect:
   a. Log in to the Cloud Manager user interface.
   b. In the navigation list, click Topology.
   c. Edit the Analytics service.
   d. On the Analytics page, edit the Summary field to force a change; for example, by adding a space to the end of a sentence.
   e. Click Save.

Copying renewed ingress-ca to subsystems in different namespaces

When the ingress CA certificate on the management subsystem is renewed, you must copy the renewed certificate to any subsystems that are in a different namespace.

Before you begin

Complete the steps in Renewing the ingress-ca to renew the ingress CA in your management subsystem namespace.
Note: If all your API Connect subsystems are in the same namespace, you do not need to follow this procedure.

About this task

The ingress CA signs all the inter-subsystem communication certificates that are used between API Connect subsystems. If your subsystems are installed in different namespaces, then the ingress CA must be manually synchronized across all those namespaces.

These steps must be repeated for all namespaces where you have subsystems that are registered with your management subsystem.

For more information about API Connect certificates, see API Connect TLS certificates.

Procedure

1. Export the management namespace ingress CA secret to a YAML file called ingress-ca.yaml:

   ```
   kubectl -n <management namespace> get secret ingress-ca -o yaml > ingress-ca.yaml
   ```

2. Edit `ingress-ca.yaml` and remove all `metadata` fields except for the secret name. The resulting file contents look like this:

   ```
   apiVersion: v1
   data:
     ca.crt: ...
     tls.crt: ...
     tls.key ...
   kind: Secret
   metadata:
     name: ingress-ca
   type: kubernetes.io/tls
   ```

3. Apply the updated the `ingress-ca.yaml` in the namespace of the other subsystem:

   ```
   kubectl -n <other subsystem namespace> apply -f ingress-ca.yaml
   ```

4. Verify that the ingress CA is now identical in both namespaces.
   a. Extract your `ingress-ca` secret to a file in your management namespace:

      ```
      kubectl -n <management namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print $2}'
      | base64 -d > ingress.pem.mgmt
      ```

   b. Extract your `ingress-ca` secret to a file in your other subsystems' namespace:

      ```
      kubectl -n <other subsystem namespace> get secrets ingress-ca -o yaml | grep tls.crt | grep -v 'f:tls' | awk '{print
      $2}' | base64 -d > ingress.pem.other
      ```

   c. Verify that the files that are created for each namespace are identical:

      ```
      diff ingress.pem.mgmt ingress.pem.mgmt
      ```

5. Run the following command to renew all the `ingress-ca` end-entity certificates in the other subsystems' namespace:

   ```
   kubectl get secrets -n <other subsystem namespace> -o custom-
   columns='NAME:.metadata.name,ISSUER:.metadata.annotations.cert-manager\.io/issuer-name' --no-headers=true | grep ingress-
   issuer | awk '{ print $1 }' | xargs kubectl delete secret -n <other subsystem namespace>
   ```

Renewing end-entity certificates

Renew an API Connect end-entity certificate.

About this task

To renew an end-entity certificate, delete the secret that corresponds to the certificate. Cert-manager detects the deletion of the secret and re-creates it with a new x509 certificate.

For more information about API Connect certificates, see API Connect TLS certificates.

Procedure

1. Get a list of all certificates in your API Connect namespace:

   ```
   kubectl -n <namespace> get certificates
   ```

The output lists all certificates with their status, age, and the name of the corresponding secret. In this example, the certificate that is used by the API Manager UI is shown:

```
NAME                                    READY   SECRET                                  AGE
...
apim-endpoint                           True    apim-endpoint                           13d
...
```

By default the secret names are identical to the certificate names.

2. Delete the secret for the certificate that you want to renew:

   ```
   kubectl -n <namespace> delete secret <secret name>
   ```

   Cert-manager detects the deletion of the secret and creates a new secret with a newly generated x509 certificate.

Monitoring cert-manager certificate renewal

How to monitor when your certificates are nearing their expiry, confirm that cert-manager is renewing them, and verify that dependent certificates are also renewed and related pods are restarted.

CA certificate renewal

If cert-manager renews a CA certificate, you must renew all the certificates that the CA signs. See API Connect TLS certificates reference.

Monitoring when your certificates are due to expire

Check when your certificates are due to expire with the following command:

```
kubectl -n <namespace> get certificate -o custom-
columns=NAME:metadata.name,DURATION:spec.duration,RenewBEFORE:spec.renewBefore,NotAFTER:status.notAfter
```

Example output:

```
NAME                                    DURATION     RenewBEFORE   NotAFTER
analytics-ingestion-client              17520h0m0s   720h0m0s      2025-08-28T08:25:58Z
api-endpoint                            17520h0m0s   720h0m0s      2025-08-28T08:28:40Z
apim-endpoint                           17520h0m0s   720h0m0s      2025-08-28T08:28:21Z
```

The example output shows that your `analytics-ingestion-client` is due to expire at `2025-08-28T08:25:58Z`. The `RenewBEFORE` property shows that cert-manager should renew this certificate 720 hours before it expires.

Monitoring the cert-manager manager logs

Monitor the cert-manager logs to confirm when certificates are renewed. Run the following command to display the cert-manager log:

```
kubectl logs <cert-manager pod name> -n <cert-manager namespace>
```

Example output:

```
I0108 14:23:18.001074       1 controller.go:129] cert-manager/controller/certificates "level"=0 "msg"="syncing item"
"key"="default/test-cert"
I0108 14:23:18.009940       1 issue.go:109] cert-manager/controller/certificates/certificates/issue "level"=0
"msg"="certificate issued" "related_resource_kind"="Secret" "related_resource_name"="test-cert"
"related_resource_namespace"="default"
I0108 14:23:18.018664       1 sync.go:331] cert-manager/controller/certificates/certificates "level"=0 "msg"="certificate
scheduled for renewal" "duration_until_renewal"="-5.018566857s" "related_resource_kind"="Secret" "related_resource_name"="test-
cert" "related_resource_namespace"="default"
I0108 14:23:18.019070       1 controller.go:135] cert-manager/controller/certificates "level"=0 "msg"="finished processing work
item" "key"="default/test-cert"
```

The 4 statements (shown in the example) indicate when a certificate is about to be renewed, and when the renewal is complete a few seconds later.
Tip: Set up a logs-based alerting mechanism that informs you when cert-manager renews any certificate.

Pods that require restart after certificate renewal

Some API Connect pods must be restarted when certificates that are used by the pod are renewed. The certificates that require pods to be restarted after renewal are:

- `analytics-ingestion-client` or `a7s-ing-client`. Restart `apim`, `taskmanager`, and `analytics-proxy` pods on the management subsystem.
- `gateway-client-client` or `gw-dr-client`. Restart the `apim` and `taskmanager` pods on the management subsystem.
- `analytics-ai-endpoint` or `a7s-ai-endpoint`. Restart the `mtls-gw` pod on the analytics subsystem.

Renewing custom certificates

If you did not use cert-manager to generate certificates for your API Connect deployment, you must renew them manually.

Procedure

1. Renew the certificates that you created:
   Use one of the following methods to renew the certificates that you created:
   - Update the secret that contains the certificate with your new certificate.
   - Delete and then re-create the secret with a new certificate.
   - Create a new secret (with a new name) that contains your new certificate. Update the appropriate API Connect CR to reference the new secret name.
2. Some pods require a restart after you update certain certificates. Refer to API Connect certificate reference to check whether any of the certificates you updated require pod restarts.

List of Issuers, CA certificates, and secrets

A summary of certificate issuers, with the CA issued by each, and the corresponding secret used to sign certificates in an API Connect deployment.

Table 1 presents a list of the certificate issuers used in an API Connect deployment, with the CA issued by each, and the corresponding secret used to sign certificates. The **selfsigning-issuer** is used only for creating CAs, and does not have a corresponding certificate or secret of its own. If you have customized certificates, the certificates generated by the issuers in Table 1 use the custom-certs-external.yaml template.

Table 1. Issuers, CAs, and secrets

Issuer	CA certificate	Secret
selfsigning-issuer	N/A	N/A
ingress-issuer	**ingress-ca** issued by **selfsigning-issuer**	**ingress-ca** Attention: If you change the **ingress-ca** secret in a two data center deployment, you must change it to the same value in both data centers.
analytics-ca	**analytics-ca** issued by **selfsigning-issuer**	**analytics-ca**
management-ca	**management-ca** issued by **selfsigning-issuer**	**management-ca**
portal-ca	**portal-ca** issued by **selfsigning-issuer**	**portal-ca**

Note: On Cloud Pak for Integration, and OpenShift top-level CR deployments, some certificate names are contracted and prefixed with the **APIConnectCluster** instance name. For example, the certificate **managment-ca** is called ***<apic instance name>*-mgmt-ca**.

List of ingress certificates

A summary of certificates that are used for communications between subsystems and clients in an API Connect deployment.

Note: On Cloud Pak for Integration, and OpenShift top-level CR deployments, some certificate names are contracted and prefixed with the **APIConnectCluster** instance name. For example, the certificate **managment-ca** is called ***<apic instance name>*-mgmt-ca**.

User-facing certificates

Table 1 presents a list of user-facing certificates. The corresponding secrets use the same names. If you customized your certificates, the certificates in Table 1 use the custom-certs-external.yaml template.

Table 1. User-facing certificates

Certificate name	Issuer	Description
api-endpoint or mgmt-platform-api	**ingress-issuer**	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
consumer-endpoint or mgmt-consumer-api	**ingress-issuer**	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
consumer-catalog	**ingress-issuer**	Consumer catalog endpoint server certificate.
apim-endpoint or mgmt-api-manager	**ingress-issuer**	API Manager UI server certificate.
cm-endpoint or mgmt-admin	**ingress-issuer**	Cloud Manager UI server certificate.
portal-web	**ingress-issuer**	The server certificate used on the **portalUIEndpoint**. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default **portal-web** certificate is issued by the **ingress-issuer**, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate. This certificate is used by the **portal-web** ingress (**portal-web** route on OpenShift).
hub-endpoint	**ingress-issuer**	Used by the Automated API behavior testing application. User-facing server certificate for the **hub-endpoint**. If there is a problem with this certificate, then the user's browser shows a warning or error message.

Inter-subsystem certificates

Table 2 lists all of the common subsystem communication certificates. The corresponding secrets use the same names. If you have customized your certificates, the certificates in Table 2 use the custom-certs-external.yaml template.

Table 2. Inter-subsystem certificates

Certificate name	Issuer	Description
`-ingress-ca`	`selfsigning-issuer`	The CA and issuer of all API Connect inter-subsystem and user-facing certificates. If there is a problem with this certificate, then all API Connect subsystems are inaccessible and unable to sync with each other. Update this certificate with **kubectl**. When updated, all child certificates must also be updated by deleting their corresponding secrets. See ingress-ca renewal. The ingress-ca certificate is also stored in the management subsystem database. It is visible from the Cloud Manager UI, in the truststores of the analytics, gateway, event gateway, and portal default TLS client profiles. When the management subsystem `apim` pod is restarted the certificate is reloaded into the database from the Kubernetes ingress-ca certificate. Do not attempt to update this certificate from the Cloud Manager UI. In 2DCDR deployments, and when you have subsystems in different namespaces, it is necessary to manually copy the ingress-ca certificate from the management subsystem to the other subsystems. Steps are provided in the 2DCDR and multi-namespace install sections of this documentation. If this certificate is updated, and you have a portal deployed, then restart the `portal-www` pods for the update to take effect.

`analytics-ingestion-client or a7s-ing-client`	`ingress-issuer`	Client certificate used for communication with the analytics subsystem on the ingestion endpoint. This certificate must have:
		• The same CA as the server certificate `analytics-ai-endpoint` on the analytics subsystem.
		• The common name must match the `spec.clientSubjectDN` in the analytics CR:
		`kubectl describe cert analytics-admin-client`
		`Spec:`
		`  Common Name:  a7s-ing-client`
		`kubectl get a7s -o yaml`
		`  spec:`
		`    clientSubjectDN: CN=a7s-ing-client`
		
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=a7s-ingestion-client`, or they could both be `CN=a7s-ingestion-client, O=cert-manager`, but they must be identical.
		
		To update this certificate, use kubectl. Restart the `apim`, `taskmanager`, and `analytics-proxy` pods after the update. This certificate is also used by the gateways for sending API events to the analytics subsystem. The updated certificate is sent by the management subsystem to the gateways, it is not necessary to restart any gateway pods.
		
		This certificate is loaded by the management subsystem into the `Analytics ingestion TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the analytics subsystem, then create a new profile and specify it when you register the analytics service.

`portal-admin-client or ptl-adm-client`	`ingress-issuer`	Client certificate used for communication with the portal subsystem on the `portalAdminEndpoint`. This certificate must have:
		• The same CA as the server certificate `portal-admin or ptl-director` on the portal subsystem.
		• The common name must match the `spec.adminClientSubjectDN` in the portal CR:
		`kubectl describe cert portal-admin-client`
		`Spec:`
		`  Common Name:  ptl-adm-client`
		`kubectl get ptl -o yaml`
		`  spec:`
		`    adminClientSubjectDN: CN=ptl-adm-client`
		
		For a two data center disaster recovery deployment, both data centers must have an identical subject name. For example, both data centers subject name could be `CN=portal-admin-client`, or they could both be `CN=ptl-adm-client, O=cert-manager`, but they must be identical.
		
		This certificate is loaded by the management subsystem into the `Portal Director TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the portal, then create a new profile and specify it when you register the portal service.

`gateway-client-client or gw-dr-client`	`ingress-issuer`	Client certificate for communications with the gateway service. Restart the `apim` and `taskmanager` pods after update. This certificate must have the same CA as the `gwv6-manager-endpoint or gw-gateway-manager` certificate on the gateway. This certificate is loaded by the management subsystem into the `Gateway management client TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the gateway, then create a new profile and specify it when you register the gateway service.
`api-endpoint or mgmt-platform-api`	`ingress-issuer`	Platform API endpoint server certificate. The certificate that is presented to callers of the platform REST API, and to the toolkit CLI.
`consumer-endpoint or mgmt-consumer-api`	`ingress-issuer`	Consumer API endpoint server certificate. The certificate presented that is presented to callers of the consumer REST API, and to the toolkit CLI.
`apim-endpoint or mgmt-api-manager`	`ingress-issuer`	API Manager UI server certificate.

Certificate name	Issuer	Description
`cm-endpoint or mgmt-admin`	`ingress-issuer`	Cloud Manager UI server certificate.
`mgmt-replication-client`	`ingress-issuer`	2DCDR deployments only. Client certificate used in the warm-standby data center's `<remote-sitename>-postgres` pod to connect to the active data center.
`mgmt-replication-server`	`ingress-issuer`	2DCDR deployments only. Server certificate used in the active data center's `<management_CR>-tunnel` pod. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the `spec.multiSiteHA.replicationEndpoint` defined in the management CR.
`hub-endpoint`	`ingress-issuer`	Used by the Automated API behavior testing application. User-facing server certificate for the `hub-endpoint`. If there is a problem with this certificate, then the user's browser shows a warning or error message.
`management-s3proxy-all`	`ingress-issuer`	Inter-subsystem certificate for communication between management subsystem and s3proxy pods. Used for management database local and SFTP backups.
`analytics-ai-endpoint or a7s-ai-endpoint`	`ingress-issuer`	Server certificate used on the analytics ingestion endpoint, in the `mtls-gw` pod. Management and gateway subsystems communicate with the analytics subsystem on this endpoint. The client certificates that are used by the management and gateway subsystems must use the same CA certificate as the `analytics-ai-endpoint` certificate. If this certificate is updated, restart the `mtls-gw` pod for the update to take effect.
`portal-admin or ptl-director or portal-director`	`ingress-issuer`	Server certificate used on the `portalAdminEndpoint`. The management subsystem communicates with the portal subsystem on this endpoint. The corresponding client certificate used in the management to portal communication is the `portal-admin-client` certificate. This certificate must have the same CA as the `portal-admin-client` certificate on the management subsystem. This certificate is used by the `portal-nginx` pod.
`portal-web`	`ingress-issuer`	The server certificate used on the `portalUIEndpoint`. It is the server certificate that is presented to portal site users, and which their browser authenticates. If there is a problem with this certificate, then users see an error message about an invalid or insecure certificate in their browser when they access a portal site. The default `portal-web` certificate is issued by the `ingress-issuer`, which has a self-signed root certificate. Portal users might see a browser warning about use of a self-signed certificate. This certificate is used by the `portal-web` ingress (`portal-web` route on OpenShift).
`ptl-replication-client`	`ingress-issuer`	2DCDR deployments only. Client certificate that is used in the warm-standby data center's `<remote-sitename>-www` and `<remote-sitename>-db` pods to connect to the active data center. This certificate is used by all the portal pods related to 2DCDR replication: `portal-db-remote`, `portal-www-remote`, and `portal-tunnel`.
`ptl-replication-server`	`ingress-issuer`	2DCDR deployments only. Server certificate used in the active data center's `<portal_CR>-tunnel` pod, the counterpart to the `ptl-replication-client` certificate. This certificate must contain the DNS Subject Alternative Name of this data center's hostname and must be valid for the `spec.multiSiteHA.replicationEndpoint` defined in the portal CR. This certificate is used by all the portal pods related to 2DCDR replication: `portal-db-remote`, `portal-www-remote`, and `portal-tunnel`.
`gateway-peering or gw-peer`	`ingress-issuer`	This certificate secures the communication between gateways in your gateway cluster. If you update this certificate, then restart your gateway pods. See Changing the secret for gateway peering.
`gwv6-endpoint or gw-gateway`	`ingress-issuer`	Legacy certificate that is not used.
`gateway-service or gw-svc`	`ingress-issuer`	Legacy certificate that is not used.
`gwv6-manager-endpoint or gw-gateway-manager`	`ingress-issuer`	The `gatewayManager` endpoint certificate. This is the server certificate on the gateway director endpoint, which the management subsystem communicates with. This certificate must be signed by the same CA as the `gateway-client-client` certificate on management subsystem If you update this certificate, then all gateway pods are restarted automatically.
`event-gateway-management-client`	`ingress-issuer`	The `event-gateway-management-client` certificate exists only on Cloud Pak for Integration deployments.

List of intra-subsystem certificates

A summary of certificates used for communications within subsystems in an API Connect deployment.

Note: On Cloud Pak for Integration, and OpenShift top-level CR deployments, some certificate names are contracted and prefixed with the `APIConnectCluster` instance name. For example, the certificate `managment-ca` is called `<apic instance name>-mgmt-ca`.
Table 1 presents a list of certificates used for communications between pods in the same subsystem. The certificates are managed by cert-manager. For details of all the API Connect certificates, see API Connect certificates.

Table 1. Intra-subsystem certificates

Certificate name	Issuer	Description

Certificate name	Issuer	Description
`management-ca or mgmt-ca`	`selfsigning-issuer`	The issuer for the management subsystems intra-subsystem certificates: management-client, management-server, postgres, and nats certificates. Communication between management subsystem pods fails if there is a problem with this certificate. This certificate is also used as the CA for REST API calls to the management subsystem from the other subsystems, when using `in-cluster` communication. See In-cluster service communication between subsystems
`management-client or mgmt-client`	`management-ca`	Client certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.

`management-server or mgmt-server`	`management-ca`	Server certificate used in communication between management subsystem pods. Communication between management subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`

`db-client-apicuser`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`db-client-postgres`	`management-ca`	Intra-subsystem certificate for the management database subsystem.
`natscluster-mgmt`	`management-ca`	Intra-subsystem certificate for the `nats` pods.
`analytics-ca or a7s-ca`	`selfsigning-issuer`	The issuer for the `analytics-client` and `analytics-server` certificates. Communication between analytics subsystem pods fails if there is a problem with this certificate. If you update this certificate, you must then update the `analytics-client` and `analytics-server` server certificates, and then ensure that the following pods are restarted: • `storage`: Restarts automatically. • `warehouse`: Restarts automatically. • `ingestion`: Restarts automatically. • `director`: Restart manually.
`analytics-client or a7s-client`	`analytics-ca`	Client certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate. If this certificate is updated, then the `storage`, `warehouse` and `ingestion` pods restart automatically. You must manually restart the `director` pod.

`analytics-server or a7s-server`	`analytics-ca`	Server certificate used in communication between analytics subsystem pods. Communication between analytics subsystem pods fails if there is a problem with this certificate.
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`
		`<instance name>-storage`
		`<instance name>-director`
		`<instance name>-ingestion`
		`<instance name>-mtls-gw`
		`<instance name>-storage-os-master`
		`<instance name>-warehouse`
		
		If this certificate is updated, then the `storage`, `warehouse` and `ingestion` pods restart automatically. You must manually restart the `director` pod.

`portal-ca or ptl-ca`	`selfsigning-issuer`	The issuer for the portal-client and portal-server certificates. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.
`portal-client or ptl-client`	`portal-ca`	Client certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate. This certificate is used by all portal pods.

`portal-server or ptl-server`	`portal-ca`	Server certificate used in communication between portal subsystem pods. Communication between portal subsystem pods fails if there is a problem with this certificate.
		
		Required DNS names within the SAN section are:
		
		`*.<namespace>`
		`*.<namespace>.svc`
		`*.<namespace>.svc.cluster.local`
		`*.<instance name>-server.<namespace>.svc`
		`*.<instance name>-server.<namespace>.svc.cluster.local`
		`<instance name>-server`
		`*.<instance name>-<site name>-db-all.<namespace>.svc`
		`*.<instance name>-<site name>-www-all.<namespace>.svc`
		`*.<instance name>-<site name>-db-all.<namespace>.svc.cluster.local`
		`*.<instance name>-<site name>-www-all.<namespace>.svc.cluster.local`
		`*.<namespace>.svc.cluster.local`
		`<instance name>-db`
		`#<remote portal CR name>-db # For 2DCDR only.`
		
		<instance name> and *<remote portal CR name>* are truncated if more than 15 characters.
		This certificate is used by all portal pods.

V2018 upgrade: List of certificates to update manually

If you upgraded to API Connect V10 from V2018, some external certificates are carried over from the V2018 deployment and are not managed by cert-manager. When you update any of the retained certificates, you must restart the affected pods manually.

Ingress (front-end) certificates

Table 1 presents a list of the ingress certificates that were carried forward when you upgraded from V2018, and the pods that you must restart when you update each certificate.

If multiple Portal web ingress endpoints have been configured, then the certificates for those additional endpoints must be updated manually as well.

Table 1. V2018 ingress certificates and affected pods

Certificate and Secret	Pods
`client-tls-xxxxxxxxxx`	• `analytics-mtls-gw-hashed-suffix`
`ingestion-tls-xxxxxxx`	• `analytics-mtls-gw-hashed-suffix`
`platform-api-tls-xxxxxxx`	N/A
`api-manager-tls-xxxxxxxx`	N/A
`cloud-manager-tls-xxxxxx`	N/A
`consumer-api-tls-xxxxxxx`	N/A
`v5GwName-datapower-admin-credentials`	N/A
`v5GwName-apic-gateway-peering-tls`	N/A
`v5GwName-apic-gateway-service-tls`	N/A
`v6GwName-datapower-admin-credentials`	N/A
`v6GwName-apic-gateway-peering-tls`	N/A
`v6GwName-apic-gateway-service-tls`	N/A
`portal-uuid-admin`	• `portal-nginx`
`www-tls-xxxxxxxxxxxxx`	N/A

Subsystem communication certificates

Table 2 presents a list of the subsystem communication certificates that were carried forward when you upgraded from V2018, and the pods that you must restart when you update each certificate.

Table 2. V2018 subsystem communication certificates and affected pods

Usage	Certificate and Secret	Pods
client	`managementUpgradeName-analytics-ingestion-client`	• `management-apim` • `management-taskmanager` • `gateway` (via webhook, no restart needed)
client	`managementUpgradeName-portal-admin`	• `management-apim` • `management-taskmanager` • `management-portal-proxy`
client	`gw-apic-gateway-service-tls`	• `gwv6` • `gwv5`
clientserver	`gw-apic-gateway-peering-tls`	• `gwv6` (redis) • `gwv5` (redis)

Database encryption key

The database encryption key is carried forward from V2018, and uses the name: `managementUpgradeName-encryption-secret`. You can update the value of this secret as explained in Changing the database encryption key.

Renewing certificates in a two data center deployment on Kubernetes and OpenShift

Renewing TLS certificates in an API Connect two data center disaster recovery deployment requires you to copy some updated information between data centers while ensuring that the shared information is not overwritten during the remaining updates.

About this task

Begin the process by updating certificates as needed on data center 1 (DC1). Then,copy the `ingress-ca` from DC1 to data center 2 (DC2) before updating certificates on DC2. Finally, you will copy encryption keys for the Management and Portal subsystem from DC1 to DC2.

Procedure

Complete the following steps in the sequence shown to ensure that you do not overwrite information that was copied from DC1 while updating DC2.

1. DC1: Renew TLS certificates as explained in Renewing TLS certificates.
2. DC2: Complete the following steps to copy the **ingress-ca** from DC1:
   a. On DC1, export the **ingress-ca** secret to a YAML file by running the following command:

      ```
      kubectl -n namespace get secret ingress-ca -o yaml > ingress-ca.yaml
      ```

   b. Still on DC1, edit the **ingress-ca.yaml** file to remove all labels, annotations, **creationTimestamp**, **resourceVersion**, **uid**, and **selfLink**.
   c. Copy the **ingress-ca.yaml** to DC2.
   d. On DC2, apply the **ingress-ca.yaml** file by running the following command:

      ```
      kubectl -n namespace apply -f ingress-ca.yaml
      ```

   e. Validate that the **ingress-ca** on DC2 matches the **ingress-ca** on DC1:
      i. On DC1, run the following command to save the original **ingress-ca** as a PEM file:

         ```
         kubectl -n namespace get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
         /tmp/ingress.pem.dc1
         ```

      ii. On DC2, run the following command to save the copied **ingress-ca** as a PEM file::

         ```
         kubectl -n namespace get secrets ingress-ca -o yaml | grep tls.crt | awk '{print $2}' | base64 -d >
         /tmp/ingress.pem.dc2
         ```

      iii. Copy /tmp/ingress.pem.dc1 from DC1 and store it in the /tmp folder on DC2.
      iv. On DC2, run the following command to compare the two files and verify that there are no differences:

         ```
         diff /tmp/ingress.pem.dc1 /tmp/ingress.pem.dc2
         ```

3. DC2: Update all external certificates that are based on the **ingress-ca** (see List of ingress certificates).
4. DC2: Update all of the internal certificates (see List of intra-subsystem certificates).
   At this point, DC1 and DC2 have the same **ingress-ca** secrets. Next, copy the encryption keys for the Management and Portal subsystems from DC1 to DC2.

5. Copy the encryption key for the Management subsystem to DC2 by completing the following steps:
   a. On DC1, copy the management encryption key:
      i. Get the name of the management encryption key by running the following command:

         ```
         $ kubectl -n namespace get mgmt -o yaml|grep enc
         ```

         The response looks like the following example:

         ```
         encryptionSecret: dallas-enc-key
         ```

         Make a note of the secret name for the next step. In the example, the key's name is **dallas-enc-key**.

      ii. Retrieve the secret from the encryption key by running the following command (substitute in the name of the key from the previous step):

         ```
         kubectl get secret dallas-enc-key -o yaml
         ```

         The output looks like the following example:

         ```
         apiVersion: v1
         data:
           encryption_secret.bin:
         VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
         pyLiY5g*****************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
         kind: Secret
         metadata:
           creationTimestamp: "2020-08-28T12:53:41Z"
           labels:
             app.kubernetes.io/instance: m1
             app.kubernetes.io/managed-by: ibm-apiconnect
             app.kubernetes.io/name: dallas-enc-key
           name: dallas-enc-key
           namespace: default
           resourceVersion: "43039"
           selfLink: /api/v1/namespaces/default/secrets/m1-enc-key
           uid: 46c92395-9cc2-4421-b2c4-48e472c0cbb1
         type: Opaque
         ```

      iii. Copy the output and save it in a YAML file; for example dc1-enc-key.yaml.
      iv. Edit the file and make the following changes:
         - Delete the contents of the **metadata:** section (retain the section).
         - In the **metadata:** section, add in a **name:** attribute, with **dc1-enc-key** as the value.

         The following example shows the updated file:

         ```
         apiVersion: v1
         data:
           encryption_secret.bin:
         VKBNFj7sAOizxvE1H6i+9P31oJHvWWsO+x**********************************EGe/K+x6b3D7FEWGgoyGlWBUJKB4+T21My2iR5rBTov
         pyLiY5g*****************************************tSiRcQKegMPNBPgL829SVBCxuv3I=
         kind: Secret
         metadata:
           name: dc1-enc-key
         type: Opaque
         ```

      v. Copy the updated file (dc1-enc-key.yaml) to the /tmp folder on DC2.
   b. On DC2, run the following command to create a secret from the encryption key file (dc1-enc-key.yaml) that you copied from DC1:

      ```
      $ kubectl  -n namespace create -f /tmp/dc1-enc-key.yaml
      ```

The response looks like the following example:

```
secret/dc1-enc-key created
```

6. Update the encryption key for the Portal subsystem on DC1 and then copy it to DC2 as explained in Changing the secret for portal data and system tools.

Monitoring and health checks

Monitor your deployment and complete health checks on subsystems.

See:

- **Monitoring on Kubernetes**
  Monitor the API Connect subsystems on Kubernetes.
- **Monitoring on OpenShift**
  Monitor your API Connect deployment on OpenShift.
- **Monitoring on Cloud Pak for Integration**
  Monitor your API Connect deployment on Cloud Pak for Integration.
- **Obtaining simple health check data of Developer Portal sites by using a REST API call**
  Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

Monitoring on Kubernetes

Monitor the API Connect subsystems on Kubernetes.

See:

- **Monitoring subsystems on Kubernetes**
  Use `kubectl get` to check the health of the API Connect clusters in your Kubernetes deployment.
- **Monitoring Postgres disk usage**
  Monitor disk usage by the Postgres database in the management subsystem.
- **Monitoring platform health using Kubernetes events**
  Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

Monitoring subsystems on Kubernetes

Use `kubectl get` to check the health of the API Connect clusters in your Kubernetes deployment.

The APIConnect operator controls the life-cycle of management subsystem microservices. When you install, you create the following custom resources (CRs) in order to install API Connect and all subsystems:

- `ManagementCluster` or `mgmt`
- `AnalyticsCluster` or `a7s`
- `PortalCluster` or `ptl`
- `GatewayCluster` or `gw`
  Every CR has a `status` section. The APIConnect operator regularly updates this section with the current status of the subsystem.

For example, use the following command to obtain the status of `ManagementCluster`:

```
kubectl get mgmt -n <namespace>
```

Example:

```
kubectl get mgmt
NAME    READY   STATUS    VERSION      RECONCILED VERSION      AGE
m1      16/16   Running   10.0.8.0      10.0.8.0-44   24m
```

Output:

- `NAME`: Name of the Management Subsystem
- `READY`: Current number of management subsystem which are up, followed by the expected number of management subsystem components which should be up. For example: `16/16`.
- `STATUS`: Current status of Management Subsystem
  During fresh install, upgrade or any maintenance operation, such as changing configuration for S3 backups, Management CR status can go to different states depending on the action, but ultimately it should **always** reach `Running` status.

  If the status says `Warning`, then run `kubectl describe mgmt -n <namespace>` and check for more details in the `Status` section.
- `VERSION`: Version chosen in `spec.version` in the management CR.
- `RECONCILED VERSION`: Current management subsystem version. Includes a build number.
- `AGE`: Age of the management subsystem CR.

Monitoring Postgres disk usage

Monitor disk usage by the Postgres database in the management subsystem.

Postgres Database is the core database used in Management Subsystem. It is important to monitor the Postgres disk usage.

The API Connect operator tracks the current disk usage of the Postgres components, and regularly updates the **`ManagementCluster`** status. When one or more of the Postgres components occupy 60% of the PVC (persistent volume claim) capacity, the API Connect operator changes the status from **`Running`** to **`Warning`**.

API Connect operator **brings down** Postgres if the disk allocation reaches **80%**. In this case, you must contact IBM support.

Note that there are various types of storage classes which can be used to deploy Management Subsystem. For example, **`local-storage`** or **`ceph block`**.

Management Cluster disk stats

The **`ManagementCluster`** instance has **`.status.postgresDataStats`** where the operator prints the current disk usage of Postgres components. For example:

```
kubectl get mgmt -o json | jq .status.postgresDataStats
[
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 51200,
    "pvcName": "",
    "pvcType": "WAL",
    "pvcUsed": 400,
    "pvcUsedPercentage": 8
  },
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 184320,
    "pvcName": "",
    "pvcType": "PostgreSQL",
    "pvcUsed": 95,
    "pvcUsedPercentage": 8
  }
]
```

Warning condition is populated at 60% usage

When one of the Postgres components occupy 60% usage, the operator marks the overall status of the **`ManagementCluster`** to **`Warning`** with an appropriate warning message. The operator also updates the **`postgresDataStats`** section with the current data usage of the Postgres components.

Example of warning state:

```
kubectl get mgmt
NAME              READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
AGE
stv3-management   6/8     Warning   10.0.8.0   10.0.8.0-5363        Some services are not ready - see status condition for
details   3d20h
```

Example of list of warning conditions:

```
kubectl get mgmt -o json
...
status:
  conditions:
  - lastTransitionTime: "2022-06-02T19:38:09Z"
    message: Warning threshold=60%, Current disk usage=63%, Is wal archiving working?=false.
      Database shutdown starts at 80%. Please contact IBM Support immediately.
    reason: wal_disk_usage_more_than_warning_threshold
    status: "True"
    type: Warning
...
```

If you encounter the warning, contact IBM support to fix the root cause.

Error condition is populated at 80% usage

An error condition is populated when the operator brings down Postgres because is using 80% of available disk space. Postgres is brought down to avoid problems, such as disk corruption, that can occur if the disk becomes completely filled.

```
 status:
  conditions:
- lastTransitionTime: "2022-06-03T00:40:54Z"
    message: Error threshold=80%, Current disk usage=82%, Is wal archiving working?=false.
      Database is in shutdown mode and management services are disabled. Please contact
      IBM Support immediately.
    reason: wal_disk_usage_more_than_error_threshold
    status: "True"
    type: Error
```

If you encounter the error, contact IBM support to fix the root cause.

Important:
When **`local-storage`** is used, it uses the entire disk that is allocated to the worker node. In some cases, Kubernetes itself can face disk pressure before the operator reacts to 80% usage, and will start evicting pods.

Monitoring platform health using Kubernetes events

Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

What are the Kubernetes events?

The CR for every subsystem of API Connect has a status condition section, which is regularly updated by the API Connect operator with the current status. The API Connect operator additionally generates a Kubernetes event whenever there is a change in the CR status.

Events are enabled in API Connect operator for the following resources.

- `APIConnectCluster` CR
- `ManagementCluster` CR
- `GatewayCluster` CR
- `AnalyticsCluster` CR
- `PortalCluster` CR

Two types of events are generated when the CR status changes:

- `Normal` - Indicates that the status change is not causing any issues.
- `Warning` - Indicates that there a problem that requires your attention.

You can automatically monitor the status condition in your existing alerting system, or by integrating the Kubernetes events into a third-party alerting solution. For more information, see the following blog post: How to use Kubernetes events for effective alerting and monitoring.

Viewing the events

The default retention period of events in Kubernetes is 1 hour (controlled by `kube-apiserver`). To view the events, complete the following steps:

1. Run the `kubectl describe` against the resource you want to monitor; for example:

   ```
   kubectl describe APIConnectCluster
   ```

2. In the response, scroll to the end to see the events information, which looks like the following example:

   ```
          Name:           10.0.5.3-1
      Reconciled:         10.0.5.3-1
   Events:
     Type     Reason     Age    From                       Message
     ----     ------     ----   ----                       -------
     Normal   Running    10h    ibm-apiconnect-operator    All services ready.
     Normal   Deploying  10h    ibm-apiconnect-operator    Not all services are ready, pending services: management
   ```

Monitoring on OpenShift

Monitor your API Connect deployment on OpenShift.

See:

- **Monitoring the API Connect cluster on OpenShift**
  Monitor the status of the API Connect cluster on OpenShift using either the command line or the OpenShift web console.
- **Monitoring Postgres disk usage on OpenShift**
  In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.
- **Monitoring platform health on Red Hat OpenShift using Kubernetes events**
  Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

Monitoring the API Connect cluster on OpenShift

Monitor the status of the API Connect cluster on OpenShift using either the command line or the OpenShift web console.

Note: For information on viewing the Postgres disk status, see Monitoring Postgres disk usage on OpenShift.

Monitoring the API Connect cluster using the command line

Individual subsystem installations: Run the `oc get` command on each subsystem CR:

- Management:

  ```
  oc get mgmt
  ```

  ```
  NAME              READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE               AGE
  small-ocp-mgmt    18/18   Running   10.0.8.0   10.0.8.0-258         Management is ready   53d
  ```

- Portal

  ```
  oc get ptl
  ```

```
NAME            READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE          AGE
small-ocp-ptl   4/4     Running   10.0.8.0   10.0.8.0-258         Serving 1 site   53d
```

- Analytics

  ```
  oc get a7s
  ```

  ```
  NAME            READY   STATUS    VERSION    RECONCILED VERSION   AGE
  small-ocp-a7s   7/7     Running   10.0.8.0   10.0.8.0-258         53d
  ```

- Gateway

  ```
  oc get gw
  ```

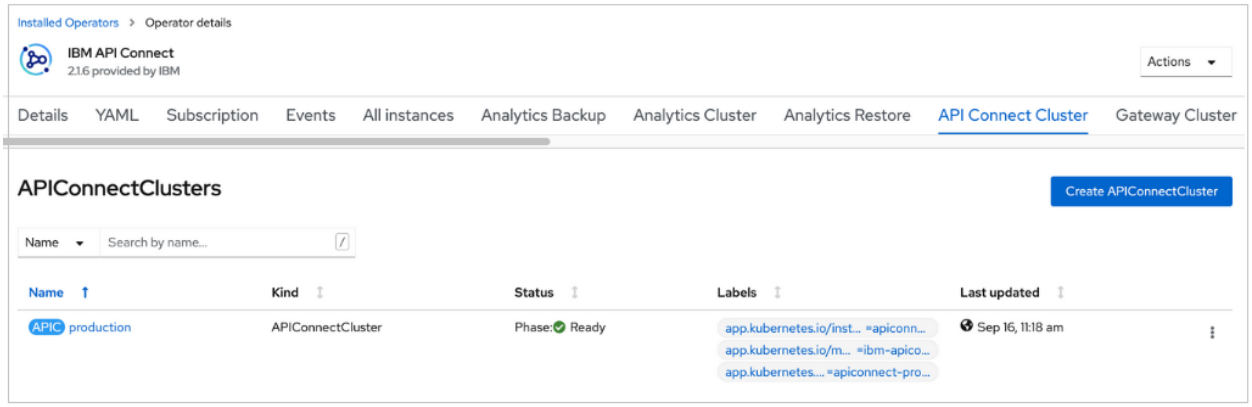
  ```
  NAME           READY   STATUS    VERSION    RECONCILED VERSION   AGE
  small-ocp-gw   2/2     Running   10.0.8.0   10.0.8.0-258         53d
  ```

Top-level CR installations: Run the following command to display the status of the API Connect cluster:

```
oc get apiconnectcluster -n <APIC_namespace>
```

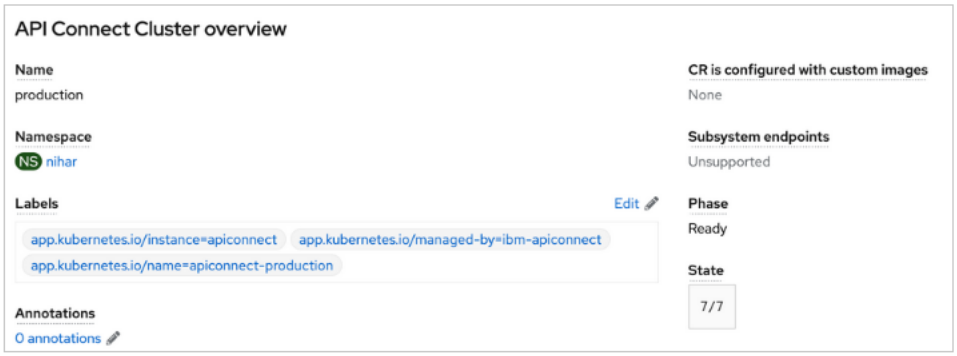
The response looks like the following example:

```
NAME         READY   STATUS   VERSION        RECONCILED VERSION   AGE
production   7/7     Ready    10.0.8.0   10.0.8.0-3323    24h
```



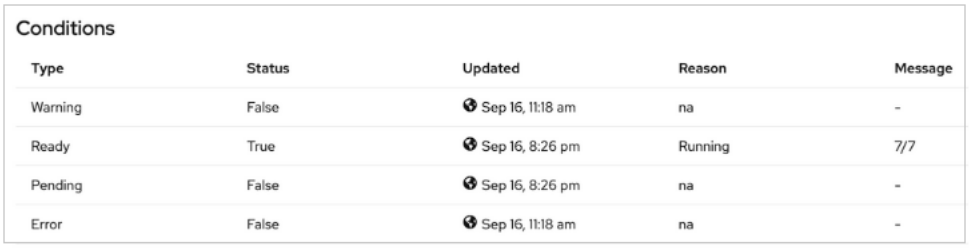
The following list explains the values in the response:

- **NAME**: Name of the API Connect cluster or subsystem instance.
- **READY**: Current number of components that are running **/** Expected number of components that should be running.
- **STATUS**: Current status of API Connect or the subsystem.
  If the status says **Warning**, then run **oc describe** ***<CR>*** and check for more details in the **Status** sections.



- **VERSION**: API Connect version specified in the CR's **spec.version** setting.
- **RECONCILED VERSION**: Current API Connect version.
- **AGE**: Age of the CR.

Monitoring the API Connect cluster using the OpenShift web console



1. Start the OpenShift web console.
2. Click Installed operators.
3. Locate the namespace (project) where you installed API Connect:
   - If you installed the API Connect operator in all namespaces, select openshift-operators
   - if you installed the API Connect operator in a single namespace, select specific project
4. Select the IBM API Connect operator.
5. Select All instances for an overview of all operands in your API Connect namespace.
6. If you have a top-level CR installation, then click API Connect Cluster.
   a. On the API Connect Clusters page, check the Status column.
   The status should display "Ready" as in the following image:

   b. Click the instance name (in the example, the instance name is production to display the status overview page.
   The overview page displays high-level information about your deployment, as in the following image:

Also on the overview page, the "Conditions" section displays the list of possible service conditions, as in the following image:

A healthy deployment displays "True" for the "Ready" status.

During a fresh install, an upgrade or a day-2 operation (such as a Management backup S3 configuration change), the **apiconnectcluster** CR status might change to a different state depending on the action, but ultimately it should always reach the **Ready** status.

Monitoring Postgres disk usage on OpenShift

In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.

The Postgres database is the core database used in the Management subsystem. It is important to monitor the Postgres disk usage to avoid running out of space and causing an outage in your deployment.

The **APIConnect** operator tracks the current disk usage of the Postgres components, and regularly updates the **ManagementCluster** CR's status. When one or more of the Postgres components occupy 60% of the PVC (persistent volume claim) capacity, the **APIConnect** operator changes the CR's status from **Running** to **Warning**.

Important: If the Postgres disk usage reaches 80%, then the **APIConnect** operator brings down Postgres. If this situation occurs, contact IBM Support.
Note that there are various types of storage classes which can be used to deploy Management subsystem; for example, **local-storage** or **ceph block**. When **local-storage** is used, the entire disk is allocated to the worker node. In some cases, before the **APIConnect** operator reacts to an 80% usage condition, Kubernetes itself might face disk pressure and start evicting pods.

Viewing the current disk usage

The **ManagementCluster** instance includes the **.status.postgresDataStats** field, where the operator displays the current disk usage of Postgres components. Run the following command to get the disk usage:

```
oc get mgmt -o json | jq .items[].status.postgresDataStats
```

The response looks like the following example:

```
[
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 51200,
    "pvcName": "",
    "pvcType": "WAL",
    "pvcUsed": 400,
    "pvcUsedPercentage": 8
  },
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 184320,
    "pvcName": "",
    "pvcType": "PostgreSQL",
    "pvcUsed": 95,
    "pvcUsedPercentage": 8
  }
]
```

Warning condition is populated at 60% usage

When one of the Postgres components uses 60% of its allocated space, the operator changes the overall status of the `ManagementCluster` to `Warning` with an appropriate warning message. The operator also updates the `postgresDataStats` section with the current data usage of the Postgres components.

Attention: If you encounter the `Warning` condition, contact IBM Support for help correcting the root cause.
To view the status, run the following command:

```
oc get mgmt
```

The following example response shows the warning state:

```
NAME              READY   STATUS    VERSION    RECONCILED VERSION   MESSAGE
AGE
stv3-management   6/8     Warning   10.0.8.0   10.0.8.0-5363        Some services are not ready - see status condition for
details   3d20h
```

To view just the status, run the following command:

```
oc get mgmt -o json | jq .items[].status.phase
```

In this example, the status displayed in the response is "Warning":

```
"Warning"
```

To see the list of current status conditions, run the following command:

```
oc get mgmt -o json | jq .items[].status.conditions
```

The following example response displays the list of status conditions. Notice that the `Warning`"condition is set to "True" and the other conditions are set to "False":

```
status:
  conditions:
  - lastTransitionTime: "2022-06-02T19:38:09Z"
    message: Warning threshold=60%, Current disk usage=63%, Is wal archiving working?=false.
      Database shutdown starts at 80%. Please contact IBM Support immediately.
    reason: wal_disk_usage_more_than_warning_threshold
    status: "True"
    type: Warning
```

Error condition is populated at 80% usage

When one of the Postgres components uses 80% of its allocated space, the operator changes the overall status of the `ManagementCluster` to `Error` and brings down Postgres avoid problems that can occur if the disk becomes completely filled.

Attention: If you encounter the `Error` condition, contact IBM Support for help correcting the root cause.
In this case, when you run the following command to view the status conditions, you will see that the "Error" condition is set to "True:

```
oc get mgmt -o json | jq .items[].status.conditions
```

For example, the following condition shows the `Error` status set to "True" due to disk usage:

```
status:
  conditions:
- lastTransitionTime: "2022-06-03T00:40:54Z"
    message: Error threshold=80%, Current disk usage=82%, Is wal archiving working?=false.
      Database is in shutdown mode and management services are disabled. Please contact
      IBM Support immediately.
    reason: wal_disk_usage_more_than_error_threshold
    status: "True"
    type: Error
```

Monitoring platform health on Red Hat OpenShift using Kubernetes events

Monitor the health of your API Connect deployment by viewing the Kubernetes events that are generated for every status change in each subsystem CR.

What are the Kubernetes events?

The CR for every subsystem of API Connect has a status condition section, which is regularly updated by the API Connect operator with the current status. The API Connect operator additionally generates a Kubernetes event whenever there is a change in the CR status.

Events are enabled in API Connect operator for the following resources.

- `APIConnectCluster` CR
- `ManagementCluster` CR
- `GatewayCluster` CR
- `AnalyticsCluster` CR
- `PortalCluster` CR

Two types of events are generated when the CR status changes:

- `Normal` - Indicates that the status change is not causing any issues.
- `Warning` - Indicates that there a problem that requires your attention.

You can automatically monitor the status condition in your existing alerting system, or by integrating the Kubernetes events into a third-party alerting solution. For more information, see the following blog post: How to use Kubernetes events for effective alerting and monitoring.

Viewing the events

The default retention period of events in Red Hat OpenShift is 3 hours (controlled by **kube-apiserver**). To view the events, complete the following steps:

1. In the Web UI, click Operators > Installed Operators > IBM API Connect > API Connect Clusters.
2. Select an instance by clicking its name: Management cluster, Gateway cluster, Portal cluster, or Analytics cluster. If you installed using the top-level **APIConnectCluster** CR, you can additionally select API Connect cluster.
3. Select the Events tab to see all of the events that were generated for that instance.

Monitoring on Cloud Pak for Integration

Monitor your API Connect deployment on Cloud Pak for Integration.

See:

- **Monitoring the API Connect cluster on Cloud Pak for Integration**
  Monitor the status of the API Connect cluster on Cloud Pak for Integration using either the command line or the IBM Cloud Pak Platform UI.
- **Monitoring Postgres disk usage on Cloud Pak for Integration**
  In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.

Monitoring the API Connect cluster on Cloud Pak for Integration

Monitor the status of the API Connect cluster on Cloud Pak for Integration using either the command line or the IBM Cloud Pak Platform UI.

In Cloud Pak for Integration, the API Management capability is provide by API Connect. You deploy the API Connect subsystems on Cloud Pak for Integration with the **APIConnect** operator and the **apiconnectcluster** CR. The CR contains a status section that is regularly updated by the operator to display the current status of the all the API Connect subsystems.

When you finish deploying API Connect, you can monitor the status of **apiconnectcluster** using the command line or the OpenShift web console.

- Monitoring the API Connect cluster using the command line
- Monitoring the API Connect cluster using the Platform UI

Note: You can also monitor the disk usage of Postgres microservices. The **APIConnect** operator continuously tracks the disk usage of postgres microservices and provides useful information in the **ManagementCluster** custom resource. For information on viewing the postgres disk status, see Monitoring Postgres disk usage on Cloud Pak for Integration.

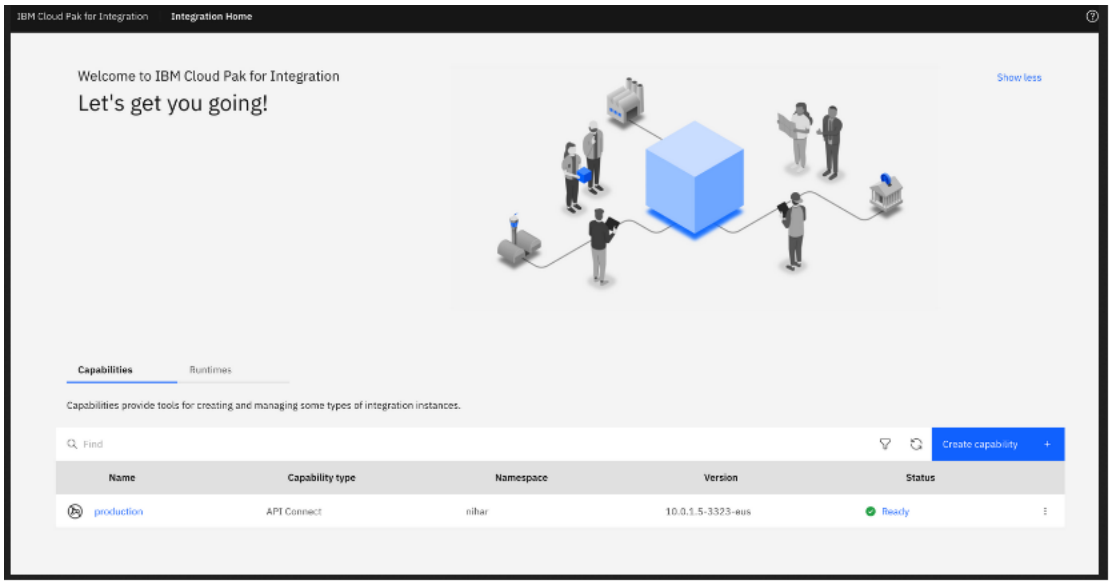
Monitoring the API Connect cluster using the command line

Run the following command to display the status of the API Connect cluster:

```
oc get apiconnectcluster -n <APIC_namespace>
```

The response looks like the following example:

```
NAME          READY   STATUS    VERSION         RECONCILED VERSION    AGE
production    7/7     Ready     10.0.8.0        10.0.8.0-3323     24h
```



The following list explains the values in the response:

- **NAME**: Name of the API Connect instance (in the example, the instance name is "production").
- **READY**: Current number of subsystems and components that are running **/** Expected number of subsystems and components that should be running.
- **STATUS**: Current status of API Connect.
  If the status says **Warning**, then run **oc describe apiconnectcluster -n** ***<namespace>*** and check for more details in the **Status** sections.

- **VERSION**: API Connect version specified in the CR's **spec.version** setting.
- **RECONCILED VERSION**: Current API Connect version.
- **AGE**: Age of the **apiconnectcluster** CR.

Monitoring the API Connect cluster using the Platform UI

1. Start the Platform UI.
2. Click the Integration instances tab.
3. Locate the "API Connect" capability that uses the instance name that you specified as the Name during installation.
   A healthy API Connect deployment displays "Ready" in the Status column

4. Click the status value to display information about the current conditions, as in the following image:

A healthy deployment displays "True" for the "Ready" status.

During a fresh install, an upgrade or a day-2 operation (such as a Management backup S3 configuration change), the **apiconnectcluster** CR status might change to a different state depending on the action, but ultimately it should always reach the **Ready** status.

Monitoring Postgres disk usage on Cloud Pak for Integration

In API Connect, you can monitor the disk space that is used by the Postgres database in the Management subsystem.

The Postgres database is the core database used in the Management subsystem. It is important to monitor the Postgres disk usage to avoid running out of space and causing an outage in your deployment.

The **APIConnect** operator tracks the current disk usage of the Postgres components, and regularly updates the **ManagementCluster** CR's status. When one or more of the Postgres components occupy 60% of the PVC (persistent volume claim) capacity, the **APIConnect** operator changes the CR's status from **Running** to **Warning**.

Important: If the Postgres disk usage reaches 80%, then the **APIConnect** operator brings down Postgres. If this situation occurs, contact IBM Support.
Note that there are various types of storage classes which can be used to deploy Management subsystem; for example, **local-storage** or **ceph block**. When **local-storage** is used, the entire disk is allocated to the worker node. In some cases, before the **APIConnect** operator reacts to an 80% usage condition, Kubernetes itself might face disk pressure and start evicting pods.

Viewing the current disk usage

The **ManagementCluster** instance includes the **.status.postgresDataStats** field, where the operator displays the current disk usage of Postgres components. Run the following command to get the disk usage:

```
oc get mgmt <mgmt-cr-name> -o json | jq .status.postgresDataStats
```

The response looks like the following example:

```
[
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
    "podName": "",
    "pvcCapacity": 51200,
    "pvcName": "",
    "pvcType": "WAL",
    "pvcUsed": 400,
    "pvcUsedPercentage": 8
  },
  {
    "instanceName": "<mgmt cr name>-site1-db-1",
```

```
    "podName": "",
    "pvcCapacity": 184320,
    "pvcName": "",
    "pvcType": "PostgreSQL",
    "pvcUsed": 95,
    "pvcUsedPercentage": 8
  }
]
```

Warning condition is populated at 60% usage

When one of the Postgres components uses 60% of its allocated space, the operator changes the overall status of the **ManagementCluster** CR and the **APIConnectCluster** CR to **Warning** with an appropriate warning message. The operator also updates the **postgresDataStats** section with the current data usage of the Postgres components.

Attention: If you encounter the **Warning** condition, contact IBM Support for help correcting the root cause.
To view the status from the command line, run the following command:

- **APIConnectCluster** CR:

  ```
  oc get apiconnect
  ```

  The following example response shows the warning status:

  ```
  NAME          READY
  STATUS    VERSION         RECONCILED VERSION    AGE
  production    Current WAL disk usage of production-mgmt-31be1757-postgres is 60 percent. DATABASE SHUTDOWN starts at 80
  percent utilization. Please contact IBM Support immediately.    Warning    10.0.8.0-eus    10.0.8.0-3394-eus    11d
  ```

- **ManagementCluster** CR:

  ```
  oc get mgmt
  ```

  The following example response shows the warning status:

  ```
  NAME               READY    STATUS    VERSION         RECONCILED VERSION    AGE
  production-mgmt    18/18    Warning   10.0.8.0-eus    10.0.8.0-3394-eus     43h

  Current WAL disk usage of m1-ed60c42d-postgres is 61 percent. DATABASE SHUTDOWN starts at 80 percent utilization. Please
  contact IBM Support immediately
  ```

To view the status in IBM Cloud Pak Platform UI, click the Integration instances tab to see the status displayed next to the instance name

Click the status value (Warning, for this example) to display the Conditions list where a detailed message explains why the condition was set:

Error condition is populated at 80% usage

When one of the Postgres components uses 80% of its allocated space, the operator changes the overall status of the `ManagementCluster` to `Error` and brings down Postgres avoid problems that can occur if the disk becomes completely filled.

Attention: If you encounter the `Error` condition, contact IBM Support for help correcting the root cause.
To view the status from the command line, run the following command:

- `APIConnectCluster` CR:

  ```
  oc get apiconnect
  ```

  The following example response shows the error status:

  ```
  NAME          READY
  STATUS    VERSION         RECONCILED VERSION    AGE
  production    Current disk usage is more than 80 percent. DATABASE will be shutdown. Please contact IBM Support
  immediately.    Error     10.0.8.0-eus    10.0.8.0-3394-eus     11d
  ```

- `ManagementCluster` CR:

  ```
  oc get mgmt
  ```

  The following example response shows the warning status:

  ```
  NAME                READY    STATUS    VERSION         RECONCILED VERSION    AGE
  production-mgmt     9/9      Error     10.0.8.0    10.0.8.0-3394     11d
  ```

To view the status in the Platform UI, click the Integration instances tab to see the status displayed next to the instance name

Click the status value (Error in this example) to display the Conditions list where a detailed message explains why the condition was set:

Obtaining simple health check data of Developer Portal sites by using a REST API call

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

About this task

You can use the site health REST API to determine whether a particular Developer Portal site is running. The site health API returns the current system time of the site if both the database and web server are running. This API is fast and puts no load on the system, so it is ideal for use with load balancers to help them determine where to route traffic.

Procedure

To call the site health REST API, append `/health` to the end of your Developer Portal site URL in your web browser, as follows:

```
site_url/health
```

Where `site_url` is the URL of the Developer Portal site that you want to check.
If both the database and web server of the site are running, the web browser returns the current system time. For example:

```
1511367695
```

If either the database or the web server of the site is not running, the web browser returns an error that the site can't be reached.

Logging

Configure logging for your deployment on Kubernetes.

See:

- **Gathering logs**
  How to gather the API Connect system logs and configuration information for use in troubleshooting and diagnostics.
- **Changing logging levels**
  You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

Gathering logs

How to gather the API Connect system logs and configuration information for use in troubleshooting and diagnostics.

When you open a support case for API Connect, system logs and environment data are normally required to help diagnosis. Several tools are used for gathering this data:

- The apic-mustgather tool collects all the logs and system information from the API Connect deployment.
- The apicops tool gathers extra debug information about the synchronization of the management subsystem with the gateway and portal services.

Installing the apic-mustgather tool

Download the latest version of the apic-mustgather tool.

1. To download apic-mustgather tool, run the following command:

   ```
   curl -L -O https://github.com/ibm-apiconnect/v10-postmortem/releases/latest/download/apic-mustgather
   ```

The **apic-mustgather** tool gathers the logs of the currently running processes. The logs have a maximum size and older log messages are not retained when the maximum size is reached. To ensure that the logs gathered cover the time when the problem occurred, reproduce the problem and then gather the logs without delay. Offboarding the logs to an external server is the best practice for long-term storage of log data.

Running the apic-mustgather tool

1. Copy the **apic-mustgather** tool to your API Connect container environment and give it execute permissions:

   ```
   chmod +x apic-mustgather
   ```

   If your API Connect deployment has subsystems in different environments, then copy **apic-mustgather** to each environment.

2. Re-create the problem that you want to diagnose.
3. Run the **apic-mustgather** tool:

   ```
   ./apic-mustgather
   ```

   The **apic-mustgather** tool gathers logs and status information for all API Connect resources and all related Kubernetes or OpenShift resources that it can find. The files are compressed to /tmp/apic-mustgather-*.tar.gz.

   If your API Connect deployment has subsystems in different environments, then run **apic-mustgather** in each environment.

   Note: The **apic-mustgather** checks if the apicops tool is present and if not then it attempts to download it. If you do not have the apicops tool locally and your environment does not have internet access to download it, then before you run **apic-mustgather** do the following:
   a. Download apicops.
   b. Give **apicops** execute permissions:

      ```
      chmod a+x apicops
      ```

   c. Copy **apicops** to the same location as **apic-mustgather**.
4. Upload the following to the support case:
   - /tmp/apic-mustgather-*.tar.gz
   - The steps to reproduce the problem (if applicable).

- The time the problem occurred.
- Screen capture of error (if applicable).

Changing logging levels

You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

About this task

For apim-v2 pods, the default logging settings do not include entry and exit trace and logging of large payloads.

Logging of large payloads is typically needed if you are logging **apim:webhookPayload** or other processes that log large variables.

You can also set the debug level without needing to restart the pods.

You can enable the settings through either the APIM deployment YAML file, the toolkit, or the REST APIs. Note, you must use the toolkit or REST API to set the debug level without restarting the pods.

Procedure

- Updating the settings in the APIM deployment YAML file
  Note: This action causes a pod restart.
  - The DEBUG variable works the same as prior releases.

    ```
    - env:
        - name: DEBUG
          value:
    audit,bhendi:error,bhendi:probe,bhendi:flags,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:
    *
    ```

    To enable entry and exit trace, add **trace:*** to the start of the debug string:

    ```
    - env:
        - name: DEBUG
          value: trace:*,audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:webhookAudit,bhendi:cassandra-
    transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:taskmanager:info
    ```

  - To enable large object logging:

    ```
    - env:
        - name: VELOX_LOG_FULL_PAYLOAD
          value: "true"
    ```

- Updating the settings by using the toolkit
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  apic log-spec:get
  apic log-spec:update  LOG_SPEC_FILE
  ```

  Where the spec file contains:

  ```
  {"specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}
  ```

- Updating the settings by using the REST API
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  GET /cloud/api/log-spec
  PUT /cloud/api/log-spec
  ```

  For example, to set debug level and large objects logging:

  ```
  curl -k https://172.16.140.212:3003/api/cloud/log-spec -X PUT -H "Authorization: Bearer $BEARER"
      -H "Accept: application/json" -d '{"specification":
  "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error","large_objects": true}'
      -H "Content-Type: application/json"
  ```

  The command responds with:

  ```
  {
      "specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error",
      "large_objects": true,
      "message": "Successfully changed the log specification on all apim-v2 pods. Success on IP(s): 172.16.140.212,
  172.16.140.213"
  }
  ```

  Note: The response might include the following warning, which can be ignored:

  ```
  WARNING: Could not change the log specification on all apim-v2 pods. Success on IP(s): 4.5.6.7  Failed on IP(s): 1.2.3.4
  ```

  To view the REST APIs for logging, go to API Connect REST APIs, and select IBM API Connect Platform - Cloud Management API 2.0.0 reference > Resource: Log Spec.

Troubleshooting

Troubleshooting problems with your API Connect subsystems.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
For common operational problems with API Connect, such as UI login failure, or published APIs not running on your gateways, see: Troubleshooting API Connect.

For problems with the analytics subsystem, see Troubleshooting analytics.

For problems with the portal subsystem, see Troubleshooting the developer portal.

To run a power-cycling check on OpenShift and Cloud Pak for Integration, see Power-cycling check on OpenShift and Cloud Pak for Integration.

Power-cycling check on OpenShift and Cloud Pak for Integration

If you cycle the power on an API Connect cluster that is deployed on OpenShift or Cloud Pak for Integration, you might need to reset the IP address for the **`kubernetes.io/hostname`**.

About this task

You will know there is a problem if you cycle the power for the cluster and receive an error, or find that the deployment remains in the **`pending`** state indefinitely because some of the pods failed to start. Complete the following steps to resolve the problem:

Procedure

1. Run the following command to check the label on the worker nodes:

   ```
   oc get nodes -l kubernetes.io/hostname=localhost
   ```

   If the response shows the following message, then the power cycle did not cause a problem and you can skip the rest of this task:

   ```
   No resources found
   ```

   If the response looks like the following example (the IP address will be different), proceed to the next step:

   ```
   NAME                                         STATUS   ROLES    AGE   VERSION
   ip-233.252.0.0.us-west-1.compute.internal    Ready    worker   27h   v1.19.0+8d12420
   ```

2. Run the following command to correct the problem:

   ```
   for i in $(oc get nodes -l kubernetes.io/hostname=localhost|grep worker|awk '{print $1}'); do echo $i;  oc label nodes $i
   kubernetes.io/hostname=`echo $i|awk -F'.' '{print $1}'` --overwrite=true; done
   ```

Uninstalling API Connect

You can uninstall a Kubernetes deployment of API Connect.

About this task

You can choose to uninstall individual API Connect subsystems or you can uninstall the complete API Connect deployment. You can delete Custom Resource Definitions, Persistent Volumes, service accounts, secrets, operators and the namespace. Use one of the following topics.
Note: For information about how to maintain a two data center deployment, see Maintaining a two data center deployment.

- **Uninstalling API Connect subsystems**
  You can individually uninstall API Connect subsystems that have been deployed on Kubernetes.
- **Removing API Connect**
  You can remove all parts of the API Connect deployment on Kubernetes.
- **Removing API Connect on OpenShift or Cloud Pak for Integration**
  Remove your entire API Connect deployment on OpenShift or Cloud Pak for Integration.

Uninstalling API Connect subsystems

You can individually uninstall API Connect subsystems that have been deployed on Kubernetes.

Before you begin

If you want to disable the analytics subsystem without uninstalling it, see Shutting down the analytics subsystem.

About this task

- To delete the API Connect deployment in a Kubernetes runtime environment, you must use the Kubernetes command-line tool, kubectl.
- The API Connect operator and DataPower operator pods are needed to uninstall subsystems individually.

- If need to retain data to re-use during a re-installation later, follow the backup and restore procedures Backing up, restoring, and disaster recovery.
- If you want to delete **all** of API Connect, do not use this topic. Instead, see Removing API Connect.

Procedure

1. Uninstall the Management subsystem
   a. Save the management subsystem name:

      ```
      kubectl get mgmt -n <namespace> -o yaml
      ```

      This command returns the YAML format of the management custom resource. Make a note of the name.

   b. Delete the Management Subsystem.

      ```
      kubectl delete mgmt --all -n <namespace>
      ```

      Important:
      If your deployment uses default namespaces be cautious when using **`kubectl delete <entity> --all`** commands. There can be other pods, services, and more in the default namespace. When using the default namespace, keep in mind that using **`kubernetes delete <entity> --all`**, where **`<entity>`** can delete non-APIC entities, such as **`sa`** (Service Accounts), **`secrets`**, **`rolebindings`**, etc.

      The Management CR deletion will take some time because the apiconnect operator must delete the Postgres cluster.

   c. Manually delete secrets and PVCs:
      i. Get all of the secrets that use the management subsystem name (which you determined in Step 1.a):

         ```
         kubectl get secrets -n <namespace> | grep <management-subsystem-name>
         ```

      ii. For each secret that uses the management subsystem name, run the following command to delete the secret:

         ```
         kubectl delete secrets <secret_name> -n <namespace>
         ```

      iii. Get all the PVCs that use the management subsystem name:

         ```
         kubectl get pvc -n <namespace> | grep <management-subsystem-name>
         ```

      iv. For each PVC that uses the management subsystem name, run the following command to delete the PVC:

         ```
         kubectl delete pvc <pvc_name> -n <namespace>
         ```

   d. If management subsystem backup and restore CRs are left stale, delete them also:
      i. Get the names of the backup CRs:

         ```
         kubectl get Backup -n <namespace>
         ```

      ii. Delete the backup CRs:

         ```
         kubectl delete Backup <backup_cr_name> -n <namespace>
         ```

      iii. Get the names of the restore CRs:

         ```
         kubectl get ManagementRestore -n <namespace>
         ```

      iv. Delete the restore CRs:

         ```
         kubectl delete ManagementRestore <restore_cr_name> -n <namespace>
         ```

      Note: If you have management backup CRs from V10.0.6.0 or earlier, delete those too:
      i. Get the name of the backup CR:

         ```
         kubectl get mgmtb -n <namespace>
         ```

      ii. Delete the backup CR:

         ```
         kubectl delete mgmtb <backup_cr_name> -n <namespace>
         ```

      iii. Get the name of the restore CR:

         ```
         kubectl get mgmtr -n <namespace>
         ```

      iv. Delete the restore CR:

         ```
         kubectl delete mgmtr <restore_cr_name> -n <namespace>
         ```

2. Uninstall Analytics subsystem
   a. Delete the Analytics subsystem, the Analytics backup, and the Analytics restore CRs.

      ```
      kubectl delete a7s --all -n <namespace>
      kubectl delete a7b --all -n <namespace>
      kubectl delete a7r --all -n <namespace>
      ```

   b. Manually delete the Analytics secrets:

      ```
      kubectl delete secrets <secret_name> -n <namespace>
      ```

      for each of the following secrets:

      ```
      analytics-ai-endpoint
      analytics-ca
      analytics-client
      analytics-server
      ```

c. Manually delete analytics Persistent Volume Claims (PVCs):

```
kubectl delete pvc <pvc_name> -n <namespace>
```

for PVCs with the following naming pattern:

```
data-analytics-storage
```

3. Uninstall the Developer Portal subsystem
   a. Delete the Developer Portal subsystem, and the Portal backup and restore CRs.

```
kubectl delete ptl --all -n <namespace>
kubectl delete pb --all -n <namespace>
kubectl delete pr --all -n <namespace>
```

   b. Manually delete Developer Portal secrets:

```
kubectl delete secrets <secret_name> -n <namespace>
```

for secrets with the following naming pattern:

```
portal-admin
portal-admin-client
portal-ca
portal-client
portal-db-ca
portal-encryption-key-...
portal-server
portal-web
```

   c. Manually delete these Developer Portal PVCs:

```
kubectl delete pvc <pvc_name> -n <namespace>
```

for PVCs with the following naming pattern:

```
admin-portal-...-www-...
backup-portal-...-www-...
db-portal-...-db-...
dblogs-portal-...-db-...
web-portal-...-www-...
```

4. Delete the DataPower Gateway subsystem.

```
kubectl delete gw --all -n <namespace>
```

Note: The following entries include both Multi-Protocol Gateway Service (v5-compatible) and API Gateway settings. Names that include "gwv5" refer to the Multi-Protocol Gateway Service (v5-compatible), and names that include "gwv6" refer to the API Gateway.

   a. Delete Service Accounts.

```
kubectl delete sa <service_account> -n <namespace>
```

for each of the following Service Accounts:

```
gwv5-datapower
gwv6-datapower
```

   b. Delete Secrets.

```
kubectl delete secrets <secret_name> -n <namespace>
```

for secrets with the following naming pattern:

```
gwv5-datapower-token-...
gwv5-dpm-sa-token-...
gwv5-endpoint
gwv5-manager-endpoint
gwv6-datapower-token-...
gwv6-dpm-sa-token-...
gwv6-endpoint.
gwv6-manager-endpoint
```

   c. Delete PVCs.

```
kubectl delete pvc <pvc_name> -n <namespace>
```

for PVCs with the following naming pattern:

```
gwv5...
gwv6...
```

Removing API Connect

You can remove all parts of the API Connect deployment on Kubernetes.

About this task

These instructions completely remove API Connect, including PVCs and secrets.

- To delete the API Connect deployment in a Kubernetes runtime environment, you must use the Kubernetes command-line tool, kubectl.
- You must run the commands in the order shown in the procedure on this page. If you run commands out of order, you might encounter a problem where the deletion of namespaces hangs.
- If you want to retain the PVCs, which contain some of the data you built up when using the application, you must also keep the associated secret used to decrypt the data. To do this, you must backup each subsystem, and then uninstall the subsystems individually. In this case, do not use the instructions on this page. Instead, see Uninstalling API Connect subsystems.

Procedure

1. Delete all API Connect systems.

   ```
   kubectl delete apic --all -n <namespace>
   ```

   This command is the equivalent of deleting each of the individual subsystems one at a time, and also deleting all of their backup and restore CRs. The commands that run during this step are:

   - Subsystem CRs. For example:

     ```
     kubectl delete mgmt --all -n <namespace>
     kubectl delete a7s --all -n <namespace>
     kubectl delete ptl --all -n <namespace>
     kubectl delete gwv6 --all -n <namespace>
     ```

   - Backup and restore CRs:

     ```
     kubectl delete Backup --all -n <namespace>
     kubectl delete mgmtr --all -n <namespace>
     kubectl delete pb --all -n <namespace>
     kubectl delete pr --all -n <namespace>
     kubectl delete a7b --all -n <namespace>
     kubectl delete a7r --all -n <namespace>
     ```

     Note: If your deployment was previously on V10.0.6.0 or earlier, delete any pre-V10.0.7.0 management backup or restore CRs:

     ```
     kubectl delete mgmtb --all -n <namespace>
     kubectl delete mgmtr --all -n <namespace>
     ```

2. Delete the Operator deployments.

   ```
   kubectl delete deployment datapower-operator ibm-apiconnect -n <namespace>
   ```

3. Delete all Service Accounts in the namespace.
   Important:
   If your deployment uses default namespaces be cautious when using **`kubectl delete <entity> --all`** commands. There can be other pods, services, and more in the default namespace. When using the default namespace, keep in mind that using **`kubernetes delete <entity> --all`**, where <*entity*> can delete non-APIC entities, such as **`sa`** (Service Accounts), **`secrets`**, **`rolebindings`**, etc.

   ```
   kubectl delete sa --all -n <namespace>
   ```

4. Delete all Secrets in the namespace.

   ```
   kubectl delete secrets --all -n <namespace>
   ```

5. Delete all Rolebindings in the namespace.

   ```
   kubectl delete rolebindings --all -n <namespace>
   ```

6. Delete all Roles in the namespace.

   ```
   kubectl delete roles --all -n <namespace>
   ```

7. Clean up any remaining jobs.

   ```
   kubectl delete jobs --all -n <namespace>
   ```

8. Delete all PVCs in the namespace.

   ```
   kubectl delete pvc --all -n <namespace>
   ```

9. Delete Issuers in the namespace.
   Note that there might be none found.

   ```
   kubectl delete issuer --all -n <namespace>
   ```

10. Delete certificates in the namespace.
    Note that there might be none found.

    ```
    kubectl delete certificates --all -n <namespace>
    ```

11. If you are not using the default namespace, delete the Namespace
    Important: If your deployment uses the default namespace, do not delete it. There can be other pods, services, and more in the default namespace.

    ```
    kubectl delete ns <namespace>
    ```

12. Delete `validatingwebhookconfiguration`

    a. `kubectl get validatingwebhookconfiguration | awk /<ns>/'{print $1}' | xargs kubectl delete validatingwebhookconfiguration`

    b. `kubectl delete validatingwebhookconfiguration managements.validator.subsystem.apiconnect.ibm.com`

13. Delete `mutatingwebhookconfiguration`

    a. `kubectl get mutatingwebhookconfiguration | awk /$NS/'{print $1}' | xargs kubectl delete mutatingwebhookconfiguration`

    b. `kubectl get mutatingwebhookconfiguration | awk /apicop-management-defaulter/'{print $1}' | xargs kubectl delete mutatingwebhookconfiguration`

14. Delete the Apiconnect CRDs (custom resource definitions)

```
kubectl delete crd analyticsbackups.analytics.apiconnect.ibm.com
kubectl delete crd analyticsclusters.analytics.apiconnect.ibm.com
kubectl delete crd analyticsrestores.analytics.apiconnect.ibm.com
kubectl delete crd datapowerservices.datapower.ibm.com
kubectl delete crd gatewayclusters.gateway.apiconnect.ibm.com
kubectl delete crd backups.management.apiconnect.ibm.com
kubectl delete crd managementclusters.management.apiconnect.ibm.com
kubectl delete crd managementrestores.management.apiconnect.ibm.com
kubectl delete crd natsclusters.nats.io
kubectl delete crd natsserviceroles.nats.io
kubectl delete crd natsstreamingclusters.streaming.nats.io
kubectl delete crd portalbackups.portal.apiconnect.ibm.com
kubectl delete crd portalclusters.portal.apiconnect.ibm.com
kubectl delete crd portalrestores.portal.apiconnect.ibm.com
```

    Note: If your deployment was previously on V10.0.6.0 or earlier, delete any pre-V10.0.7.0 management backup or restore CRs:

```
kubectl delete crd managementbackups.management.apiconnect.ibm.com
```

15. Delete EDB CRDs:

    a. Get a list of the EDB CRDs:

```
kubectl -n <namespace> get crds | grep enterprisedb
```

    Expected output:

```
backups.postgresql.k8s.enterprisedb.io                            2023-07-26T14:09:51Z
clusters.postgresql.k8s.enterprisedb.io                           2023-07-26T14:09:51Z
poolers.postgresql.k8s.enterprisedb.io                            2023-07-26T14:09:59Z
scheduledbackups.postgresql.k8s.enterprisedb.io                   2023-07-26T14:10:02Z
```

    b. Delete the EDB CRDs:

```
kubectl -n <namespace> delete crd <crd name>
```

    where *<crd name>* is the name of each CRD output in step 15.a.

16. If you installed cert-manager and want to remove it now, complete the following steps:
    Warning: If you are using shared clusters for API Connect with a common cert manager, be aware that this step removes the components of the cert manager from cluster wide scope.

    a. Delete the cert-manager

```
kubectl delete deploy --all -n cert-manager
kubectl delete service --all -n cert-manager
kubectl delete sa -n cert-manager --all
kubectl delete secrets -n cert-manager --all
kubectl delete APIService v1beta1.webhook.cert-manager.io -n cert-manager
kubectl delete MutatingWebhookConfiguration cert-manager-webhook -n cert-manager
kubectl delete ValidatingWebhookConfiguration cert-manager-webhook -n cert-manager
kubectl delete ns cert-manager
```

    b. Delete cert-manager CRDs

    - Delete the cert-manager CRDs with the following:

```
kubectl delete crd issuers.cert-manager.io
kubectl delete crd certificaterequests.cert-manager.io
kubectl delete crd certificates.cert-manager.io
kubectl delete crd challenges.cert-manager.io
kubectl delete crd clusterissuers.cert-manager.io
kubectl delete crd orders.cert-manager.io
```

    - Older API Connects versions may have cert-manager CRDs from an older version of cert-manager which had a different name, delete these CRDs with the following:

```
kubectl delete crd certificaterequests.certmanager.k8s.io
kubectl delete crd certificates.certmanager.k8s.io
kubectl delete crd challenges.acme.certmanager.k8s.io
kubectl delete crd clusterissuers.certmanager.k8s.io
kubectl delete crd issuers.certmanager.k8s.io
kubectl delete crd orders.acme.certmanager.k8s.io
```

Removing API Connect on OpenShift or Cloud Pak for Integration

Remove your entire API Connect deployment on OpenShift or Cloud Pak for Integration.

About this task

These instructions completely remove API Connect, including PVCs and secrets.

Attention: Run the commands in the sequence shown on this page. If you run commands out of sequence, you might encounter a problem where the deletion of namespaces hangs.

Procedure

1. If Event Endpoint Management is installed, run the following command to determine the name of your Event Endpoint Management instance:

   ```
   oc get eem -n <APIC-namespace>
   ```

2. If you are using a top-level CR, run the following command to determine the name of your API Connect instance:

   ```
   oc get apiconnectcluster -n <APIC-namespace>
   ```

3. If you are using a top-level CR, run the following command to delete the API Connect operands (subsystems):

   ```
   oc delete apiconnectcluster <name_of_apic_instance> -n <APIC-namespace>
   ```

4. Run the following command to delete the API Connect backup and restore CRs:

   ```
   oc delete apic --all -n <APIC-namespace>
   ```

5. Run the following command to delete the secrets that are associated with your deleted API Connect cluster:

   ```
   oc get secrets --no-headers -n <APIC-namespace> | cut -d' ' -f1 | grep "^<first_10_characters_of_apic_instance_name>-" |
   xargs oc delete secret -n <APIC-namespace>
   ```

   Where *<first_10_characters_of_apic_instance_name>* refers to the name of your API Connect instance.

   Note: This step assumes that any secrets that you want to keep in your namespace do not have a name that starts with the same 10 first characters of the API Connect Cluster name.

6. If Event Endpoint Management is installed, run the following command to delete the secrets that are associated with your deleted Event Endpoint Management instance:

   ```
   oc get secrets --no-headers -n <APIC-namespace> | cut -d' ' -f1 | grep "^<first_10_characters_of_eem_instance_name>-" |
   xargs oc delete secret -n <APIC-namespace>
   ```

   Where *<first_10_characters_of_eem_instance_name>* refers to the name of your Event Endpoint Manager instance.

   Note: This step assumes that any secrets that you want to keep in your namespace do not have a name that starts with the same 10 first characters of the Event Endpoint Manager name.

7. Run the following commands to delete the API Connect secret rotation CRs for the cluster:

   ```
   oc delete mgmtsr -n <APIC-namespace>  --all
   oc delete ptlsr -n <APIC-namespace> --all
   ```

8. Optional: If you created a namespace specifically for API Connect, and are not using it for anything else, you can delete the namespace. If your API Connect operators are installed in this namespace, instead of in a shared global namespace, they are also deleted.

   ```
   oc delete ns <APIC-namespace>
   ```

   Deleting the namespace removes any remaining certificates and secrets.
   Note: Namespace deletion can get stuck, check that the namespace is deleted with:

   ```
   oc get ns <APIC-namespace>
   ```

   If the namespace is still present, to see why deletion is stuck, run:

   ```
   oc describe ns <APIC-namespace>
   ```

9. Optional: Delete the API Connect operator deployments.
   If your API Connect operator deployments are in a global namespace they are not deleted when your API Connect namespace is deleted. To delete the API Connect operators:
   a. Open the OpenShift web console and go to Installed Operators, in the namespace where the API Connect operators are installed.
   b. For each operator, click the options menu, and select Uninstall Operator.
   API Connect operator might have created a number of operand requests with IBM Cloud Pak foundational services (previously called Common Services) to deploy services such as Cert-Manager. In addition, API Connect requires the use of a DataPower Gateway, so the DataPower operator might be installed in the API Connect namespace. If those artifacts are no longer needed, uninstall them individually.
   Note: DataPower can be deployed on its own without API Connect. It is possible that the DataPower operator was installed for another purpose and not for use with API Connect, so check with your organization before you delete it.
   Deleting the operators from the web console ensures that related subscriptions, CSVs, and install plans are also removed.

VMware

Use the instructions in this section to install, upgrade, and maintain API Connect on VMware.

- **Planning your deployment**
  Before you install API Connect, understand deployment options and requirements for endpoints, load balancing, certificates, and firewalls.
- **Installing API Connect**
  Use these instructions to install API Connect on VMware.
- **Upgrading API Connect**
  Upgrade API Connect on VMware to a newer version.
- **Maintaining API Connect**
  You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

Planning your deployment

Before you install API Connect, understand deployment options and requirements for endpoints, load balancing, certificates, and firewalls.

- **Prerequisite skills for administering API Connect on VMware**
  The background knowledge and skills that are required to install and manage an API Connect VMware deployment.
- **Deployment overview for endpoints**
  When deploying API Connect, you will create one or more endpoints for the subsystems and then configure certificates or mutual TLS for most endpoints.
- **Planning your deployment topology and profiles**
  When you install on VMware, API Connect provides a choice of deployment configurations for capacity and high availability (HA). These configurations are named 'deployment profiles' and there are several pre-defined profiles to choose from.
- **Enable JWT instead of mTLS**
  Use JWT to authenticate communication between API Connect subsystems, instead of mTLS.
- **Firewall requirements on VMware**
  Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on VMware.
- **Load balancer configuration in a VMware deployment**
  When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect OVA deployment.
- **Multiple data center deployment strategies**
  Strategies for deploying API Connect on VMware across multiple data centers.
- **Planning your analytics deployment**
  Plan your API Connect analytics deployment by reviewing options for topology, data modifications, and storage.
- **API Connect TLS certificate best practices**
  Best practices for configuring and managing TLS certificates in an API Connect deployment on VMware.

Prerequisite skills for administering API Connect on VMware

The background knowledge and skills that are required to install and manage an API Connect VMware deployment.

The following list provides an idea of the concepts and technologies that the API Connect administrator should be familiar with:

- VMware: Deploying OVA files and taking VM snapshots.
- Linux: File permissions, editing files with the vi editor, redirecting command output to file.
- Network concepts: FQDNs, ports, firewalls.
- TLS: CAs, certificate chains, mTLS.

The examples in this list do not include all background knowledge that is required, but are intended to give a general idea of the skills that are needed to plan, install, and maintain an API Connect deployment.

Deployment overview for endpoints

When deploying API Connect, you will create one or more endpoints for the subsystems and then configure certificates or mutual TLS for most endpoints.

Configuring endpoints

Subsystem	Endpoints	Description	Certificates
Management	cloud-admin-ui	Configured using the **apicup** command. Endpoint on the management server for communication with the Cloud Manager user interface.	cloud-admin-ui
	api-manager-ui	Configured using the **apicup** command. API Manager URL endpoint on the management server for communication with the API Manager user interface.	api-manager-ui
	consumer-api	Configured using the **apicup** command. Platform REST API endpoint for running consumer APIs on the management server.	consumer-api
	platform-api	Configured using the **apicup** command. Platform REST API endpoint for running admin and provider APIs on the management server.	platform-api
	hub	Automated Testing Behavior API endpoint. External Ingress, port 443	hub-endpoint
	consumer-catalog-ui	Configured using the **apicup** command. Consumer Catalog URL endpoint on the management server for communication with the Consumer Catalog User Interface	consumer-catalog-ui
Portal	portal-admin	Configured using the **apicup** command. Corresponds to management endpoint entered in Cloud Manager. Requires a TLS profile configured with mutual TLS.	mutual TLS
	portal-www	Configured using the **apicup** command. Portal Web site URL entered in the Cloud Manager UI. Used publicly to access Portal.	portal-www-ingress
Analytics	analytics-client	This is a legacy certificate, it is not used from v10.0.5 onwards.	mutual TLS
	analytics-ingestion	Configured using the **apicup** command. The analytics-ingestion endpoint must be entered in the Cloud Manager UI when registering the analytics service. It is also used by the gateway service to push data to the analytics service. Requires a TLS profile configured with mutual TLS.	mutual TLS
Gateway	apic-gw-service	Configured using the **apicup** command. This is the endpoint the gateway uses for network communication. Enter this endpoint as the management endpoint entered in Cloud Manager UI.	apic-gw-service-ingress
	api-gateway	Configured using the **apicup** command. This is the endpoint the gateway uses for API traffic. Enter this endpoint as the API Invocation Endpoint in Cloud Manager UI.	api-gateway-ingress

The endpoints are configured by the installation Operator. They are set for each subsystem. Endpoints are also entered when configuring the topology for the Gateway, Portal, and Analytics subsystems in Cloud Manager.

For instructions on configuring endpoints and installing into an OVA environment, see Installing API Connect.

Configuring certificates

All TLS certificates are automatically generated, but you can customize your user-facing certificates, see API Connect TLS certificate best practices.

Configuring mutual TLS

Mutual TLS is used for communication between API Connect subsystems. Configure inter-subsystem communication in your TLS profiles in the Cloud Manager UI. See Creating a TLS Server Profile.

Configuring a proxy

If a Developer Portal is deployed externally to the management server zone, it does not have access to the consumer and product APIs. You need to configure a proxy to enable communication. For more information, see Configuring a proxy.

Planning your deployment topology and profiles

When you install on VMware, API Connect provides a choice of deployment configurations for capacity and high availability (HA). These configurations are named 'deployment profiles' and there are several pre-defined profiles to choose from.

High availability versus disaster recovery

High availability focuses on minimizing the loss of service that is experienced by users during a hardware or software failure. Disaster recovery (DR) focuses on the procedures for recovering a system after a catastrophic hardware, software, or operator failure. Consider the following two metrics:

Recovery Time Objective (RTO)
: The RTO is the time that it is acceptable for a system to be unavailable after a disaster.

Recovery Point Objective (RPO)
: DR solutions are usually based on restoring from a backup. This means that the system can only be recovered to the state it was in when the last backup was taken, and not to the state it was in at the instant the disaster occurred. The RPO measures how far back in time the recovery point is, and therefore how much new data is lost. An RPO of zero would assert that no data is lost, but such a solution is often a compromise against the cost and performance of the system.

To achieve high availability in your API Connect VMware deployment, the three replica deployment profiles should be used, where each API Connect component is distributed across three virtual machines (VMs). However, this topology requires a low network latency between the VMs that is often unachievable between geographically separated data centers. To overcome this limitation, API Connect provides a two data center deployment solution that has both a low Recovery Time Objective (RTO), and a low Recovery Point Objective (RPO).

Deployment options

API Connect is composed of three components: Management, Portal, and Analytics, and the DataPower Gateway supporting program, see API Connect components. Each of these components includes a set of deployment profiles to cover different capacity and availability requirements.
Note: Throughout this document, the management, portal, and analytics components, and the gateway supporting program are also referred to as "subsystems".
The naming convention of the deployment profiles is `nAxcB.mC` where:

- **nA** indicates the number (A) of VMs (nodes) that are deployed to support the profile. The term "node" is used to refer to a VM instance (n1 means one node, n3 means three nodes).
- **cB** indicates the minimum number of virtual cores (B) required on the VM to deploy the profile.
- **mC** indicates the minimum amount of memory (C) in GB required by the profile on the VM.

API Connect components have two profile types: one replica and three replica:

- The one replica profile is a single node profile and is also known as the `n1` profile. It consists of a single VM for each component. This deployment type is recommended for development or testing where high availability is not a requirement.
- The three replica profiles consist of a cluster of three VMs for each component. This profile is also referred to as the `n3` profile. Each VM runs a replica of the component's microservices, and if a VM fails, the replicas on the other two VMs continue serving requests.

The available profiles for the management, portal, and analytics components are:

- **Management**
  `n1xc4.m16`, `n3xc4.m16`.
- **Portal**
  `n1xc2.m8`, `n1xc4.m16`, `n1xc8.m16`, `n3xc3.m8`, `n3xc4.m8`, `n3xc8.m16`.
- **Analytics**
  `n1xc2.m16`, `n1xc4.m32`, `n1xc6.m48`, `n3xc4.m16`, `n3xc4.m32`, `n3xc6.m48`, `n3xc8.m64`.

For information about gateway CPU and memory, refer to *Deploying the OVA on a VMware hypervisor* in the appropriate version of the DataPower documentation.

Additional points:

- Deployment profiles do not have to be the same for each component. For example, you can have a three replica deployment of the management component that is configured with a one replica deployment of the portal component.

- It is possible to change the deployment profile of an existing installation, but all endpoints in your deployment must remain the same. This means that you should use a load-balancer or logical DNS records when you do the initial one replica deployment. For example, if you installed a one replica deployment and used the portal VM hostname as the portal management registration endpoint, this endpoint cannot change when you move it to a three replica deployment. For more information, see Changing deployment profiles on VMware. If you want to change the deployment profile and the endpoints, you can use the form factor migration procedure: Migrating from v10 to v10 on a different form factor.
- Multiple portal, analytics, and gateway component instances can be added with either configuration. For example, you can have a one replica management component that is configured with two portal services: a three replica portal component, and a one replica portal component.

Two data center disaster recovery

API Connect deployments can operate across two data centers in an active/warm-standby configuration. Each data center has a complete API Connect installation. The active data center processes all user operations. The warm-standby data center does not process user operations but maintains its management and portal component databases in synchronization with the active data center. If a failure occurs at the active data center, the warm-standby data center can become active with a manual failover operation. For more information on the two data center disaster recovery configuration, see: Two data center warm-standby deployment strategy on VMware.

Enable JWT instead of mTLS

Use JWT to authenticate communication between API Connect subsystems, instead of mTLS.

If your network infrastructure requires that load-balancers implement TLS termination, then mTLS between API Connect subsystems can be disabled and JSON Web Token (JWT) security can be used instead.
Note: Although mTLS is disabled, the network communication is still secured with standard TLS, which does not require passthrough to be enabled on load-balancers.
The following communication flows can be secured with JWT:

- Management initiated communication to portal, analytics, and gateway subsystems.
- Analytics ingestion: The flow of API event records from the gateway to the analytics subsystem.
  Note: If the gateway is under a high transaction load and sending many API events to the analytics subsystem, the enablement of JWT might impact the performance of your analytics subsystem. It is recommended to run performance tests under your expected analytics load before you decide to use JWT for the analytics ingestion path.

With JWT enabled, the portal, gateway, and analytics subsystems verify the JSON Web Token (JWT) sent from the management subsystem when it initiates communication with them. The analytics subsystem verifies the JWT sent from the gateway with incoming API event data. The subsystems that receive the token contact a JSON Web Key Set (JWKS) URL to verify it. The JWKS URL is hosted by the management subsystem, in a subpath of the management subsystem's platform REST API.

You can configure JWT instead of mTLS during installation, as documented in Installing API Connect, or you can configure JWT after installation: Use JWT security instead of mTLS between subsystems.

If you disable mTLS, you must enable JWT. It is not possible to configure API Connect with both mTLS and JWT disabled.

Firewall requirements on VMware

Diagram for port configuration, and list of active ports, for an IBM® API Connect deployment on VMware.

Required Ports between zones

The following network diagram example helps to explain which ports must be configured in an API Connect network. Specific ports must be configured to enable the communication between the various zones, both public and private, in a network.

The ports specified in the diagram are default ports. Check your deployment to understand which communication, if any, is configured to use non-default ports.

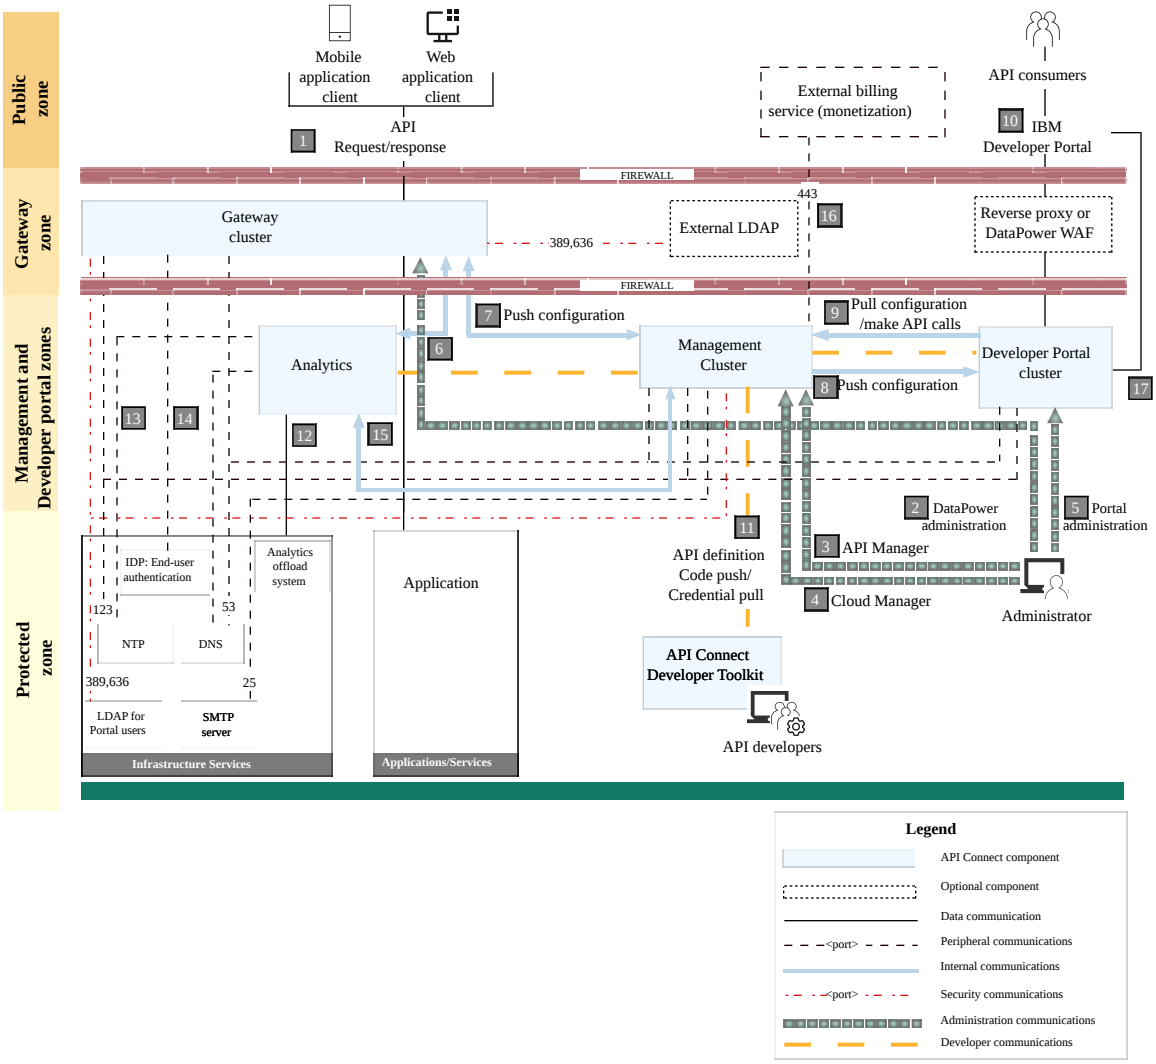


Table 1. Key for the network diagram example.
The following table lists the port numbers with a usage description.

	Usage description	Default port number
1	API request/response – Users invoking the provided APIs.	443 HTTPS from Public zone to Gateway zone
2	DataPower® administration – Internal operators who are managing the Gateway servers.	22 SSH, 9090 HTTPS from Protected zone to Gateway zone
3	API Manager – Internal business users who are defining and monitoring APIs.	443 HTTPS from Protected zone to Management zone
4	Cloud Manager – Internal operators who are administering the Cloud.	22 SSH, 443 HTTPS from Protected zone to Management zone
5	Developer Portal administration – Internal operators who are managing the Portal servers.	22 SSH, 443 HTTPS from Protected zone to Management zone
6	Gateway servers post traffic to Analytics service.	443 HTTPS from Gateway servers to Analytics service
7	Push configuration – Management servers communicate bi-directionally with Gateway servers.	3000 and 443 HTTPS Management servers to and from Gateway servers for webhook delivery. Port 3000 is the default port for apic-gw-service, and this is the port Management uses to communicate with Gateway. Port 443 is the default port for the platform-api endpoint, which apic-gw-service uses to communicate with Management.
8	Push configuration/webhooks – Management servers push configuration and webhooks to the Developer Portal.	443 HTTPS Management servers to Developer Portal servers for webhook delivery
9	Pull configuration/make API calls – Developer Portal servers pull configuration and call REST APIs.	443 HTTPS from Developer Portal servers to Management servers within Management zone
10	Developer Portal – External developers who are accessing the Developer Portal.	443 HTTPS from Public zone to Developer Portal management zone. The reverse proxy/DataPower WAF for incoming web traffic to the Developer Portal cluster must be a transparent proxy - no modification of the portal URL, port, host name or path is allowed.
11	Push API definition to Management server. Pick up credential for microservice code push.	443 HTTPS from Protected zone to Management zone
12	Analytics offload	Port will depend on type of plugin and protocol used for the offload. Some possible protocols are: HTTP, HTTPS, TCP, UDP, KAFKA
13	Analytics accesses NTP	Standard NTP

	Usage description	Default port number
14	Analytics access DNS	Standard DNS
15	Management service queries Analytics service	443 HTTPS within Management zone
16	External billing service – Management cluster connecting to external billing service (when configured for billing). If you are using Stripe as your external billing service, you must enable connections with the Stripe API at: https://stripe.com/files/ips/ips_api.json. You can also view the Stripe IP addresses at the following URL: https://stripe.com/docs/ips.	443 HTTPS from Management zone to Public zone
17	Developer Portal cluster must be able to access its own site endpoints.	443 HTTPS from Portal zone to Public zone

Firewall port requirements on VMware

The following tables lists ports that must be open in both cluster and non-clustered deployments.

Note that clustered VMware environment deployments require additional ports. See Firewall enabled ports for clustered OVA deployments

Table 2. Firewall port requirements common to all subsystems

Subsystem	Ports and description
Ports that must be open on all API Connect subsystems	The following ports must be open on the Management Server, Analytics, and Developer Portal subsystems, whether in a cluster or not. • 53 (outbound) DNS • 123 (outbound) NTP • 179 (inbound and outbound) BIRD routing daemon - VMware environments (OVA) deployments. Used for communication over TCP between servers either within the same subsystem or across different subsystems. • 443 (inbound and outbound) Used by all subsystems for communication with other subsystems • 2020 (inbound) status request. Used for communication over TCP between servers within the same subsystem. • 9177 (inbound and outbound) Member list (group membership) for API Connect`apic` daemon communication. Used for communication over both TCP and UDP, between servers within the same subsystem. • 9178 (inbound and outbound) API server, for API Connect `apic` daemon communication. Used for communication over TCP from between servers, both within the same subsystem and across different subsystems. Also used for communication between the `apicup` configuration utility and servers (this is the only port used by `apicup`).

Each subsystem uses ports in addition to the ports in Table 2. See the following table.

Table 3. Additional firewall port requirements for each subsystem

Subsystem	Ports and description
Management Service	Management Service uses the ports in Table 2 plus: • 22 remote backup server port (inbound, configurable) If backups are configured to use another port, ensure that the port is open. See Backing up and restoring on VMware. Note: this port does not have to be open between the management server and the portal server. • SMTP server port (outbound), typically 25 • 161 (inbound) SNMP. Over UDP. Not needed if SNMP not enabled. • LDAP server port (if using LDAP user registry), typically 389 (outbound) • In a clustered deployment, the Management Services uses additional ports. See Firewall enabled ports for clustered OVA deployments. The Automated test behavior application must be able to invoke (outbound) any port that a test system might present an API on. It can be bound to a particular port (if it is the same in all environments) or to a range of ports (to cover all of the ports it might invoke).
Developer Portal	The Developer Portal uses the ports listed in Table 2, plus: • 161 (inbound) SNMP. UDP protocol. Not needed if SNMP not enabled. • 22 - A remote backup server port (inbound, configurable) If backups are configured to use another port, ensure that the port is open. See Backing up and restoring the portal subsystem. Note: this port does not have to be open between the management server and the portal server. • In a clustered deployment, the Developer Portal uses additional ports. See Firewall enabled ports for clustered OVA deployments.
Analytics	The Analytics subsystem uses the ports listed in Table 2, plus: • 161 for SNMP is required for both non-clustered and clustered deployments. UDP, inbound only. Not needed if SNMP not enabled. • In a non-clustered deployment, no additional ports are required. • Analytics supports an optional configuration for offload of data. This configuration might require additional outbound ports to be open. • In a clustered deployment, the Analytics subsystem uses additional ports. See Firewall enabled ports for clustered OVA deployments.
Gateway Server	The Gateway Server uses these ports in both non-clustered and clustered deployments: • 161 (inbound) SNMP. UDP protocol. Not needed if SNMP not enabled. • 162 (outbound) SNMP traps • 3000 (inbound) Gateway Service local port (configurable) • 5550 (inbound) XML management port (configurable) • 5554 (inbound) REST management port (if enabled; configurable) • 9022 (inbound) Gateway SSH (if enabled; configurable) • 9090 (inbound) Web GUI console (if enabled; configurable) • 9443 (inbound) Gateway local port (configurable) • In a clustered deployment, the Gateway Server uses additional ports. See Firewall enabled ports for clustered OVA deployments.

Communications inside the Gateway cluster

There are a number of important points to note regarding the communications within the Gateway cluster.

- We advise that you use the same port for all Gateway servers within a cluster.
- Gateway servers communicate with each other to synchronize invocation counts.
- All Gateway servers in a Gateway cluster must be able to reach all of the other Gateway servers in the same Gateway cluster.
- Gateway servers in a Gateway cluster do not directly communicate with Gateway servers in a different Gateway cluster.
- All Gateway servers must be able to reach the management subsystem platform API endpoint, which was configured during the installation of your API Connect environment.

Ethernet interface usage

To separate network traffic, you can use two or more Ethernet interfaces on the DataPower appliance on which a Gateway server is installed. For example, you can use one interface for internal IBM API Connect communications, and another for processing incoming API calls.

Port requirement for Stripe billing service

All Management servers and Developer Portal servers must be able to communicate HTTPS content with the external billing service when billing is configured. If you are using Stripe as your external billing service, you must enable HTTPS communication on port 443 with the Stripe API: https://stripe.com/files/ips/ips_api.json.
Note: API Connect does not support using webhooks with Stripe. You can see a list of the Stripe IP addresses at: https://stripe.com/docs/ips.

- **Firewall enabled ports for clustered OVA deployments**
  In a clustered OVA deployment of API Connect, specific ports must be configured for communication between members of each API Connect subsystem.
- **Load balancer ports for clustered OVA deployments**
  When you deploy a load balancer with a clustered deployment, in a VMware environment, you must ensure that the necessary ports are open.

Related concepts

- Firewall enabled ports for clustered OVA deployments
- Load balancer ports for clustered OVA deployments

Firewall enabled ports for clustered OVA deployments

In a clustered OVA deployment of API Connect, specific ports must be configured for communication between members of each API Connect subsystem.

OVA deployments require the common ports that are listed in Firewall requirements. When the VMs are clustered, additional ports are used for communication between the members of the subsystems in the cluster.

All ports must be enabled inbound and outbound.

Table 1. Firewall enabled ports for clustered VMware environment deployments

Subsystem	Ports
Ports that must be open between all subsystem VMs	442, 2379, 2380, 6443, 6444, 9099, 10248, 10249, 10250,10251, 10252, 10254, 10256,10257, 10259 These ports must be open between all servers within a given subsystem. For example, from management server to management server, or from portal server to portal server, or from analytics server to analytics server. These ports are not used for communication between subsystems. You might need additional ports for Kubernetes-proxied services. The default range is **30000 – 32767**. Since the ports in use can change dynamically, ensure that the default range is open.
Additional ports that must be open between Management Service VMs	Port 8088 is required if the Automated testing behavior application is deployed for the Management Service VMs.
Additional ports that must be open between Developer Portal VMs	3009, 3010, 3306, 3307, 4443, 4444, 4567, 4568, 30865
Additional ports that must be open between Gateway Service VMs	16380, 16381, 26380, 26381
Additional ports that must be open between Analytics VMs	No additional ports are needed.

These internal ports are not used for communication between VMs. Ensure that they are open on the VM server locally.

Table 2. Internal ports reserved by API Connect

Subsystem	Ports
Reserved local ports on all subsystem VMs	8383, 8686, 8080, 8443, 30000:59999
Management Service VMs	2000, 2001, 2002, 2005, 2006, 2007, 2008, 2022, 3003, 3004, 3006, 3007, 3011, 3023, 4150, 4151, 4171, 4222, 5432, 6222, 7777, 8084, 8222, 8404
Portal Service VMs	3058, 3059, 3060, 3061
Analytics VMs	4443, 5000, 5601, 9200, 9300

Note: The ports should support IP-in-IP (protocol 4), per https://docs.projectcalico.org/getting-started/kubernetes/requirements.

Load balancer ports for clustered OVA deployments

When you deploy a load balancer with a clustered deployment, in a VMware environment, you must ensure that the necessary ports are open.

The load balancer needs port 443 for all API Connect subsystems (Management, Analytics, Developer Portal, DataPower Gateway).

Load balancer configuration in a VMware deployment

When deploying API Connect for High Availability, it is recommended that you configure a cluster with at least three nodes and a load balancer. A sample configuration is provided for placing a load balancer in front of your API Connect OVA deployment.

Before you begin

Note:

- This article does not apply to the IBM® DataPower® Gateway component that is a part of the IBM API Connect solution.
- This article applies to third-party software that IBM does not control. As such, the software may change and this information may become outdated.

About this task

API Connect can be deployed on a single node cluster. In this case the ingress endpoints are host names for which the DNS resolution points to the single IP address of the corresponding node hosting a particular subsystem, and no load balancer is required. For high availability, it is recommended to have at least a three node cluster. With three nodes, the ingress endpoints cannot resolve to a single IP address. A load balancer should be placed in front of an API Connect subsystem to route traffic.

Because it is difficult to add nodes once endpoints are configured, a good practice is to configure a load balancer even for single node deployments. With the load balancer in place, you can easily add nodes when needed. Add the node to the list of servers pointed to by the load balancer to avoid changing the ingress endpoints defined during the installation of API Connect.

To support Mutual TLS communication between the API Connect subsystems, configure the load balancer with **SSL Passthrough** and **Layer 4** load balancing. In order for Mutual TLS to be performed directly by the API Connect subsystems, the load balancer should leave the packets unmodified, as is accomplished by Layer 4.

If you do not want to use mTLS between API Connect subsystems, then you can Enable JWT instead of mTLS.

Set endpoints to resolve to the load balancer
: When configuring a load balancer in front of the API Connect subsystems, the ingress endpoints are set to host names that resolve to a load balancer, rather than to the host name of any specific node. For an overview of endpoints, see Deployment overview for endpoints and certificates.

Use this example configuration as a guideline to determine the best way to configure the load balancer for your deployment.

Procedure

- **Appliance deployment**
  In this example configuration, the API Connect management, portal, analytics and gateway subsystems are deployed as three node clusters in Standard mode. An HAProxy load balancer is used. The load balancer is configured with ssl-passthrough and with upstream selection based on SNI. DNS resolution is configured to resolve the endpoints to the IP address of the load balancer. If a single HAProxy node is used, then all endpoints must resolve to the IP address of the single HAProxy. The following example endpoints require DNS resolution for this example:
  - api-manager-ui.sample.example.com
  - cloud-admin-ui.sample.example.com
  - consumer-api.sample.example.com
  - platform-api.sample.example.com
  - admin.portal.sample.example.com
  - web.portal.sample.example.com
  - analytics.ingestion.sample.example.com
  - api-gateway.sample.example.com
  - apic-gw-service.sample.example.com

  Following is an example HAProxy configuration for one HAProxy node distributing traffic to management and portal clusters:

  Note:
  - When you configure a load balancer in front of a management subsystem, specify timeouts of at least 240 seconds. Note that large deployments might need larger values.

    The default timeout is typically 50 or 60 seconds, which is not long enough to avoid **`409 Conflict`** or **`504 Gateway Timeout`** errors. The **`409 Conflict`** error can occur when the time needed to complete an operation is sufficiently long that a second request gets issued.

    For example, to specify 240 seconds when using HAProxy as a load balancer, set **`timeout client`** and **`timeout server`** to **`240000`**.

  - Ensure that the load balancer is configured to support the cipher **`TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`**.
    When the portal, as a client, calls back to platform-api-endpoint or consumer-api-endpoint of the management subsystem, it sends only a single cipher in the Client Hello. The cipher is **`TLS_ECDHE_RSA_WITH_AES256_GCM_SHA384 (0xc030)`**. The SSL Handshake will fail if this cipher is not configured (supported) on the client's load balancer.

```
# This sample HAProxy configuration file configures one HAProxy node to distribute traffic to
# Management, portal, analytics, and gateway clusters. Another option is to configure one HAproxy
# node per cluster.
```

- The following diagram depicts a typical layout for a load balancer in front of three API Connect subsystems, with each subsystem containing three Appliance/OVA nodes:

Multiple data center deployment strategies

Strategies for deploying API Connect on VMware across multiple data centers.

If you want to deploy API Connect across multiple data centers, then several options are available and are detailed in this topic.

Note:
You can install the subsystems that make up an API Connect deployment in different data centers, but it is not recommended to split a single API Connect subsystem across data centers. For example, if you are deploying a three replica analytics subsystem, then all analytics subsystem VMs (replicas) must run in the same data center. Splitting a three replica deployment across data centers is only supported when the network latency between the data centers is less than 10 ms.

For the gateway service, if TMS is required and an external OAuth provider cannot be used, then the gateways can be located in different data centers if network latency between data centers is less than 30 ms.

Remote gateway deployment

To provide high availability for your published APIs, you can deploy one or more gateway services in different data centers, and register them with the management subsystem in your main data center. If your main data center has an outage, then your remote gateways continue to process calls to your published APIs.

Remote gateway deployment is the simplest way to take advantage of multiple data centers. The main disadvantage is that you cannot update any published APIs during the main data center outage (because your management subsystem is in the main data center).

Cold-standby deployment

In a cold-standby deployment, API Connect is installed and running in your main data center. In your cold-standby data center, API Connect is ready to be installed and has access to the API Connect backup files from your main data center.

If your main data center has an outage, then you install API Connect in your cold-standby data center, and restore your most recent subsystem database backups to your cold-standby deployment.

Requirements for cold-standby configuration:

- The API Connect deployment in the cold-standby data center must use the same deployment profile as the main data center.
- The API Connect network endpoints that you define in your main data center must be valid in your cold-standby data center.
  For example, if the network endpoint for your Cloud Manager UI is `cloud-admin.apicinstall.example.com`, this endpoint must route correctly to the management subsystem you install in your cold-standby data center.

  Every network endpoint that you configure during API Connect installation and configuration in your main data center must be valid in your cold-standby data center.

- Ensure that subsystem backups are regularly copied from your main data center to your cold-standby. Backups must include both your project directory and your subsystem database backups. See Backing up and restoring on VMware.

The steps for failing over to your cold-standby data center are:

1. Install API Connect in your cold-standby data center.
2. Restore your API Connect subsystem database backups.
3. Update network routing so that user traffic is directed to your cold-standby data center.

Steps 1 and 2 are essentially the same as the disaster recovery steps to restore API Connect, see Management subsystem disaster recovery.

The advantage of the cold-standby deployment over the remote gateway deployment is that your full API Connect deployment is available in the cold-standby site. Management and portal subsystem users can update APIs and view analytics data while your main site is unavailable.

Warm-standby deployment

In the warm-standby deployment, the management and portal subsystems continually replicate their databases to a warm-standby API Connect deployment in a separate data center.

The advantage of the warm-standby deployment over cold-standby is that the failover process is faster, and the management and portal databases in the warm-standby site are fully up to date. With the cold-standby strategy, your management and portal databases are only as recent as the last backup you took from your main site.

The disadvantage of the warm-standby deployment is that it adds extra complexity to the API Connect installation process, and all ongoing maintenance procedures such as upgrade. Use the warm-standby deployment strategy only when the following are essential requirements:

- Minimal management and portal subsystem downtime.
- No management and portal data loss, when restoration of data from the last backup that was taken of your active site is not sufficient.

Requirements for warm-standby configuration:

- The API Connect deployment in the warm-standby data center must use the same deployment profile as the main data center.
- The API Connect network endpoints that you define in your main data center must be valid in your warm-standby data center.
  For example, if the network endpoint for your Cloud Manager UI is `cloud-admin.apicinstall.example.com`, this endpoint must route correctly to the management subsystem you install in your warm-standby data center.

  Every network endpoint that you configure during API Connect installation and configuration in your main data center must be valid in your warm-standby data center.

The warm-standby deployment configuration is referred to in this documentation as two data center disaster recovery (2DCDR). For more information about 2DCDR, see Two data center warm-standby deployment strategy on VMware.

- **Two data center warm-standby deployment strategy on VMware**
  An overview of the two data center disaster recovery deployment strategy in API Connect.

Two data center warm-standby deployment strategy on VMware

An overview of the two data center disaster recovery deployment strategy in API Connect.

The two data center disaster recovery warm-standby deployment configuration (referred to as 2DCDR) provides continuous replication of the management and portal subsystem databases to a warm-standby deployment in another data center.
Important: The 2DCDR deployment adds complexity to the API Connect installation procedures, and all subsequent maintenance procedures such as backup, restore, and upgrade. Before you decide to use the 2DCDR deployment strategy, review the Multiple data center deployment strategies to see whether any of the alternatives are better suited to your requirements.

Key points of the two data center disaster recovery (DR) solution

- Two data center DR is an active/warm-standby deployment for the management and portal subsystems, and must use manual failover.
- Two DataPower® Gateway subsystems must be deployed to provide high availability for the gateway service. However, this scenario doesn't provide high availability for the analytics service.
- If high availability is required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.
- Data consistency is prioritized over data availability.
- Latency between the two data centers must be less than 80 ms.
- Replication of the management database is asynchronous, so it is possible that the most recent updates do not transfer to the warm-standby data center if there is an active data center failure.
- Replication of the portal database is synchronous, and therefore the latency is limited to 80 ms or less.
- The management and the portal subsystems in the two data centers must use the same deployment profile.
- It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a two data center disaster recovery configuration.

Deployment architecture

A two data center deployment model is optimized for data consistency ahead of data availability, and must use manual failover when a fault occurs. For high availability of Management and Portal subsystems ensure that you use a three replica deployment profile. For more information on deployment profiles, see: Planning your deployment topology and profiles.

To achieve high availability for the DataPower Gateway, you must deploy two gateway subsystems. One subsystem in the active data center, and a separate subsystem in the warm-standby data center. Publish all Products and APIs to both gateway subsystems. The gateway subsystems are independent, and so are insulated if an issue

occurs in one of them. A global dynamic router can then be used to route traffic to one gateway subsystem or the other. If high availability is also required for the analytics service, two analytics subsystems must be configured, one per gateway subsystem, but with this configuration Developer Portal analytics isn't possible.

Dynamic routing
: Note: A dynamic routing device, such as a load balancer, is required to route traffic to either data center. However, neither this device nor its configuration is part of the API Connect offering. Contact IBM Services if you require assistance with configuring a dynamic router.
The dynamic router configuration must handle the traffic between the subsystems and between the data centers. For example, the consumer API calls from the portal subsystem to the management subsystem must transfer through a dynamic router so that the portal can use a single endpoint regardless of which data center the management subsystem is active in. The same is needed for calls to the Platform and Admin APIs from the other subsystems, as well as for incoming UI traffic for the portal UI, Cloud Manager UI, and API Manager UI.

  The dynamic router must support SSL passthrough, so that it routes the Mutual TLS (mTLS) connections between the management subsystem and the portal, and between the management subsystem and the DataPower Gateway. The router should not do TLS termination, it should do layer 4 based routing by using SNI.

  If you do not want to use mTLS between API Connect subsystems, you can Enable JWT security instead of mTLS.

Service status
: When a failure occurs, it is common practice to display an interstitial system outage web page. The dynamic router can be configured to display this web page when there is a failure, while the manual failover to the warm-standby data center is taking place.

Deployment profiles
: Both one replica and three replica deployment profiles can be used with two data center DR, but they must be the same at each data center. For more information about the deployment profiles, see VMware deployment overview and requirements.

For more information about a two data center DR deployment, see the following topics:

VMware

- Installing a two data center deployment
- Maintaining a two data center deployment (including information about normal operation data flows)
  - Backup and restore considerations for a two data center deployment
  - Upgrading a two data center deployment

Planning your analytics deployment

Plan your API Connect analytics deployment by reviewing options for topology, data modifications, and storage.

Deployment profile

The first decision that you must make is which **`deployment-profile`** you want to use. The available deployment profiles for analytics are: **`n1xc2.m16`**, **`n1xc4.m32`**, **`n1xc6.m48`**, **`n3xc4.m16`**, **`n3xc4.m32`**, **`n3xc6.m48`**, **`n3xc8.m64`**. For more information about deployment profiles, see Deployment profiles.

For a typical production deployment, choose a three replica profile. A one replica profile is only sufficient if you expect a low API transaction rate and do not plan to retain much analytics data.

Storage space

Based on your expected API transaction rate, you can estimate how much storage space your analytics subsystem requires. See Estimating storage requirements.

Firewall requirements

The analytics firewall requirements are documented here: Firewall requirments.

Inter-subsystem communication security

If your network infrastructure requires that load-balancers implement TLS termination, then mTLS between API Connect subsystems can be disabled and JSON Web Token (JWT) security can be used instead.
Note: Although mTLS is disabled, the network communication is still secured with standard TLS, which does not require passthrough to be enabled on load-balancers.
For more information about configuring JWT for network security, see: Enable JWT security.

Disabling internal storage

If you are offloading your analytics data to a third-party system, you can choose to not store your API event data in your API Connect analytics subsystem by disabling local analytics storage. With local storage disabled, the CPU, memory, and storage requirements of your analytics subsystem are greatly reduced, but you lose the ability to view your analytics data in the Analytics UIs.
Important: It is not possible to enable or disable local storage after installation.

API Connect TLS certificate best practices

Best practices for configuring and managing TLS certificates in an API Connect deployment on VMware.

API Connect generates TLS certificates during installation that are used to secure all network communication to, from, and within your API Connect deployment.

The TLS server certificates that secure the user-facing endpoints of your API Connect deployment can be replaced with your own organization's certificates. For example, if you want portal users to see your organization's certificate instead of the auto-generated API Connect certificate, you can update the certificate that secures the **portal-www** endpoint to use your own certificate.

If more than one endpoint is set to the same host, the certificates associated with the endpoints should be set to the same.

If you replace default certificates with your own certificates, then you are responsible for maintaining those certificates. They must meet the requirements defined in Table 1, and you must renew them before they expire.

The following table lists all the user-facing certificates in API Connect:

Table 1. User-facing endpoint certificates.

Certificate name	Description
portal-www-ingress	The **portal-www-ingress** certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites. The endpoint is called **portal-www** in the portal subsystem configuration.
api-manager-ui	The **api-manager-ui** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI. The endpoint in the management subsystem configuration uses the same name: **api-manager-ui**. The hostnames for which the certificate is valid must include the **api-manager-ui** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **serverAuth**.
cloud-admin-ui	The **cloud-admin-ui** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI. The endpoint in the management subsystem configuration uses the same name: **cloud-admin-ui**. The hostnames for which the certificate is valid must include the **cloud-admin-ui** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **serverAuth**.
consumer-api	The **consumer-api** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope. The endpoint in the management subsystem configuration uses the same name: **consumer-api** The hostnames for which the certificate is valid must include the **consumer-api** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **serverAuth**.
platform-api	The **platform-api** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope. The endpoint in the management subsystem configuration uses the same name: **platform-api** The hostnames for which the certificate is valid must include the **platform-api** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **serverAuth**.
hub	Used by the Automated API behavior testing application. User-facing ingress certificate for the **hub-endpoint**.

Note: The API invocation certificate (the certificate that is presented to callers of your APIs) is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.
Note: For more information about the non-user facing certificates used in API Connect, see TLS certificate concepts and operations

- **Customizing your user-facing certificates**
  How to set the user-facing endpoints of API Connect to use your own TLS server certificates.

Customizing your user-facing certificates

How to set the user-facing endpoints of API Connect to use your own TLS server certificates.

Before you begin

Identify the user-facing certificates that you want to customize: User-facing certificates.

Ensure that you have certificate, key, and CA PEM files for each certificate you want to customize. The PEM files must not be password-protected.

For example, to customize the certificate that secures the Cloud Manager UI, you must have the following PEM files: cloud-admin-ui-cert.pem, cloud-admin-ui-key.pem, cloud-admin-ui-ca.pem

User-facing certificates must meet the following requirements:

- Specify Extended Key Usage (EKU) of **serverAuth**.
- Include the Subject Alternative Name (SAN) of the endpoint that they secure.
- If the certificate is signed by an intermediate CA, then the ca.pem file must contain the full chain to root CA.

About this task

You update the user-facing certificates with the **apicup** command.

You can set custom user-facing certificates during installation, or you can update them after installation, replacing the default certificates that are generated.

Note: API Connect verifies certificates when you set them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your custom certificates before they expire.

Procedure

1. If you are updating a user-facing certificate after installation, you must first clear the default certificate that was created:

   ```
   apicup certs set <subsystem name> <certificate name> --clear
   ```

   For example, to clear the certificate that secures the Cloud Manager UI:

   ```
   apicup certs set mgmt cloud-admin-ui --clear
   ```

2. Set the user-facing certificate with the **apicup certs set** command, supplying the PEM files for your new certificate:

   ```
   apicup certs set <subsystem name> <certificate name> <cert file> <key_file> <ca file>
   ```

   For example:

   ```
   apicup certs set mgmt cloud-admin-ui cert.pem key.pem ca.pem
   ```

3. If you are updating the certificate after installation, then apply the update with `apicup subsys install`

   ```
   apicup subsys install <subsystem name>
   ```

4. You can verify that the certificate is updated with **apicup certs list --endpoints**:

   ```
   apicup certs list <subsystem name> --endpoints
   ```

   Example output:

   ```
   Common certificates
   ===================

   Name                        Summary                                                                Validation errors
   ----                        -------                                                                -----------------
   ...

   Subsystem def-management certificates
   =====================================

   Name                              Summary                                                          Validation errors
   ----                              -------                                                          -----------------
   ...
   cloud-admin-ui                    CN: cloud-admin-ui
                                     SubjectKeyId: 9E:8B:FA:7E:92:70:EC:86:2F:C3:3A:20:E8:13:EA:F4
                                     AuthorityKeyId: E4:AB:09:FF:A9:7D:D3:70:DD:AD:69:C4:A4:34:8D:96
   ...
   ```

   Note: Along with the user-facing certificates, the **apicup certs list** (without `--endpoints` flag) command outputs details of other internal API Connect certificates and secrets that you should not update.

If you see validation errors in **apicup certs list --endpoints** output, check Certificate validation reference.

If you want to revert to using automatically generated user-facing certificates, then you can clear and regenerate the certificates by following these steps:

1. Clear the certificate:

   ```
   apicup certs set <subsystem name> <certificate name> --clear
   ```

   Repeat for all certificates that you want to clear.
2. Generate new certificates for all the cleared certificates:

   ```
   apicup certs generate <subsystem name>
   ```

3. If you are updating the certificate after installation, then apply the update with `apicup subsys install`:

   ```
   apicup subsys install <subsystem name>
   ```

Installing API Connect

Use these instructions to install API Connect on VMware.

- **IBM API Connect Version 10 software product compatibility requirements**
  Ensure that your environment meets all the minimum operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.
- **VMware deployment overview and requirements**
  Review the requirements and considerations for deploying API Connect in a VMware environment.
- **API Connect licenses**
  When you install a new version of API Connect on VMware, you must accept a new license.
- **Preparing to install API Connect in VMware**
  Download the product files, setup the **apicup** command-line tool, create your API Connect project directory, and accept the API Connect licence.

- **Installing the management subsystem on VMware**
  Define the deployment configuration of your management subsystem, deploy the management OVA file, verify your management subsystem installation.
- **Installing the analytics subsystem on VMware**
  Define your analytics subsystem, create an ISO file for each analytics VM, and deploy the analytics VMs by using the analytics OVA file on a VMware virtual server.
- **Installing the developer portal subsystem on VMware**
  Define your portal subsystem, create an ISO file for each portal VM, and deploy the portal VMs by using the portal OVA file on a VMware virtual server.
- **Deploying DataPower Gateway virtual appliance**
  API Connect uses IBM DataPower® Gateway to provide the gateway service.

  How to install a two data center disaster recovery (2DCDR) deployment on VMware.

IBM API Connect Version 10 software product compatibility requirements

Ensure that your environment meets all the minimum operating system requirements. Use the IBM® Software Product Compatibility Reports site to generate a requirements report appropriate for your API Connect version and environment.

Generating a Software Product Compatibility Report

To generate an API Connect requirements report, complete the following steps:

1. Open the Detailed system requirements for a specific product page on the IBM Software Product Compatibility Reports site.
2. Search for the IBM API Connect product.
3. In the Search results list, select IBM API Connect.
4. From the Version list, select the required version.
5. Use the Filters to refine the contents of the requirements report.
6. Click Submit to generate your requirements report.

Important: When you review the report to determine your deployment needs, treat the stated CPU and memory requirements as reserved VMware capacity. For example, if the system requirements are 4 CPU and 16 GB RAM, then those resources must be available always from the underlying hardware and must not be coming from an over-committed pool of resources.

VMware deployment overview and requirements

Review the requirements and considerations for deploying API Connect in a VMware environment.

Overview of an API Connect deployment on VMware

An API Connect deployment on VMware consists of the following:

- A Linux, macOS, or Windows system from where the management, portal, and analytics subsystems are configured and managed. You create a directory on this system called the API Connect project directory. The project directory contains all the initial configuration of your management, portal, and analytics subsystems, the ISO files used to deploy them, and the TLS certificate chains to enable secure communication between them. A command-line tool called **apicup** is used to configure API Connect from your project directory.
- Management subsystem: Management VMs are deployed with the management OVA file. Three VMs for a three replica deployment. One VM for a one replica deployment.
- Portal subsystem: Portal VMs are deployed with the portal OVA file. Three VMs for a three replica deployment. One VM for a one replica deployment.
- Analytics subsystem: Analytics VMs are deployed with the analytics OVA file. Three VMs for a three replica deployment. One VM for a one replica deployment.
- Gateway subsystem: One or more DataPower Gateway appliances (physical or virtual). The DataPower Gateway is deployed following the DataPower documentation: https://www.ibm.com/docs/en/datapower-gateway. The gateways are not managed from the API Connect project directory.

In a VMware deployment, your API Connect VMs are also referred to as "appliances".

The API Connect software runs in docker containers that are managed in a Kubernetes environment that runs on the API Connect VMs. Most of the configuration of an API Connect VMware deployment is done in the project directory and the API Connect UIs, but some operations must be done inside the API Connect VMs, at the Kubernetes level.

Deployment requirements on VMware

- Review the compatibility requirements IBM API Connect Version 10 software product compatibility requirements
  Attention: API Connect is not supported on a FIPS-enabled environment.
- API Connect VMs require a CPU architecture that supports x86-64-v2.
- Do not change the hardware version of the OVA during installation. Do not attempt to use an unsupported version, even if VMware indicates compatibility with other versions. For example, when you deploy API Connect, the VMware UI might show information like:

Table 1.

Property	Value
Guest OS	`Ubuntu Linux (64-bit)`
Compatibility	`ESXi 5.5 and later (VM version 10)`
VMware Tools	`Yes`
CPUs	`4`

Property	Value
Memory	`16 GB`

Although the compatibility field shows **`ESXi 5.5 and later (VM version 10)`**, API Connect supports only the versions that are listed in IBM API Connect Version 10 software product compatibility requirements. Do not change the VM version of the OVA. The compatibility field value must remain at **`ESXi 5.5 and later (VM version 10)`**.

Attempts to modify the VMware compatibility might result in failure to boot the OVA, see https://kb.vmware.com/s/article/52683.

- For each subsystem VM, gather the following networking settings, which you must supply during initial configuration:

Table 2.

Network setting	Value for your system
IP address of the VM.	
Domain of the VM.	
IP addresses of the name servers (at least one DNS server is required).	
IP address of the network gateway (not DataPower® gateway) for the server.	
Name of the Ethernet interface.	
VLAN.	

Some virtualization environments require additional information when you create and configure virtual machines. For example, it might be necessary to assign a specific VLAN ID, resource pool, or datastore. Refer to information provided by your virtualization environment administrators.

Before you deploy your API Connect subsystem OVA files, you first define some API Connect configuration properties and create ISO files that contain these properties. The ISO files are used to provide the initial configuration to the API Connect subsystems when your deploy the OVA files.

You define your API Connect properties and create the ISO files in your project directory. You project directory system must have network access to where your API Connect OVAs are deployed. Requirements for the project directory system are:

- Linux, macOS, or Windows operating system.
- Your operating system must have one of the supported utilities for creating ISO files. The API Connect **apicup** tool uses **`mkisofs`** on Linux, and **`hdiutil`** on macOS. For Windows, you need software that creates ISO files by using **`mkisofs`**, such as CDRTools.
  Verify that the location of utility you use to create ISO files is included in the **`PATH`** environment variable for your operating system. When you create ISO files, if you encounter the message **`Error: unable to create config ISO for host`**, verify that you have sufficient permissions to run the command.
- Use a single project directory for all subsystems in your API Connect deployment, even if some subsystems are in a different VMware cluster.

Disk space requirements

For the management subsystem, the data disk requirement is 200 GB. The boot disk requires 100 GB, so the total minimum requirement is 300 GB.

The developer portal and analytics disk requirements vary with usage scenarios. See:

- Estimating storage requirements for analytics
- Developer portal hardware requirements

Key points for API Connect on VMware

- API Connect cannot be deployed on NFS.
- The time zone for API Connect VMs is set to Coordinated Universal Time. Do not change the time zone of your VMs.
- The time (not the time zone) on your project directory system and your VMware **`Host`** clock must match (within a few seconds).

  To verify the VMware host clock configuration, see https://kb.vmware.com/s/article/1003736. If a large time discrepancy exists between them, then the installation can fail due to invalid certificates.
- The API Connect VMs run a Kubernetes cluster that requires a dedicated IP range. These IP addresses cannot conflict with IP addresses used by other resources in your deployment, such as SMTP servers or user registries.

  The default values are **`172.16.0.0/16`** and **`172.17.0.0/16`**. If a **`/16`** subnet overlaps with existing IPs on the network, a CIDR as small as **`/22`** is acceptable.

  You cannot modify the IP ranges after installation.
- Only static IP addresses are supported. You cannot change IP addresses after installation.
- API Connect VM hostnames and endpoints must be all lowercase, and not contain any special characters except for "-".

  You cannot change hostnames or endpoints after installation. If you want to change the endpoints, then you must reinstall API Connect and follow the form factor migration steps.
- If you are installing with three replica deployment profiles, do not split the replicas (VMs) across multiple data centers, unless network latency between data centers is less than 10 ms. For more information about multiple data center deployment options, see Multiple data center deployment strategies.

Passwords and certificates

- Ensure that your project directory is secure. The apiconnect-up-v10.yml file in the project directory contains hashed and base64 encoded passwords.
- During initial configuration, you use the **`apicup`** command to specify an **ssh** keyfile that contains a public certificate for using **ssh** to log in to your API Connect VMs. Logging in with **ssh** key files is preferred because it is more secure than password-based login.
- Default certificates are generated for each subsystem unless certificates are explicitly set before deployment (using the `apicup certs set` command). See API Connect TLS certificate best practices.

Setting and using a hashed default password

During configuration of the management, analytics, and developer portal subsystems, you create a password to use to log in to the VMs console for the first time. You must use a password hashing utility to hash the password. You then use **apicup** to assign this hashed password to the subsystem. These configuration steps ensure that the password is not stored in plain text on the VMs data disk.

The syntax of the **apicup** command is:

```
apicup subsys set mgmt default-password='hashed_password'
```

Usage notes:

- The **default-password** is for the **apicadm** user account on the VM.
- The password for **apicadm** can be used **only** to log in through the VMware console. You cannot use it to **ssh** into the VM as an alternative to using the **ssh-keyfiles**. Interactive login for **ssh** is disabled.
- The **default-password** value configured is only used during initial installation (first boot) of each virtual appliance. Changing the value, then regenerating the ISO, and attaching the new ISO to the VM does not change the **apicadm** password.
- The **default-password** must be hashed. If it is plain text, you will not be able to log into the VM through the VMware console. When you use **apicup** to set or get **default-password**, **apicup** ensures that the hash type of the password is one of the following:
  - MD5
  - SHA1
  - SHA256
  - SHA512
  - BCRYPT
  - MD5-Crypt
- When using **apicup** to set a default password for a subsystem, be aware of syntax differences between operating systems. Windows requires double-quotes. Linux and macOS require single quotes.

Operating system	Command syntax
Linux or macOS	`apicup subsys set mgmt default-password='hashed_password'`
Windows	`apicup subsys set mgmt default-password="hashed_password"`

- You can use the **passwd** command (on the VM) to change the **apicadm** password.
- When using the VMware remote console to login to the appliance, be aware that the keyboard layout is US English. This can cause a problems with hashed passwords, if you created the ISO on a system with a different keyboard layout and you used special characters or symbols.

DataPower Gateway for API Connect on VMware

- Installation and configuration of DataPower Gateway on an appliance (physical or virtual) is completed after you install the management, analytics, and portal subsystems. For the gateway service in a VMware environment, use the instructions in Deploying DataPower Gateway virtual appliance.
- Ensure that DataPower Gateway firmware version you plan to install is compatible with the API Connect management subsystem version. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

API Connect licenses

When you install a new version of API Connect on VMware, you must accept a new license.

Setting the license ID on VMware

Each license has a unique identifier that is called a **License ID**. Use **apicup** to accept the license. License acceptance is stored in the **apiconnect-up-v10.yml** file.

```
apicup licenses accept <License ID>
```

For example:

```
apicup licenses accept L-HTFS-UAXYM3
```

- Use **apicup licenses list** to display licenses available. This command also shows all accepted licenses, including prior versions.
- If an invalid value is passed to **apicup licenses accept**, an error is displayed showing the valid values:

  ```
  Error: Must run `apicup licenses accept ID` with one of [L-GVEN-GFUPVE, L-BYRR-EEASJ3, .....]
  ```

- Until you accept the licence, all other **apicup** commands fail.

You accept the license during Preparing to install API Connect in VMware.

The licenses in Table 2 are used as the master mod-level license for all API Connect Fix Pack and security roll-up releases in this stream. There are no changes to license terms, only updates to open source notices documented in the notes for each.

Table 1. API Connect 10.0.8.1 and later licenses

License ID	Program Name	URL
L-HTFS-UAXYM3	IBM API Connect Enterprise V10.0.8.1+	https://ibm.biz/Bdan6M
L-FTGN-WUM5C5	IBM Cloud Pak for Integration - API Calls 16.1.0	https://ibm.biz/BdmPjg

Table 2. API Connect 10.0.8.0 licenses

License ID	Program Name	URL
L-DZZQ-MGVN8V	IBM API Connect Enterprise V10.0.8.0	https://ibm.biz/BdmPj8

License ID	Program Name	URL
L-FTGN-WUM5C5	IBM Cloud Pak for Integration - API Calls 16.1.0	https://ibm.biz/BdmPjg
L-EFSE-DEGF6Z	IBM API Connect Enterprise Add-on for IBM Products V10.0.8.0	https://ibm.biz/BdmPZB
L-QXKE-G3NZ57	IBM API Connect Professional V10.0.8.0	https://ibm.biz/BdmPZD

Preparing to install API Connect in VMware

Download the product files, setup the **apicup** command-line tool, create your API Connect project directory, and accept the API Connect licence.

Before you begin

Review VMware deployment overview and requirements.

About this task

In these first steps, you use the **apicup** command to create a project directory that contains the configuration file apiconnect-up-v10.yml. When you configure your subsystem API Connect using the **apicup** command, the configuration settings are saved in the apiconnect-up-v10.yml file.

All API Connect subsystems in your deployment must be configured from the same project directory.

Installation and configuration of DataPower® Gateway on an appliance (physical or virtual) is completed after you install the API Connect subsystems. For the gateway service in a VMware environment, use the instructions in Deploying DataPower Gateway virtual appliance.

Note:

- When maintaining API Connect, do not use **kubectl exec** commands to access API Connect pods unless advised by IBM.
- Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

Procedure

1. Obtain the API Connect installation files.
   The following files are used for initial deployment on VMware:

   IBM API Connect *<version>* Management for VMware
   : Management subsystem files

   IBM API Connect *<version>* Developer Portal for VMware
   : Developer Portal subsystem files

   IBM API Connect *<version>* Analytics for VMware
   : Analytics subsystem files

   IBM API Connect *<version>* Install Assist (apicup) for *<operating_system>*
   : The apicup installation utility. Required for all installations on VMware.

   IBM API Connect *<version>* Security Signature Bundle File
   : Signature files that you can use to verify the integrity of your downloads.

   IBM API Connect *<version>* Toolkit for *<operating_system>*
   : Toolkit command line utility. Packaged standalone, or with API Designer:
     - IBM API Connect *<version>* Toolkit for *<operating_system>*
     - IBM API Connect *<version>* Toolkit Designer for *<operating_system>*

     Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI. See Installing the toolkit.

   IBM API Connect *<version>* Local Test Environment
   : Optional test environment. See Testing an API with the Local Test Environment

2. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
3. Install the **apicup** command-line tool.
   a. Locate the apicup file, which you downloaded in step 1: "Install Assist (apicup) for *<operating_system>*"
   b. Rename the file to **apicup**.
   c. Linux® and macOS only: Make the apicup file an executable file by entering the following command:

      ```
      chmod +x apicup
      ```

   d. Set your path to the location of your apicup file.
      - For the OSX and Linux operating systems:

        ```
        export PATH=$PATH:/Users/your_path/
        ```

      - For the Windows operating system:

        ```
        set PATH=c:\your_path;%PATH%
        ```

4. Create a new directory from where you want to manage your API Connect deployment. This directory is referred to as your API Connect project directory.
   a. Create the project directory for your API Connect deployment:

      ```
      apicup init <apic project directory name>
      ```

      where *<apic project directory name>* is the name of the directory you want for this API Connect deployment.

      The command creates a new directory called *<apic project directory name>*, and an empty apiconnect-up-v10.yml file inside this directory.

Important: The project directory must be in a secure and permanent location. The files inside the project directory contain encoded password information and other information that is exposed in text format.

b. Copy the `apicup` executable into the project directory.

c. From within your project directory, specify the API Connect license:

```
apicup licenses accept <License ID>
```

The *<License ID>* is specific to the API Connect program name that you purchased. To view the supported license IDs, see API Connect licenses.

What to do next

Proceed to install each API Connect subsystem:

- Installing the management subsystem on VMware
- Installing the analytics subsystem on VMware
- Installing the developer portal subsystem on VMware
- Deploying DataPower Gateway virtual appliance

- **Verifying the integrity of IBM product files**
  You can verify the integrity of files to ensure that they originated from IBM and are not modified.

Verifying the integrity of IBM product files

You can verify the integrity of files to ensure that they originated from IBM and are not modified.

Before you begin

Import the public key so you can use it to verify files. You only need to import the public key once.

1. Install `gpg` (GNU Privacy Guard), available at https://www.gnupg.org/.

2. Create a file called PRD0003216key.pub.gpg and copy the following content into the file:

```
-----BEGIN PGP PUBLIC KEY BLOCK-----

=1Zs0
-----END PGP PUBLIC KEY BLOCK-----
```

3. Run the following command to import the public key to `gpg`:

```
gpg --import PRD0003216key.pub.gpg
```

For example:

```
$ gpg --import PRD0003216key.pub.gpg
gpg: key 020ED6B5DBE65F3B: public key "APIConnect <psirt@us.ibm.com>" imported
gpg: Total number processed: 1
gpg:               imported: 1
```

4. Run the following command to verify that the key was imported successfully:

```
gpg --list-key --fingerprint APIConnect
```

Make sure that the output of the command matches the following information:

```
$ gpg --list-key --fingerprint APIConnect
pub   rsa4096 2023-02-28 [SCE]
      39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
uid           [ unknown] APIConnect <psirt@us.ibm.com>
```

Procedure

Complete the following steps to verify product files for API Connect:

1. Visit IBM Fix Central and download the appropriate signatures_*<version>*.zip file for the version of API Connect that you will install or upgrade to. Extract the signatures_*<version>*.zip file to the folder containing the files that you want to verify.

2. Verify individual API Connect files to compare each file's signature with the fingerprint of the public key.
   To verify a file, run the following command:

   ```
   gpg --verify <file_to_verify>.asc
   ```

   For example, to verify helper_files.zip, ensure that it is stored in the same folder as the signatures file and run the following command:

   ```
   gpg --verify helper_files.zip.asc
   ```

   Example of a successful verification:

   ```
   $ gpg --verify helper_files.zip.asc
   gpg: assuming signed data in 'helper_files.zip'
   gpg: Signature made Mon 28 Sep 17:35:17 2020 PDT
   gpg:                using RSA key 39ED16345FCDEDB5D6EDE860020ED6B5DBE65F3B
   gpg: Good signature from "APIConnect <psirt@us.ibm.com>" [unknown]
   gpg: WARNING: This key is not certified with a trusted signature!
   gpg:          There is no indication that the signature belongs to the owner.
   Primary key fingerprint: 39ED 1634 5FCD EDB5 D6ED  E860 020E D6B5 DBE6 5F3B
   ```

   Example of a failed verification:

   ```
   gpg: assuming signed data in 'helper_files.zip'
   gpg: Signature made Tue 11 Jul 2023 09:28:02 PM PDT
   gpg:                using RSA key 39ED16345FCDEDB5D6EDE860020ED6B5DBE65F3B
   gpg: BAD signature from "APIConnect <psirt@us.ibm.com>" [unknown]
   ```

Installing the management subsystem on VMware

Define the deployment configuration of your management subsystem, deploy the management OVA file, verify your management subsystem installation.

- **Preparing the management subsystem for deployment**
  Specify configuration properties for your management subsystem, and create the deployment ISO file.
- **Deploying the management subsystem OVA**
  Deploy your management subsystem VMs with the installation OVA file and ISO files that you prepared.
- **Verifying the management subsystem installation**
  Verify that the deployment of the management subsystem VMs was successful, and configure scheduled backups.

Preparing the management subsystem for deployment

Specify configuration properties for your management subsystem, and create the deployment ISO file.

Before you begin

Review the Deployment requirements on VMware.

Complete the Preparing to install API Connect in VMware.

Procedure

1. Change to the project directory.

   ```
   cd <project directory>
   ```

2. Create your initial management subsystem definition.

   ```
   apicup subsys create <subsystem name> management
   ```

   Where *<subsystem name>* is the name you give the management subsystem that you are creating. The name must consist of lowercase alphanumeric characters or '-', contain no spaces, and starts and end with an a-z character.
   Verify that the new subsystem is created, and has empty or default properties set:

   ```
   apicup subsys get <subsystem name>
   ```

   The following output is returned:

   ```
   Appliance settings
   ==================

   Name                                Value           Description
   ----                                -----           ------
   additional-cloud-init-file                          (Optional) Path to additional cloud-init yml file
   ...
   <list of settings continues>
   ```

3. Specify the deployment profile for the subsystem, for example **n1xc4.m16**. The available profiles are described here: Planning your deployment topology and profiles.

```
apicup subsys set <subsystem name> deployment-profile=<profile>
```

Note: The deployment profiles that are shown in the `Description` column of the `apicup get` output might not be correct. The available profiles are documented in Planning your deployment topology and profiles.

4. Specify the API Connect license type.

```
apicup subsys set <subsystem name> license-use=<license type>
```

The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

5. Optional: Configure scheduled backups for your management database.
You can configure management database scheduled backups before or after installation. If you want to configure this now, follow step 1 of Configuring management database backups.

6. Optional: Configure your logging.
Logging can be configured after installation, but if you want to capture log events during installation then you must enable it before.
   a. Complete the procedure at Configuring remote logging for a VMware deployment.
   b. Enter the following command to create the log file:

```
apicup subsys set <subsystem name> additional-cloud-init-file=config_file.yml
```

7. Set your search domain. If you have multiple search domains, then use commas to separate them.

```
apicup subsys set <subsystem name> search-domain=<your search domain>
```

where *<your search domain>* is the domain for your VMs (use lowercase). For example: **myorganization.com**. Do not use wildcard DNS.

8. Set your domain name servers (DNS).
Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

```
apicup subsys set <subsystem name> dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
```

9. Set your management subsystem endpoints.

Table 1. Management subsystem endpoints

Setting	Endpoint host description
`platform-api`	Platform API endpoint. The host where your platform API calls are routed. `apicup subsys set <subsystem name> platform-api=platform-api.hostname.domain`
`consumer-api`	Consumer API endpoint. The host where your consumer API calls are routed. `apicup subsys set <subsystem name> consumer-api=consumer-api.hostname.domain`
`cloud-admin-ui`	Cloud Manager user interface API endpoint. The host where your cloud administrator user-interface API calls are routed. `apicup subsys set <subsystem name> cloud-admin-ui=cloud-admin-ui.hostname.domain`
`api-manager-ui`	API Manager user interface endpoint. The host where your API Manager API calls are routed. `apicup subsys set <subsystem name> api-manager-ui=api-manager-ui.hostname.domain`

10. Set the SSH public key to enable SSH public key authentication.
Specify the path to your SSH public key to enable SSH public key authentication. You can specify multiple paths by using commas as the separator.

```
apicup subsys set <subsystem name> ssh-keyfiles=<path to publicc ssh keyfile>
```

The public key is required so that the API Connect administrator can log in to the API Connect VMs with SSH. If you have multiple API Connect administrators, then include the public key for each administrator when you set **ssh-keyfiles**.

The default public key is typically located in the user's home directory, for example: **<home directory>/.ssh/id_rsa.pub**.

11. Set the VM console password.
   a. **Important**: Review the requirements for creating a hashed password. See Setting and using a hashed default password.
   b. Check that you have a password hashing tool installed.

Operating system	Command
Linux, macOS	If the **mkpasswd** command utility is not available, download and install it. (You can also use a different password hashing utility.) On macOS, use the command: `gem install mkpasswd`.
Windows, Red Hat	Use OpenSSL.

   c. Create a hashed password.

Operating system	Command
Ubuntu, Debian, macOS	`mkpasswd --method=sha-512 --rounds=4096 password`
Windows, Red Hat	For example, with OpenSSL: `openssl passwd -1 password`. You might need to add your password hashing utility to your path; for example on Windows: `set PATH=c:\cygwin64\bin;%PATH%`

   d. Set the hashed password for your subsystem:

```
apicup subsys set <subsystem name> default-password='<hashed password>'
```

- The password is hashed. If it is in plain text, you cannot log in to the VMware console.
- The password can be used only to log in through the VMware console. You cannot use it to SSH into the VM as an alternative to using the `ssh-keyfiles`.
- On Linux or macOS, use single quotation marks around *<hashed password>*. For Windows, use double quotation marks.
- If you are not using a US English keyboard, understand the limitations with using the remote VMware console. See VMware deployment overview and requirements.

12. Optional: If the default IP ranges of **172.16.0.0/16** and **172.17.0.0/16** (which are used by Kubernetes on your API Connect VMs) conflict with IP addresses that are used by other processes in your deployment, then you can set a smaller CIDR.
A CIDR as small as **/22** is supported.

    You can modify the IP ranges during initial installation only. You cannot modify them after the API Connect VMs are deployed. See Key points for API Connect on VMware.

    a. Update the IP range for the Kubernetes pods:

    ```
    apicup subsys set <subsystem name> k8s-pod-network='<new pod range>'
    ```

    where *<new pod range>* is the new value for the range.

    b. Update the IP range for Service networks:

    ```
    apicup subsys set <subsystem name> k8s-service-network='<new service range>'
    ```

    where *<new service range>* is the new value for the range.

13. Define the hostname for each subsystem VM that you are deploying. If you specified a one replica (n1) profile, then you are deploying one VM, so define one hostname. If you specified a three replica (n3) profile, then you are deploying three VMs so define three hostnames:

    ```
    apicup hosts create <subsystem name> <hostname.domainname> <hd password>
    ```

    where:
    - *<hostname.domainname>* is the fully qualified name for the subsystem VM.
    - *<hd password>* is the password that the Linux Unified Key Setup uses to encrypt the storage for your subsystem. This password is Base64 encoded when stored in your project directory, and is hashed in the ISO file and on the VM.

    Repeat this command for each subsystem VM in your deployment. For example, if you are deploying a one replica profile then run the command once, for a three replica profile run the command three times (once for each *<hostname.domainname>*).

14. Define the network interfaces and IP configuration for your subsystem VMs.

    ```
    apicup iface create <subsystem name> <hostname.domainname> <physical network id> <host ip address>/<subnet mask> <network gateway ip address>
    ```

    where *<physical network id>* is the network interface ID of your VM. The value is usually **ethx**, where ***x*** is a number from 0 to 9.

    Example:

    ```
    apicup iface create <subsystem name> <myHostname.domain> eth0 192.0.2.10/255.255.255.0 192.0.2.1
    ```

    For three replica deployments, repeat this command for each *<myHostname.domain>* in your subsystem deployment.

    Note: The *<network gateway ip address>* is the network gateway (not a DataPower Gateway). If you are creating multiple network interfaces (on each VM), each one must be on a different subnet with a different gateway.

15. Optional: Use **apicup** to view the configured hosts:

    ```
    apicup hosts list <subsystem name>
    testsrv0231.subnet1.example.com
        Device  IP/Mask                    Gateway
        eth0    1.2.152.231/255.255.254.0  1.2.152.1
    ```

    Note: This command might return the following messages, which you can ignore:

    ```
    * host is missing traffic interface
    * host is missing public interface
    ```

16. Define your NTP server.
    Note: If your environment has internet access, then **ntp.ubuntu.com** is used by default, and you can skip this step.

    a. Create a file called cloud-init.yaml and paste in the details of your NTP server.

    ```
    ntp:
      enabled: true
      ntp_client: systemd-timesyncd
      servers:
        - ntp.example.com
    ```

    b. Set **additional-cloud-init-file** to your cloud-init.yaml file.

    ```
    apicup subsys set <subsystem name> additional-cloud-init-file cloud-init.yaml
    ```

17. If you are installing a 2DCDR deployment, then follow the instructions in Installing a two data center deployment to configure your 2DCDR properties.
18. Verify that the configuration settings are valid.

    ```
    apicup subsys get <subsystem name> --validate
    ```

    The output shows all configuration settings, and has a checkmark against all settings that pass validation. If the setting does not have a checkmark, then it is invalid. See the following sample output.

    ```
    Appliance settings
    ==================

    Name                          Value

```

19. Create your ISO files.

    ```
    apicup subsys install <subsystem name> --out <subsystem name>plan-out
    ```

    The ISO files are created in the <project directory>/*<subsystem name>*plan-out directory.

    If the system cannot find your ISO file creation tool, then add it to your **PATH** property:

Operating system	Command
Linux, macOS	`export PATH=$PATH:/Users/your_path/`
Windows	`set PATH="c:\Program Files (x86)\cdrtools";%PATH%`

What to do next

Use the ISO files to deploy your management OVA files. See Deploying the management subsystem OVA.

Deploying the management subsystem OVA

Deploy your management subsystem VMs with the installation OVA file and ISO files that you prepared.

Before you begin

Complete the configuration and preparation of your management subsystem ISO files: Preparing the management subsystem for deployment.

About this task

If you using a three replica deployment profile, then repeat this task for each management VM in your management subsystem deployment.

Procedure

1. Log in to the VMware vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
    a. Select the Management subsystem OVA file template by navigating to the location where you downloaded the file in Preparing to install API Connect in VMware.
    b. Enter a name and location for your file.
    c. Select a resource for your template.
    d. Review the details for your template.
    e. Select the size of your configuration.
    f. Select the storage settings.
    Important: Select at least 200 GB for the data disk size. The boot disk needs 100 GB, so you need a total of 300 GB for the API Connect management subsystem.
    g. Select the networks.
    h. Customize the Template, if necessary.
    i. Review the details to ensure that they are correct.
    j. Select Finish to deploy the virtual machine.

    Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See VMware deployment overview and requirements.

    The template creation appears in your Recent Tasks list.
5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO files.
    a. Select the Navigate to the datastore file browser icon in the icon menu.
    b. Select the Upload a file to the Datastore icon in the icon menu.
    c. Navigate to the management ISO files that you created in Preparing the management subsystem for deployment.
    The API Connect ISO files are located in <project directory>/*<subsystem name>*plan-out
    d. Upload the ISO files to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
    a. On the Virtual Hardware tab, select CD/DVD Drive 1.
    b. For the Client Device, select Datastore ISO File.
    c. Find and select your datastore in the Datastores category.
    d. Find and select your ISO file in the Contents category.
    e. Select OK to commit your selection and exit the Select File window.
    f. Ensure that the Connect At Power On checkbox is selected.
    Tip:
        - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
    g. Select OK to commit your selection and close the window.
12. Start the virtual machine by selecting the play button on the icon bar.
    The installation might take several minutes to complete, depending on the availability of the system and the download speed.

What to do next

Verify your management subsystem installation: Verifying the management subsystem installation.

Verifying the management subsystem installation

Verify that the deployment of the management subsystem VMs was successful, and configure scheduled backups.

Before you begin

Complete the deployment of your management subsystem VMs: Deploying the management subsystem OVA.

Procedure

1. Log in to the API Connect VM by using SSH, and check the status of the installation:
    If you are using a three replica deployment profile, then repeat this step for each management VM in your management subsystem deployment.

    a. Enter the following command to connect to your management VM with SSH:

    ```
    ssh apicadm@<vm hostname>
    ```

    No password is required because you set your public key in step 10 of Preparing the management subsystem for deployment. If necessary, include the path to your SSH identity files:

    ```
    ssh -i <path to identity file> apicadm@<vm hostname>
    ```

    For example:

    ```
    ssh -i ~/.ssh/id_rsa apicadm@<vm hostname>
    ```

    b. Select Yes to continue connecting.
    Your hostnames are automatically added to your list of hosts.
    c. Run the **apic status** command to verify that the installation completed and that the system is running correctly.

```
sudo apic status
```

After installation completes, it can take several minutes for all servers to start. If you see the error message **Subsystems not running**, wait a few minutes, try the command again, and review the output in the **Status** column.

The status output for a correctly running management system is similar to the following:

```
apicadm@testsys0181:~$ sudo apic status
INFO[0000] Log level: info

2. Verify you can access the API Connect Cloud Manager UI at **`https://<hostname.domain>/admin`**.
   where *<hostname.domain>* is the **`cloud-admin-ui`** endpoint that you specified in Preparing the management subsystem for deployment.

   The first time that you access the Cloud Manager user interface, you enter `admin` for the username and `7iron-hide` for the password. You are prompted to change the Cloud Administrator password and email address. See Accessing the Cloud Manager user interface.

3. Take a backup of your project directory and configure scheduled management database backups. See Backing up and restoring the management subsystem.

Installing the analytics subsystem on VMware

Define your analytics subsystem, create an ISO file for each analytics VM, and deploy the analytics VMs by using the analytics OVA file on a VMware virtual server.

Before you begin

Review the Deployment requirements on VMware.

Complete the Preparing to install API Connect in VMware.

- **Preparing the analytics subsystem for deployment**
  Specify configuration properties for your analytics subsystem, and create the ISO files.
- **Deploying the analytics subsystem OVA**
  Deploy your analytics subsystem VMs with the installation OVA file and ISO files that you prepared.
- **Verifying installation of the analytics subsystem**
  Verify the deployment of the analytics subsystem and configure scheduled backups.

Preparing the analytics subsystem for deployment

Specify configuration properties for your analytics subsystem, and create the ISO files.

Before you begin

Review Planning your analytics deployment and decide on the following:

- Deployment profile for your analytics subsystem.
- Storage space requirement for your analytics data.
- If you want to offload analytics data to a third-party system and disable local storage, you must configure storage disablement before you create the deployment ISO files. See: Disable local storage.

Review the Deployment requirements on VMware.

Complete the Preparing to install API Connect in VMware.

Procedure

1. Change to the project directory.

   `cd <project directory>`

2. Create your initial analytics subsystem definition.

   ```
   apicup subsys create <subsystem name> analytics
   ```

   where *<subsystem name>* is the name you give the analytics subsystem that you are creating. The name must consist of lowercase alphanumeric characters or '-', contain no spaces, and starts and end with an a-z character.

   Verify that the new subsystem is created, and has empty or default properties set:

   ```
   apicup subsys get <subsystem name>
   ```

   The following output is returned:

   ```
   Appliance settings
   ==================

   Name                                Value           Description
   ----                                -----           ------
   additional-cloud-init-file                          (Optional) Path to additional cloud-init yml file
   ...
   <list of settings continues>
   ```

3. Specify the deployment profile for the subsystem, for example `n1xc4.m16`. The available profiles are described here: Planning your deployment topology and profiles.

   ```
   apicup subsys set <subsystem name> deployment-profile=<profile>
   ```

   Note: The deployment profiles that are shown in the `Description` column of the `apicup get` output might not be correct. The available profiles are documented in Planning your deployment topology and profiles.
4. Specify the API Connect license type.

   ```
   apicup subsys set <subsystem name> license-use=<license type>
   ```

   The *license_type* must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

5. Optional: Configure your logging.
   Logging can be configured after installation, but if you want to capture log events during installation then you must enable it before.
   a. Complete the procedure at Configuring remote logging for a VMware deployment.
   b. Enter the following command to create the log file:

      ```
      apicup subsys set <subsystem name> additional-cloud-init-file=config_file.yml
      ```

6. Set your ingestion endpoint.

   ```
   apicup subsys set <subsystem name> analytics-ingestion=unique_hostname.domain
   ```

   The ingestion endpoint must be set to the hostname of the analytics VM (one replica deployments only), or to the hostname of a load balancer configured in front of the analytics VMs. You use the ingestion endpoint when you register the analytics service in the Cloud Manager UI.
7. Set your search domain. If you have multiple search domains, then use commas to separate them.

   ```
   apicup subsys set <subsystem name> search-domain=<your search domain>
   ```

   where *<your search domain>* is the domain for your VMs (use lowercase). For example: `myorganization.com`. Do not use wildcard DNS.

8. Set your domain name servers (DNS).
   Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

   ```
   apicup subsys set <subsystem name> dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
   ```

9. Set the SSH public key to enable SSH public key authentication.
   Specify the path to your SSH public key to enable SSH public key authentication. You can specify multiple paths by using commas as the separator.

   ```
   apicup subsys set <subsystem name> ssh-keyfiles=<path to publicc ssh keyfile>
   ```

   The public key is required so that the API Connect administrator can log in to the API Connect VMs with SSH. If you have multiple API Connect administrators, then include the public key for each administrator when you set `ssh-keyfiles`.

   The default public key is typically located in the user's home directory, for example: `<home directory>/.ssh/id_rsa.pub`.

10. Set the VM console password.
    a. **Important**: Review the requirements for creating a hashed password. See Setting and using a hashed default password.
    b. Check that you have a password hashing tool installed.

Operating system	Command
Linux, macOS	If the **mkpasswd** command utility is not available, download and install it. (You can also use a different password hashing utility.) On macOS, use the command: `gem install mkpasswd`.
Windows, Red Hat	Use OpenSSL.

    c. Create a hashed password.

Operating system	Command
Ubuntu, Debian, macOS	`mkpasswd --method=sha-512 --rounds=4096 password`
Windows, Red Hat	For example, with OpenSSL: `openssl passwd -1 password`. You might need to add your password hashing utility to your path; for example on Windows: `set PATH=c:\cygwin64\bin;%PATH%`

    d. Set the hashed password for your subsystem:

```
apicup subsys set <subsystem name> default-password='<hashed password>'
```

- The password is hashed. If it is in plain text, you cannot log in to the VMware console.
- The password can be used only to log in through the VMware console. You cannot use it to SSH into the VM as an alternative to using the **ssh-keyfiles**.
- On Linux or macOS, use single quotation marks around *<hashed password>*. For Windows, use double quotation marks.
- If you are not using a US English keyboard, understand the limitations with using the remote VMware console. See VMware deployment overview and requirements.

11. Optional: If the default IP ranges of **172.16.0.0/16** and **172.17.0.0/16** (which are used by Kubernetes on your API Connect VMs) conflict with IP addresses that are used by other processes in your deployment, then you can set a smaller CIDR.
A CIDR as small as **/22** is supported.

    You can modify the IP ranges during initial installation only. You cannot modify them after the API Connect VMs are deployed. See Key points for API Connect on VMware.

    a. Update the IP range for the Kubernetes pods:

    ```
    apicup subsys set <subsystem name> k8s-pod-network='<new pod range>'
    ```

    where *<new pod range>* is the new value for the range.

    b. Update the IP range for Service networks:

    ```
    apicup subsys set <subsystem name> k8s-service-network='<new service range>'
    ```

    where *<new service range>* is the new value for the range.

12. Define the hostname for each subsystem VM that you are deploying. If you specified a one replica (n1) profile, then you are deploying one VM, so define one hostname. If you specified a three replica (n3) profile, then you are deploying three VMs so define three hostnames:

    ```
    apicup hosts create <subsystem name> <hostname.domainname> <hd password>
    ```

    where:
    - *<hostname.domainname>* is the fully qualified name for the subsystem VM.
    - *<hd password>* is the password that the Linux Unified Key Setup uses to encrypt the storage for your subsystem. This password is Base64 encoded when stored in your project directory, and is hashed in the ISO file and on the VM.

    Repeat this command for each subsystem VM in your deployment. For example, if you are deploying a one replica profile then run the command once, for a three replica profile run the command three times (once for each *<hostname.domainname>*).

13. Define the network interfaces and IP configuration for your subsystem VMs.

    ```
    apicup iface create <subsystem name> <hostname.domainname> <physical network id> <host ip address>/<subnet mask> <network gateway ip address>
    ```

    where *<physical network id>* is the network interface ID of your VM. The value is usually **eth*x***, where ***x*** is a number from 0 to 9.

    Example:

    ```
    apicup iface create <subsystem name> <myHostname.domain> eth0 192.0.2.10/255.255.255.0 192.0.2.1
    ```

    For three replica deployments, repeat this command for each *<myHostname.domain>* in your subsystem deployment.

    Note: The *<network gateway ip address>* is the network gateway (not a DataPower Gateway). If you are creating multiple network interfaces (on each VM), each one must be on a different subnet with a different gateway.

14. Optional: Use **apicup** to view the configured hosts:

    ```
    apicup hosts list <subsystem name>
    testsrv0231.subnet1.example.com
        Device  IP/Mask                    Gateway
        eth0    1.2.152.231/255.255.254.0  1.2.152.1
    ```

    Note: This command might return the following messages, which you can ignore:

    ```
    * host is missing traffic interface
    * host is missing public interface
    ```

15. Optional: Enable JWT security instead of mTLS for communication from management and gateway to your analytics subsystem.
JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.
To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

    ```
    apicup subsys get <management subsystem name>

    ...
    jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to validate JWT -- this is unsettable and is generated based on the platform-api endpoint
    ...
    ```

    Disable mTLS and enable JWT by setting the jwks-url with **apicup** on your analytics subsystem:

    ```
    apicup subsys set <analytics subsystem name> mtls-validate-client=false
    apicup subsys set <analytics subsystem name> jwks-url=https://appliance1.apic.acme.com/api/cloud/oauth2/certs
    ```

    Note: Do not disable mTLS without enabling JWT.
    JWT for gateway to analytics communication requires an additional step during gateway registration. Enable the Use JWT switch when you register the gateway in the Cloud Manager UI.

16. If you configured additional deployment options in an extra-values file, run the following command to make the file available during installation:

    ```
    apicup subsys set <subsystem name> extra-values-file <path to analytics-extra-values.yaml>
    ```

17. Define your NTP server.
    Note: If your environment has internet access, then `ntp.ubuntu.com` is used by default, and you can skip this step.
    a. Create a file called cloud-init.yaml and paste in the details of your NTP server.

```
ntp:
  enabled: true
  ntp_client: systemd-timesyncd
  servers:
    - ntp.example.com
```

    b. Set `additional-cloud-init-file` to your cloud-init.yaml file.

```
apicup subsys set <subsystem name> additional-cloud-init-file cloud-init.yaml
```

18. Verify that the configuration settings are valid.

```
apicup subsys get <subsystem name> --validate
```

    The output shows all configuration settings, and has a checkmark against all settings that pass validation. If the setting does not have a checkmark, then it is invalid. See the following sample output.

```
 apicup subsys get analyt --validate
Appliance settings
==================

```

19. Create your ISO files.

```
apicup subsys install <subsystem name> --out <subsystem name>plan-out
```

    The ISO files are created in the <project directory>/<*subsystem name*>plan-out directory.

    If the system cannot find your ISO file creation tool, then add it to your `PATH` property:

Operating system	Command
Linux, macOS	`export PATH=$PATH:/Users/your_path/`
Windows	`set PATH="c:\Program Files (x86)\cdrtools";%PATH%`

What to do next

Deploy you analytics subsystem VMs: Deploying the analytics subsystem OVA.

Deploying the analytics subsystem OVA

Deploy your analytics subsystem VMs with the installation OVA file and ISO files that you prepared.

Before you begin

Complete the configuration and preparation of your analytics subsystem ISO files: Preparing the analytics subsystem for deployment.

About this task

Repeat this procedure for each analytics VM that you are deploying. Use the ISO files created in Preparing the analytics subsystem for deployment.

Procedure

1. Log in to the VMware vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
   a. Select the analytics subsystem OVA file template by navigating to the location where you downloaded the file in Preparing to install API Connect in VMware.
   b. Enter a name and location for your file.
   c. Select a resource for your template.
   d. Review the details for your template.
   e. Select the size of your configuration.
   f. Select the storage settings.
      Note: Specify a storage size large enough for your estimated analytics data usage: Estimating storage requirements. If in doubt, set the size to 500 GB.
   g. Select the networks.
   h. Customize the Template, if necessary.
   i. Review the details to ensure that they are correct.
   j. Select Finish to deploy the virtual machine.

   Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See VMware deployment overview and requirements.

   The template creation appears in your Recent Tasks list.
5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO files.
   a. Select the Navigate to the datastore file browser icon in the icon menu.
   b. Select the Upload a file to the Datastore icon in the icon menu.
   c. Navigate to the analytics ISO files that you created in Preparing the analytics subsystem for deployment.
      The API Connect ISO files are located in <project directory>/<*subsystem name*>plan-out
   d. Upload the ISO files to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
    a. On the Virtual Hardware tab, select CD/DVD Drive 1.
    b. For the Client Device, select Datastore ISO File.
    c. Find and select your datastore in the Datastores category.
    d. Find and select your ISO file in the Contents category.
    e. Select OK to commit your selection and exit the Select File window.
    f. Ensure that the Connect At Power On checkbox is selected.
       Tip:
       - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
    g. Select OK to commit your selection and close the window.
12. Start the virtual machine by selecting the play button on the icon bar.
    The installation might take several minutes to complete, depending on the availability of the system and the download speed.

What to do next

Verify your deployed analytics VMs: Verifying installation of the analytics subsystem

Verifying installation of the analytics subsystem

Verify the deployment of the analytics subsystem and configure scheduled backups.

Before you begin

Complete Deploying the analytics subsystem OVA.

Procedure

1. Log in to the API Connect VM by using SSH, and check the status of the installation:
   If you are using a three replica deployment profile, then repeat this step for each VM in your analytics subsystem deployment.

   a. Enter the following command to connect to your analytics VM with SSH:

   ```
   ssh apicadm@<vm hostname>
   ```

No password is required because you set your public key in step 9 on Preparing the analytics subsystem for deployment. If necessary, include the path to your SSH identity files:

```
ssh -i <path to identity file> apicadm@<vm hostname>
```

For example:

```
ssh -i ~/.ssh/id_rsa apicadm@<vm hostname>
```

b. Select Yes to continue connecting.
Your hostnames are automatically added to your list of hosts.
c. Run the **apic status** command to verify that the installation completed and that the system is running correctly.
The command output for a correctly running analytics system is similar to the following:

```
#sudo apic status

```

2. If you have installed all the API Connect subsystems, then continue to Post-deployment steps.
3. Configure backups of the subsystem. Follow the instructions in Backing up and restoring the analytics subsystem.

Installing the developer portal subsystem on VMware

Define your portal subsystem, create an ISO file for each portal VM, and deploy the portal VMs by using the portal OVA file on a VMware virtual server.

Before you begin

Review the Deployment requirements on VMware.

Complete Preparing to install API Connect in VMware.

- **Preparing the portal subsystem for deployment**
  Specify configuration properties for your developer portal subsystem, and create the ISO files.
- **Deploying the portal subsystem OVA**
  Deploy your portal subsystem VMs with the installation OVA file and ISO files that you prepared.
- **Verifying installation of the portal subsystem**
  Verify that the portal subsystem installation succeeded.
- **Defining multiple portal endpoints for a VMware environment**
  Multiple public facing endpoints (`portal-www`) can be defined for the portal subsystem.

Preparing the portal subsystem for deployment

Specify configuration properties for your developer portal subsystem, and create the ISO files.

Before you begin

Review the Deployment requirements on VMware.

Complete Preparing to install API Connect in VMware.

Procedure

1. Change to the project directory.

   ```
   cd <project directory>
   ```

2. Create your initial portal subsystem definition.

   ```
   apicup subsys create <subsystem name> portal
   ```

   where *<subsystem name>* is the name you give the portal subsystem that you are creating. The name must consist of lowercase alphanumeric characters or '-', contain no spaces, and starts and end with an a-z character.

   Verify that the new subsystem is created, and has empty or default properties set:

   ```
   apicup subsys get <subsystem name>
   ```

   The following output is returned:

   ```
   Appliance settings
   ==================

   Name                                  Value           Description
   ----                                  -----           ------
   additional-cloud-init-file                            (Optional) Path to additional cloud-init yml file
   ...
   <list of settings continues>
   ```

3. Specify the deployment profile for the subsystem, for example `n1xc4.m16`. The available profiles are described here: Planning your deployment topology and profiles.

   ```
   apicup subsys set <subsystem name> deployment-profile=<profile>
   ```

   Note: The deployment profiles that are shown in the `Description` column of the `apicup get` output might not be correct. The available profiles are documented in Planning your deployment topology and profiles.

4. Specify the API Connect license type.

   ```
   apicup subsys set <subsystem name> license-use=<license type>
   ```

   The *license_type* must be either `production` or `nonproduction`. If not specified, the default value is `nonproduction`.

5. Optional: Configure scheduled backups of the portal database.
   Refer to the instructions in Backing up and restoring the portal subsystem.

6. Optional: Configure your logging.
   Logging can be configured after installation, but if you want to capture log events during installation then you must enable it before.
   a. Complete the procedure at Configuring remote logging for a VMware deployment.
   b. Enter the following command to create the log file:

      ```
      apicup subsys set <subsystem name> additional-cloud-init-file=config_file.yml
      ```

7. Set your portal endpoints.
   The endpoints must be unique hostnames which both point to the IP address of the portal VM (single node deployment), or to the IP of a load balancer configured in front of the portal VMs.

Setting	Endpoint host description

Setting	Endpoint host description
portal-admin	This is the *unique_hostname* for communication between your management subsystem and portal. The values for the portal-admin and portal-www must be different. `apicup subsys set <subsystem name> portal-admin=<unique_hostname.domain>`
portal-www	This is the *unique_hostname* to be used for your developer portal sites. Multiple `portal-www` endpoints can be configured, as described here: Defining multiple portal endpoints for a VMware environment. `apicup subsys set <subsystem name> portal-www=<unique_hostname.domain>`

8. Set your search domain. If you have multiple search domains, then use commas to separate them.

   ```
   apicup subsys set <subsystem name> search-domain=<your search domain>
   ```

   where *<your search domain>* is the domain for your VMs (use lowercase). For example: `myorganization.com`. Do not use wildcard DNS.

9. Set your domain name servers (DNS).
   Supply the IP addresses of the DNS servers for your network. Use a comma to separate multiple server addresses.

   ```
   apicup subsys set <subsystem name> dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
   ```

10. Set the SSH public key to enable SSH public key authentication.
    Specify the path to your SSH public key to enable SSH public key authentication. You can specify multiple paths by using commas as the separator.

    ```
    apicup subsys set <subsystem name> ssh-keyfiles=<path to publicc ssh keyfile>
    ```

    The public key is required so that the API Connect administrator can log in to the API Connect VMs with SSH. If you have multiple API Connect administrators, then include the public key for each administrator when you set `ssh-keyfiles`.

    The default public key is typically located in the user's home directory, for example: `<home directory>/.ssh/id_rsa.pub`.

11. If there are multiple management subsystems in the same project, set the portal subsystem's `platform-api` and `consumer-api` certificates to match those used by the appropriate management subsystem to ensure that the portal subsystem is correctly associated with that management subsystem.
    This step applies only if you defined one or more management subsystems in your project directory.

    A portal subsystem can be associated with only one management subsystem. To associate the new portal subsystem with the appropriate management subsystem, manually set the `mgmt-platform-api` and `mgmt-consumer-api` certificates to match the ones used by the management subsystem.

    a. Run the following commands to get the certificates from the management subsystem:

    ```
    apicup certs get <management subsystem name> platform-api -t cert > platform-api.crt
    apicup certs get <management subsystem name> platform-api -t key > platform-api.key
    apicup certs get <management subsystem name> platform-api -t ca > platform-api-ca.crt

    apicup certs get <management subsystem name> consumer-api -t cert > consumer-api.crt
    apicup certs get <management subsystem name> consumer-api -t key > consumer-api.key
    apicup certs get <management subsystem name> consumer-api -t ca > consumer-api-ca.crt
    ```

    where *`mgmt-subsystem-name`* is the name of the specific management subsystem that you want to associate the new portal subsystem with.

    b. Run the following commands to set the portal's certificates to match those used by the management subsystem:

    ```
    apicup certs set <portal subsystem name> mgmt-platform-api Cert_file_path Key_file_path CA_file_path

    apicup certs set <portal subsystem name> mgmt-consumer-api Cert_file_path Key_file_path CA_file_path
    ```

12. Set the VM console password.
    a. **Important**: Review the requirements for creating a hashed password. See Setting and using a hashed default password.
    b. Check that you have a password hashing tool installed.

Operating system	Command
Linux, macOS	If the **mkpasswd** command utility is not available, download and install it. (You can also use a different password hashing utility.) On macOS, use the command: `gem install mkpasswd`.
Windows, Red Hat	Use OpenSSL.

    c. Create a hashed password.

Operating system	Command
Ubuntu, Debian, macOS	`mkpasswd --method=sha-512 --rounds=4096 password`
Windows, Red Hat	For example, with OpenSSL: `openssl passwd -1 password`. You might need to add your password hashing utility to your path; for example on Windows: `set PATH=c:\cygwin64\bin;%PATH%`

    d. Set the hashed password for your subsystem:

    ```
    apicup subsys set <subsystem name> default-password='<hashed password>'
    ```

    - The password is hashed. If it is in plain text, you cannot log in to the VMware console.
    - The password can be used only to log in through the VMware console. You cannot use it to SSH into the VM as an alternative to using the `ssh-keyfiles`.
    - On Linux or macOS, use single quotation marks around *<hashed password>*. For Windows, use double quotation marks.
    - If you are not using a US English keyboard, understand the limitations with using the remote VMware console. See VMware deployment overview and requirements.

13. Optional: If the default IP ranges of `172.16.0.0/16` and `172.17.0.0/16` (which are used by Kubernetes on your API Connect VMs) conflict with IP addresses that are used by other processes in your deployment, then you can set a smaller CIDR.

A CIDR as small as **/22** is supported.

You can modify the IP ranges during initial installation only. You cannot modify them after the API Connect VMs are deployed. See Key points for API Connect on VMware.

a. Update the IP range for the Kubernetes pods:

```
apicup subsys set <subsystem name> k8s-pod-network='<new pod range>'
```

where *<new pod range>* is the new value for the range.

b. Update the IP range for Service networks:

```
apicup subsys set <subsystem name> k8s-service-network='<new service range>'
```

where *<new service range>* is the new value for the range.

14. Define the hostname for each subsystem VM that you are deploying. If you specified a one replica (n1) profile, then you are deploying one VM, so define one hostname. If you specified a three replica (n3) profile, then you are deploying three VMs so define three hostnames:

```
apicup hosts create <subsystem name> <hostname.domainname> <hd password>
```

where:

- *<hostname.domainname>* is the fully qualified name for the subsystem VM.
- *<hd password>* is the password that the Linux Unified Key Setup uses to encrypt the storage for your subsystem. This password is Base64 encoded when stored in your project directory, and is hashed in the ISO file and on the VM.

Repeat this command for each subsystem VM in your deployment. For example, if you are deploying a one replica profile then run the command once, for a three replica profile run the command three times (once for each *<hostname.domainname>*).

15. Define the network interfaces and IP configuration for your subsystem VMs.

```
apicup iface create <subsystem name> <hostname.domainname> <physical network id> <host ip address>/<subnet mask> <network gateway ip address>
```

where *<physical network id>* is the network interface ID of your VM. The value is usually **ethx**, where ***x*** is a number from 0 to 9.

Example:

```
apicup iface create <subsystem name> <myHostname.domain> eth0 192.0.2.10/255.255.255.0 192.0.2.1
```

For three replica deployments, repeat this command for each *<myHostname.domain>* in your subsystem deployment.

Note: The *<network gateway ip address>* is the network gateway (not a DataPower Gateway). If you are creating multiple network interfaces (on each VM), each one must be on a different subnet with a different gateway.
Note: You can optionally configure a second network interface (NIC) card for use with portal. In this scenario, one NIC is used for internal traffic between the portal and management subsystems, and the second is used as a public interface. If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway. For information on configuring two NICs for portal, see Configuring two NICs on the portal.

16. Optional: You can specify a range of allowable client IP addresses.
Create a file called **ptl-extra-values.yaml**, and paste in the following contents:

```
  spec:
    portalUIEndpoint:
        annotations:
          ingress.kubernetes.io/whitelist-source-range: 1.2.88.0/24
```

In this example, **1.2.88.0/24** is the acceptable range of client IP addresses.

You can optionally restrict which IP addresses can access any of the ingresses by creating an allowlist annotation, which allows only the specified IP addresses to access the ingress and denies all other source IP addresses. See Specifying a range of allowable client IP addresses for the portal.

Note: One usage of this restriction is the scenario where you split traffic between your private and public networks in 2 NIC configuration.

17. Optional: Use **apicup** to view the configured hosts:

```
apicup hosts list <subsystem name>
testsrv0231.subnet1.example.com
    Device  IP/Mask                    Gateway
    eth0    1.2.152.231/255.255.254.0  1.2.152.1
```

Note: This command might return the following messages, which you can ignore:

```
* host is missing traffic interface
* host is missing public interface
```

18. Optional: Enable JWT security instead of mTLS for communication from management to your portal subsystem.
JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS. To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

```
apicup subsys get <management subsystem name>

...
jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```

Disable mTLS and enable JWT by setting the jwks-url with **apicup** on your analytics subsystem:

```
apicup subsys set <subsystem name> mtls-validate-client=false
apicup subsys set <subsystem name> jwks-url=https://appliance1.apic.acme.com/api/cloud/oauth2/certs
```

Note: Do not disable mTLS without enabling JWT.

19. Define your NTP server.

Note: If your environment has internet access, then **ntp.ubuntu.com** is used by default, and you can skip this step.

a. Create a file called cloud-init.yaml and paste in the details of your NTP server.

```
ntp:
  enabled: true
  ntp_client: systemd-timesyncd
  servers:
    - ntp.example.com
```

b. Set **additional-cloud-init-file** to your cloud-init.yaml file.

```
apicup subsys set <subsystem name> additional-cloud-init-file cloud-init.yaml
```

20. If you are installing a 2DCDR deployment, then follow the instructions in Installing a two data center deployment to configure your 2DCDR properties.
21. Verify that the configuration settings are valid.

```
apicup subsys get <subsystem name> --validate
```

The output shows all configuration settings, and has a checkmark against all settings that pass validation. If the setting does not have a checkmark, then it is invalid. See the following sample output.

```
Appliance settings
==================

Name                          Value

22. Create your ISO files.

```
apicup subsys install <subsystem name> --out <subsystem name>plan-out
```

The ISO files are created in the <project directory>/<*subsystem name*>plan-out directory.

If the system cannot find your ISO file creation tool, then add it to your **PATH** property:

Operating system	Command
Linux, macOS	`export PATH=$PATH:/Users/your_path/`

Operating system	Command
Windows	`set PATH="c:\Program Files (x86)\cdrtools";%PATH%`

What to do next

Deploy your portal subsystems: Deploying the portal subsystem OVA.

- **Configuring two NICs on the portal**
  Configure the portal to use two network interface cards.

Configuring two NICs on the portal

Configure the portal to use two network interface cards.

About this task

When deploying the portal, you can optionally separate network traffic such that the portal has a network interface in your private network, where the communications to the management subsystem take place, and another network interface in your public network, where the end users can access the portal web sites.

You can do this by using the iface on eth0 for your traffic and defining an extra iface definition (eth1) for your public interface. Do this as part of the initial configuration of the portal. Note the following requirements:

- iface eth0 and eth1 must have different subnets. This means that you cannot test the configuration by using two IP addresses on the same subnet, due to the routing table produced by the VM when it boots.
- The hostname of the machine must be reachable via eth0 and you must use eth0 as the traffic (private interface) and eth1 as the public interface.

Procedure

1. Verify that you have created a first interface, by following the instructions in Step 13 of Configuring the Developer Portal subsystem.
2. Use `apicup` to add an extra iface definition as follows for your public interface:

   ```
   apicup iface create <subsystem name> test0094.test.example.com eth1 1.2.3.232/255.255.254.0 1.2.3.1
   ```

3. Set the hostname of your portal-www ingress to the hostname that is associated with the IP address given on `eth1`.

   ```
   apicup subsys set <subsystem name> portal-www portal.myhost0232.company.com
   ```

4. When configuring the second NIC during initial installation, return to Step 14 of Configuring the Developer Portal subsystem. Follow the remaining steps in the configuration instructions, and then create the portal OVA and deploy it as usual.
   Notes:
   - If you are creating multiple network interfaces, each one must be on a different subnet with a different gateway.
   - Before powering on the portal, use the VMware GUI to add a second network card to the VM, with the correct settings for your public network.

Deploying the portal subsystem OVA

Deploy your portal subsystem VMs with the installation OVA file and ISO files that you prepared.

Before you begin

Complete Preparing the portal subsystem for deployment.

About this task

If you are using a three replica deployment profile, then repeat this task for each portal VM in your portal subsystem deployment.

Procedure

1. Log in to the VMware vSphere Web Client.
2. Using the VSphere Navigator, navigate to the directory where you are deploying the OVA file.
3. Right-click the directory and select Deploy OVF Template.
4. Complete the Deploy OVF Template wizard.
   a. Select the portal subsystem OVA file template by navigating to the location where you downloaded the file in Preparing to install API Connect in VMware.
   b. Enter a name and location for your file.
   c. Select a resource for your template.
   d. Review the details for your template.
   e. Select the size of your configuration.
   f. Select the storage settings.
   The number of CPUs, RAM, and disk space that you need for the portal varies depending on the number of sites that are hosted and the number of concurrent users you expect your sites to have:

Table 1. Developer Portal hardware requirements

Number of sites	Number of concurrent users	Number of CPUs	Amount of RAM (GB)	Data Disk Size (GB)++
1	1	2**	4	50
20	5	4	16	70
100	20	8	32	100
100	100	16	64	500

Important:

- ++The data disk size is extra to the main disk of the OVA. The main disk of the OVA is sized at 100 GB, and should not be changed. Therefore, the total disk size of the OVA is 100 GB plus the data disk size. The default data disk size is 200 GB. If you want to select a different value, then you need to do this by using the OVF Tool, or the VMware GUI, before you power on the VM. Certain versions of the VMware GUI do not allow you to resize the data disk, and in this case use the OVF Tool.
- **The requirement of 2 CPUs is suitable only for proof-of-concept work, and non-high availability deployments. For example, this configuration is suitable for the demo mode of the apicup installation, which is set by using the command `apicup subsys set <subsystem name> deployment-profile=n1xc2.m8`.
- It is not recommended to have more than 100 sites per portal subsystem. It is not necessary to have a portal site for every catalog, for example catalogs that are only for API developers don't need a portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure more portal subsystems; see Registering a Portal service.

g. Select the networks.
h. Customize the Template, if necessary.
i. Review the details to ensure that they are correct.
j. Select Finish to deploy the virtual machine.

Note: Do not change the OVA hardware version, even if the VMware UI shows a Compatibility range that includes other versions. See VMware deployment overview and requirements.

The template creation appears in your Recent Tasks list.

5. Select the Storage tab in the Navigator.
6. Navigate to your datastore.
7. Upload your ISO files.
   a. Select the Navigate to the datastore file browser icon in the icon menu.
   b. Select the Upload a file to the Datastore icon in the icon menu.
   c. Navigate to the ISO files that you created in Preparing the portal subsystem for deployment.
      The API Connect ISO files are located in <project directory>/*<subsystem name>*plan-out
   d. Upload the ISO files to the datastore.
8. Leave the datastore by selecting the VMs and Templates icon in the Navigator.
9. Locate and select your virtual machine.
10. Select the Configure tab in the main window.
11. Select Edit....
    a. On the Virtual Hardware tab, select CD/DVD Drive 1.
    b. For the Client Device, select Datastore ISO File.
    c. Find and select your datastore in the Datastores category.
    d. Find and select your ISO file in the Contents category.
    e. Select OK to commit your selection and exit the Select File window.
    f. Ensure that the Connect At Power On checkbox is selected.
       Tip:
       - Expand the CD/DVD drive 1 entry to view the details and the complete Connect At Power On label.
    g. Select OK to commit your selection and close the window.
12. Start the virtual machine by selecting the play button on the icon bar.
    The installation might take several minutes to complete, depending on the availability of the system and the download speed.

What to do next

Verify your deployed portal VMs: Verifying installation of the portal subsystem.

Verifying installation of the portal subsystem

Verify that the portal subsystem installation succeeded.

Before you begin

Complete Deploying the portal subsystem OVA.

Procedure

1. Log in to the API Connect VM by using SSH, and check the status of the installation:
   If you are using a three replica deployment profile, then repeat this step for each VM in your portal subsystem deployment.

   a. Enter the following command to connect to your portal VM with SSH:

   ```
   ssh apicadm@<vm hostname>
   ```

   No password is required because you set your public key in step 10 on Preparing the portal subsystem for deployment. If necessary, include the path to your SSH identity files:

   ```
   ssh -i <path to identity file> apicadm@<vm hostname>
   ```

   For example:

   ```
   ssh -i ~/.ssh/id_rsa apicadm@<vm hostname>
   ```

b. Select Yes to continue connecting.
   Your hostnames are automatically added to your list of hosts.
c. Run the **apic status** command to verify that the installation completed and that the system is running correctly.
   The command output for a correctly running portal system is similar to the following:

```
$ sudo apic status
INFO[0000] Log level: info

```

2. Optional: Define multiple portal endpoints. See Defining multiple portal endpoints for a VMware environment.
3. Configure backups for your portal subsystem: Backing up and restoring the portal subsystem.

What to do next

If all API Connect subsystems are now installed, continue to Post-deployment steps.

Defining multiple portal endpoints for a VMware environment

Multiple public facing endpoints (**portal-www**) can be defined for the portal subsystem.

About this task

You can override the single endpoint definition for **portal-www**, and the associated **portal-www-ingress** TLS certificate, to support multiple **portal-www** endpoints.

For information about the portal endpoints, see Preparing the portal subsystem for deployment.

The task requires accessing your portal VM and creating Kubernetes secrets. Two methods are available for creating Kubernetes secrets:

- The recommended method uses a tool that exists on the portal VM called cert-manager. To use the cert-manager method, skip step 5.
- If you do not want to use the cert-manager method, you can create your Kubernetes secrets manually. Follow step 5 instead of steps 3 and 4.

Procedure

Create **portal-www** endpoint certificates with cert-manager.

1. Log in to your portal virtual appliance with an SSH client, as **apicadm** user

   ```
   ssh apicadm@<subsystem hostname>
   ```

2. Switch to the root user: **sudo -i**
3. Create a file called ingress-issuer.yaml and paste in the following content:

   ```
   apiVersion: cert-manager.io/v1
   kind: Certificate
   metadata:
     name: ingress-ca
   spec:
     secretName: ingress-ca
     commonName: "ingress-ca"
     usages:
     - digital signature
     - key encipherment
     - cert sign
     isCA: true
     duration: 87600h # 10 years
     renewBefore: 720h # 30 days
     privateKey:
       rotationPolicy: Always
     issuerRef:
       name: selfsigning-issuer
       kind: Issuer
   ---
   apiVersion: cert-manager.io/v1
   kind: Issuer
   metadata:
     name: ingress-issuer
   spec:
     ca:
       secretName: ingress-ca
   ```

   Run **kubectl apply -f ingress-issuer.yaml**.

   Keep a copy of the **ingress-issuer.yaml** file in your project directory, so that it is included in your portal subsystem backups.

4. Create cert-manager certificate objects for each **portal-www** endpoint.
   a. Create a file called portal-web-certs.yaml, and paste in a **Certificate** entry for each **portal-www** endpoint. In this example, two endpoints are created, so the example file contains two certificates:

      ```
      apiVersion: cert-manager.io/v1
      kind: Certificate
      metadata:
        labels:
          app.kubernetes.io/instance: portal
          app.kubernetes.io/managed-by: ibm-apiconnect
          app.kubernetes.io/name: web-endpoint
        name: portal-web-host1
        namespace: default
      spec:
        dnsNames:
        - <FQDN of portal web endpoint 1>
        duration: 17520h0m0s
        issuerRef:
          group: cert-manager.io
          kind: Issuer
          name: ingress-issuer
        renewBefore: 720h0m0s
        privateKey:
          rotationPolicy: Always
        secretName: portal-web-host1
        usages:
        - digital signature
        - key encipherment
      ---
      apiVersion: cert-manager.io/v1
      kind: Certificate
      metadata:
        labels:
          app.kubernetes.io/instance: portal
          app.kubernetes.io/managed-by: ibm-apiconnect
          app.kubernetes.io/name: web-endpoint
        name: portal-web-host2
        namespace: default
      spec:
        dnsNames:
        - <FQDN of portal web endpoint 2>
        duration: 17520h0m0s
        issuerRef:
          group: cert-manager.io
          kind: Issuer
          name: ingress-issuer
        renewBefore: 720h0m0s
      ```

```
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host2
  usages:
  - digital signature
  - key encipherment

---
apiVersion: cert-manager.io/v1
kind: Certificate
metadata:
  labels:
    app.kubernetes.io/instance: portal
    app.kubernetes.io/managed-by: ibm-apiconnect
    app.kubernetes.io/name: web-endpoint
  name: portal-web-host3
  namespace: default
spec:
  dnsNames:
  - <FQDN of portal web endpoint 3>
  duration: 17520h0m0s
  issuerRef:
    group: cert-manager.io
    kind: Issuer
    name: ingress-issuer
  renewBefore: 720h0m0s
  privateKey:
    rotationPolicy: Always
  secretName: portal-web-host3
  usages:
  - digital signature
  - key encipherment
```

b. Apply the file:

```
kubectl apply -f portal-web-certs.yaml
```

c. Keep a copy of the portal-web-certs.yaml file in your project directory, so that it is included in your portal subsystem backups.

Create **portal-www** without cert-manager.

5. Create Kubernetes secrets with OpenSSL. Follow this step instead of steps 3 and 4.
   To create the secrets and certificates for each **portal-www** endpoint, complete the following steps:
   a. If you are using self-signed certificates, create the TLS secrets for each **portal-www** endpoint by generating the certificates. The following example shows how to generate certificates for each **portal-www** endpoint by using OpenSSL:

```
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host1-tls.key -out ptl.host1-tls.crt -subj
"/CN=ptl.host1.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host2-tls.key -out ptl.host2-tls.crt -subj
"/CN=ptl.host2.example.com"
openssl req -x509 -nodes -days 365 -newkey rsa:2048 -keyout ptl.host3-tls.key -out ptl.host3-tls.crt -subj
"/CN=ptl.host3.example.com"
```

   b. Store the SSL certificates in a secret:
      i. Copy the certificates to the Portal virtual appliance, for example:

```
scp ptl.host1-tls.key ptl.host1-tls.crt ptl.host2-tls.key ptl.host2-tls.crt ptl.host3-tls.key ptl.host3-tls.crt
apicadm@portal-vm-address
```

      ii. Log in to your portal virtual appliance with an SSH client, as **apicadm** user
      iii. Switch to the root user: **sudo -i**
      iv. Create the Kubernetes secrets:

```
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host1 --key ptl.host1-tls.key --
cert ptl.host1-tls.crt
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host2 --key ptl.host2-tls.key --
cert ptl.host2-tls.crt
kubectl --kubeconfig /etc/kubernetes/admin.conf create secret tls portal-web-host3 --key ptl.host3-tls.key --
cert ptl.host3-tls.crt
```

      v. Keep a copy of your certificate files in your project directory, so that they are included in your portal subsystem backups.

Add **portal-www** endpoints and secrets to your **ptl-extra-values.yaml** file.

6. Exit from the portal VM, and in your **apicup** project directory, create a file called **ptl-extra-values.yaml** with the content:

```
spec:
    portalUIEndpoint:
        annotations: # Remove if cert-manager not used
          cert-manager.io/issuer: ingress-issuer # Remove if cert-manager not used
        hosts:
        - name: ptl.host1.example.com
          secretName: portal-web-host1
        - name: ptl.host2.example.com
          secretName: portal-web-host2
        - name: ptl.host3.example.com
          secretName: portal-web-host3
```

Note: If you followed step 5 and did not use cert-manager to create your secrets, then delete the **annotations** section, so your **ptl-extra-values.yaml** contains:

```
spec:
    portalUIEndpoint:
        hosts:
```

```
      - name: ptl.host1.example.com
        secretName: portal-web-host1
      - name: ptl.host2.example.com
        secretName: portal-web-host2
      - name: ptl.host3.example.com
        secretName: portal-web-host3
```

Run the commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>

apicup subsys install <ptl_subsys>
```

7. SSH back into your portal virtual appliance, and confirm that multiple hosts exist for your `ptl-portal-web` ingress:

```
sudo kubectl get ingress
NAME                 HOSTS                                                        ADDRESS   PORTS     AGE
ptl-portal-director  api.ptl.example.com                                                    80, 443   25m
ptl-portal-web       ptl.host1.example.com,ptl.host2.example.com,ptl.host3.example.com     80, 443   25m
```

Deploying DataPower Gateway virtual appliance

API Connect uses IBM® DataPower® Gateway to provide the gateway service.

The instructions in this section describe how to deploy IBM DataPower Gateway from files obtained from Passport Advantage®, and apply to the following API Connect scenarios:

- API Connect deployments for the VMware environment
- API Connect deployments for Kubernetes, with a DataPower Gateway in a *non-Kubernetes* environment.

For these scenarios, continue with Installing DataPower Gateway.

Note: Do not use these instructions if you are deploying API Connect deployments for Kubernetes, with DataPower Gateway in a *Kubernetes* environment. In this case, you can use DataPower Gateway files that are packaged with API Connect, on the API Connect section of Fix Central, and configured by using the API Connect `apicup` commands. Follow the instructions in Obtaining product files.

- **Installing DataPower Gateway**
  Install and configure IBM DataPower Gateway in a non-Kubernetes environment for use with API Connect.
- **Configuring DataPower Gateway for API Connect**
  You can configure the IBM DataPower Gateway to prepare for a registration with the API Connect Management server.
- **Best practices for enabling TLS in API Connect peer groups and managing certificate expiry**
- **Sample configuration for multiple peering objects on gateway services external to Kubernetes**
  Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

Installing DataPower Gateway

Install and configure IBM® DataPower® Gateway in a non-Kubernetes environment for use with API Connect.

Before you begin

Do not use these instructions for either of the following deployment scenarios:

- Both API Connect and DataPower Gateway in a Kubernetes environment.
  In this scenario, use the instructions in Obtaining product files.
- An existing DataPower Gateway in a non-Kubernetes environment, and you want to install a newer Fix Pack.
  In this scenario, complete an *upgrade* rather than a new installation. See Upgrading DataPower Gateway.

To review the installation and configuration scenarios, see Deploying DataPower Gateway virtual appliance.

Procedure

1. Ensure that the DataPower Gateway firmware version you plan to install is compatible with the API Connect management subsystem version.
   Note:
   Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software >. Integration Middleware, and view the list of compatible DataPower Gateway versions.
2. Obtain your DataPower files from IBM Passport Advantage®.
   Note that the DataPower files from Passport Advantage have entitled services for API Connect users.

   See also Download the firmware image from Passport Advantage.
3. Follow the DataPower Gateway installation information: https://www.ibm.com/docs/en/datapower-gateway.
   Note: Set the timezone to UTC on all DataPower installations for use with API Connect.
4. Continue with Configuring DataPower Gateway for API Connect.

Configuring DataPower Gateway for API Connect

You can configure the IBM® DataPower® Gateway to prepare for a registration with the API Connect Management server.

About this task

API Connect and DataPower supports two different types of gateway configurations. The DataPower Gateway (v5 compatible) provides the same support as the gateway support that was available with API Connect version 5.x. The DataPower API Gateway is an enhanced gateway that is performance-focused. See API Connect gateway types for more information about the differences between the gateway types.
Continue with the instructions for the type of Gateway Service you are configuring:

- **Configuring DataPower API Gateway**
  Configure the DataPower Gateway to prepare for registration with the API Connect Management server.
- **Configuring DataPower Gateway (v5 compatible)**
  You can configure the DataPower Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Configuring DataPower API Gateway

Configure the DataPower Gateway to prepare for registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower® API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see Deploying DataPower Gateway virtual appliance.
- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See Installing DataPower Gateway.
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the DataPower documentation for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the DataPower documentation for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower API Gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower API Gateway . If you are configuring DataPower Gateway (v5 compatible) see Configuring DataPower Gateway (v5 compatible).

1. Open the DataPower WebGUI interface.
   Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Enable the XML management interface in the default domain.
   To enable the XML management interface on the DataPower API Gateway, see Configuring the XML management interface to enable service endpoints.
   a. Search for XML management interface in the navigation search bar, and select it.
   b. Set the Administrative state to enabled.
   c. You can specify a different port number if you do not want to use the default of `5550`.
   d. Select Apply to make the changes
   e. Save changes to the default domain by selecting Save Configuration.
3. Optional: Enable the REST management interface in the default domain.
   The REST management interface is required if you want to enable to the Trace feature in the assembly Test tab in the API Manager.
   a. Search for REST management interface in the navigation search bar, and select it.
   b. Set the Administrative state to enabled.
   c. You can specify a different port number if you do not want to use the default of `5554`.
   d. Select Apply to make the changes
   e. Save changes to the default domain by selecting Save Configuration.
4. Create an application domain.
   This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
   a. Search for Application domain in the navigation search bar, and select it.
   b. Select Add to create the application domain.
   c. Enter a unique name for your domain.
   d. Ensure that enabled is selected for the Administrative state.
   e. Ensure that the default domain is listed in the Visible application domain list.

f. Select Apply.
g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
h. Select Save changes and switch domains.
All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
i. Save changes to the domain by selecting Save Configuration.

5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
You must configure the NTP service, the API Connect Gateway Service cannot run without it. See *Managing the NTP service* in the DataPower documentation.

6. Ensure that you have set a unique **`System Identifier`** for each v10 DataPower gateway. See *Initializing the DataPower Gateway* in the DataPower documentation.
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
a. Search for Crypto key in the navigation search bar, and select it.
b. Select Add to create a key object.
c. Create a unique name for the key object in the Name field.
d. Select Upload....
e. Browse for the key file (which must be a .pem or .p12 file) and select it.
f. If you want to rename it, enter a new name for the file.
g. Select Upload to move it to the server in the cert:// folder.
h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
a. Search for Crypto certificate in the navigation search bar, and select it.
b. Select Add to create a certificate object.
c. Create a unique name for the certificate object in the Name field.
d. Select Upload....
e. Browse for the key file (which must be a .pem or .p12 file) and select it.
f. If you want to rename it, enter a new name for the file.
g. Select Upload to move it to the server in the cert:// folder.
h. Select Apply to save the changes.
10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
b. Select Add.
c. Enter a name for your credential.
d. Ensure that the Administrative state has a value of enabled.
e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.
g. Select Apply to commit your changes.
11. Create your TLS Client profile.
a. Search for TLS Client profile in the navigation search bar, and select it.
b. Select Add to create a client profile.
c. Create a unique name for the profile in the Name field.
d. Select your Identification credential from the drop-down list.
e. Ensure that the value of Validate server certificate is set to off.
f. Ensure that the value of Use SNI is set to on.
g. Select Apply to save the changes.
12. Create your TLS Server profile.
The TLS Server profile secures your gateway director endpoint. When you register your gateway service in the Cloud Manager UI, the gateway returns the server certificate that you configure in this TLS Server profile.
a. Search for TLS Server Profile in the navigation search bar, and select it.
b. Select Add to create a server profile.
c. Create a unique name for the profile in the Name field.
d. Select your Identification credential from the drop-down list.
e. Select Apply to save the changes.
Important: Do not disable Request client authentication unless you enable JWT instead of mTLS. Client authentication is essential for secure mTLS communication between your management and gateway subsystems.
13. Define a configuration sequence.
The configuration sequence specifies how DataPower implements the APIs that are defined in API Connect.

a. Search for Configuration sequence in the navigation search bar, and select it.
b. Select Add.
c. Enter a name for your configuration sequence.
The name **`apic-config`** is not allowed because it is already used internally.

d. Ensure that the Administrative state has a value of enabled.
e. Ensure that the value in the Location profiles field is set to local:///
This is the default value, so you might not need to change it.
f. Select the Access profile.
For instructions on creating access profiles, see *Configuring the access profile for a configuration sequence* in the appropriate version of the DataPower documentation.

g. Change the value of the Configuration execution interval field to `3000`.
The other fields can retain their default settings.
h. Select Apply to commit your changes.
14. Configure your gateway peering object for the API Connect Gateway Service.
This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.
a. Search for Gateway peering in the navigation search bar, and select it.
b. Select Add.
c. Enter a unique name for your gateway peering object.

d. Ensure that the Administrative state has a value of enabled.
e. Select a local address for the communications among the members of the peer group.
f. Select a local port for the communication.
You can use the default value of 16380.
g. Select a monitor port for the communication.
You can use the default value of 26380.
h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
i. Clear the Enable TLS check box. TLS is not needed for a single peer.
j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
k. Select Apply to commit your changes.

If you want to update the peering the certificate later, then see Updating the gateway peering certificate.

15. Configure your gateway peering object for rate limit information.
a. Search for Gateway peering in the navigation search bar, and select it.
b. Select Add.
c. Enter a unique name for your gateway peering object.
d. Ensure that the Administrative state has a value of enabled.
e. Select a local address for the communications among the members of the peer group.
f. Select a local port for the communication.
Use a unique port, different than the ports used for communication by other gateway peering objects.
g. Select a monitor port for the communication.
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
i. Clear the Enable TLS check box. TLS is not needed for a single peer.
j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
k. Select Apply to commit your changes.
16. Optional: If you are using the ratelimit module described in the DataPower documentation, configure your gateway peering object for GatewayScript rate limiting information.
a. Search for Gateway peering in the navigation search bar, and select it.
b. Select Add.
c. Enter a unique name for your gateway peering object.
d. Ensure that the Administrative state has a value of enabled.
e. Select a local address for the communications among the members of the peer group.
f. Select a local port for the communication.
Use a unique port, different than the ports used for communication by other gateway peering objects.
g. Select a monitor port for the communication.
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
i. Clear the Enable TLS check box. TLS is not needed for a single peer.
j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
k. Select Apply to commit your changes.
17. Configure your gateway peering object for subscription information.
a. Search for Gateway peering in the navigation search bar, and select it.
b. Select Add.
c. Enter a unique name for your gateway peering object.
d. Ensure that the Administrative state has a value of enabled.
e. Select a local address for the communications among the members of the peer group.
f. Select a local port for the communication.
Use a unique port, different than the ports used for communication by other gateway peering objects.
g. Select a monitor port for the communication.
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
i. Clear the Enable TLS check box. TLS is not needed for a single peer.
j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
k. Select Apply to commit your changes.
18. Configure the gateway peering object for the API probe.
In order for API Connect to receive trace data in the Test tab's debugger, the DataPower API Gateway must be configured to support the API probe.

a. Search for Gateway peering in the navigation search bar, and select it.
b. Select Add.
c. Enter a unique name for your gateway peering object.
d. Ensure that the Administrative state has a value of enabled.
e. Select a local address for the communications among the members of the peer group.
f. Select a local port for the communication.
Use a unique port, different than the ports used for communication by other gateway peering objects.
g. Select a monitor port for the communication.
Use a unique port, different than the ports used for monitoring by other gateway peering objects.
h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
i. Clear the Enable TLS check box. TLS is not needed for a single peer.
j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
k. Select Apply to commit your changes.
19. Configure the gateway peering manager.
a. Search for Gateway Peering Manager in the navigation search bar, and select it.
b. Set the Administrative state to enabled.
c. In the pull-down menu next to API Connect Gateway Service, select the gateway peering object configured in Step 14 for the API Connect Gateway Service.
d. In the pull-down menu next to Rate Limit, select the gateway peering object configured in Step 15 for rate limit information.
e. In the pull-down menu next to Subscription, select the gateway peering object configured in Step 17 for subscription.
f. In the pull-down menu next to API Probe, select the gateway peering object that you configured in Step 18 for the API probe.
g. If you are using the ratelimit module described in the DataPower documentation, then for GatewayScript rate limiting, select the gateway peering object that you configured in Step 16 for rate limit information.

h. Select Apply to commit your changes.

20. Configure the API probe settings object.
    a. Search for API probe settings in the navigation search bar, and select it.
    b. Set the Administrative state to enabled.
    c. Set the maximum number of records to `1000`.
    d. Set the expiration to `60` minutes.
    e. In the pull-down menu next to Gateway Peering, select the gateway peering object that you configured in Step 18 for the API probe.
    f. Select Apply to commit your changes.
21. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
    a. Search for API Connect Gateway service in the navigation search bar, and select it.
    b. Ensure that the Administrative state is set to enabled.
    c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
    d. Specify a value for Local port. You can use the default value of 3000, or specify a different port value.
    Note: The Local port specifies the port through which API Connect connects to manage the API Connect Gateway Service. Use this port when you configure a Gateway Service on API Connect.
    e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
    f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
    g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
    h. Use the default port value of 9443 for the API gateway port.
    If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
    i. For DataPower API Gateway, set the Gateway Peering to **`(default gateway-peering)`**.
    When no gateway peering object is configured for the DataPower API Gateway, the peering configuration defined in the Gateway Peering Manager configuration is used.
    j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.
    When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway. Clear it to enable a DataPower API Gateway.
22. Optional: Enable JWT security instead of mTLS for communication from management to gateway. JWT security provides application layer security and can be used instead of mTLS when load-balancers are located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.
    To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the DataPower documentation. The JWKS URL required to enable JWT security can be found in the management subsystem settings:

    ```
    apicup subsys get <management subsystem name>

    ...
    jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
    validate JWT -- this is unsettable and is generated based on the platform-api endpoint
    ...
    ```

23. Register the gateway service in the API Connect Cloud Manager console:
    a. Open the API Connect Cloud Manager console.
    b. Navigate to Configure Topology.
    c. Select Register Service.
    d. Select DataPower API Gateway for the DataPower API Gateway.
    e. Add a title, name, and summary for the gateway connection.
    f. Optional: Configure the OAuth Shared Secret.
    This setting allows OAuth tokens to be shared across multiple gateway services.
    g. Enter one of the following values in the API Invocation Endpoint field:
        - Fully qualified domain name of the load balancer for the API transactions
        - Fully qualified domain name of one of the gateways

    Note: You can also add load balancer or gateway IP address in the API Invocation Endpoint field, but it is recommended to use the fully qualified domain names.
    For example:**`https://API-endpoint.DomainName:9443/`**
    h. Enter the one of the following values in the Management Endpoint field:
        - Fully qualified domain name of the load balancer for the management server traffic set to port 3000
        - Fully qualified domain name of one of the gateways

    Note: You can also add load balancer or gateway IP address in the Management Endpoint field, but it is recommended to use the fully qualified domain name.
    For example:**`https://Gateway-Mgmt.DomainName:3000/`**
24. Select the default TLS Client Profile
25. Optional: Configure Server Name Indication (SNI) profiles.
    SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.
26. Enable logging for the gateway.
    a. Use the CLI to configure the following log target in the API Connect application domain:

    ```
    switch domain <apiconnect_domain>
    configure terminal
    logging target gwd-log
    type file
    format text
    timestamp zulu
    size 50000
    local-file logtemp:///gwd-log.log
    event apic-gw-service debug
    exit
    apic-gw-service;admin-state disabled;exit
    apic-gw-service;admin-state enabled;exit
    write mem
    exit
    ```

    b. Repeat this set for every gateway server in the cluster.

Configuring DataPower Gateway (v5 compatible)

You can configure the DataPower Gateway (v5 compatible) to prepare for a registration with the API Connect Management server.

Before you begin

- These instructions are for DataPower® API Gateway deployments in a non-Kubernetes environment. Do not use these instructions if you installed API Connect on Kubernetes, with your DataPower API Gateway Service also in the Kubernetes environment. To review deployment scenarios, see Deploying DataPower Gateway virtual appliance.
- Ensure you have installed a version of DataPower API Gateway that is compatible with the version of the API Connect Management server. See Installing DataPower Gateway.
- A shared certificate and private key is used for securing the communication between the API Connect Management server and the gateway. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create them with the DataPower tools.
- Ensure that the time zone for the DataPower API Gateway is set to UTC.

About this task

- These instructions provide the basic steps for configuring a gateway service with a single gateway server. The lowest-level configuration objects are created first, then used in other configuration objects.
- Adding gateways to configure a peering environment is similar to creating the first gateway, and is recommended for resiliency in a production environment. A minimum of three gateway servers in a gateway service is recommended for high availability. See *Gateway peering* in the DataPower documentation for more information about configuring additional gateways for peering. See *Providing the gateway service to API Connect* in the DataPower documentation for more details about the DataPower settings and procedures.

Procedure

To configure a DataPower gateway to communicate with API Connect, complete the following steps:

Note: Use these instructions only for DataPower Gateway (v5 compatible). If you are configuring DataPower API Gateway, see Configuring DataPower API Gateway.

1. Open the DataPower WebGUI interface.
   Most of the configuration procedure is done in the DataPower WebGUI interface, not in the Blueprint Console.
2. Enable the XML management interface in the default domain.
   To enable the XML management interface on the DataPower API Gateway, see Configuring the XML management interface to enable service endpoints.
   a. Search for **XML management interface** in the navigation search bar, and select it.
   b. Set the Administrative state to enabled.
   c. You can specify a different port number if you do not want to use the default of `5550`.
   d. Select Apply to make the changes
   e. Save changes to the default domain by selecting Save Configuration.
3. Create an application domain.
   This domain receives your traffic. The name of the DataPower domain where you configure the API Connect Gateway Service must be the same on each DataPower Gateway.
   a. Search for Application domain in the navigation search bar, and select it.
   b. Select Add to create the application domain.
   c. Enter a unique name for your domain.
   d. Ensure that enabled is selected for the Administrative state.
   e. Ensure that the default domain is listed in the Visible application domain list.
   f. Select Apply.
   g. Change to your new application domain by selecting Domain in the menu bar, and selecting the domain that you created.
   h. Select Save changes and switch domains.
   All of the remaining steps on the DataPower gateway must be done in the application domain that you created.
   i. Save changes to the domain by selecting Save Configuration.
4. For the DataPower Gateway (v5 compatible) only: Enable statistics in the domain you created for API Connect.
   a. Search for and select Statistics settings in the navigation search.
   b. Select enabled for the Administrative state.
   c. Select Apply.
5. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways.
   See Managing the NTP service.
6. Ensure that you have set a unique `System Identifier` for each v10 DataPower gateway. See Initializing the DataPower Gateway.
7. Create a self-signed certificate and private key to be used to protect the traffic between the management server and the API gateway service process. You can generate a certificate and private key using DataPower or by using other tools, such as **OpenSSL**. See *Generating keys and certificates* in the appropriate version of the DataPower documentation for instructions on how to create a crypto key with the DataPower tools.
8. Upload your private crypto key file to the domain.
   a. Search for Crypto key in the navigation search bar, and select it.
   b. Select Add to create a key object.
   c. Create a unique name for the key object in the Name field.
   d. Select Upload....
   e. Browse for the key file (which must be a .pem or .p12 file) and select it.
   f. If you want to rename it, enter a new name for the file.
   g. Select Upload to move it to the server in the cert:// folder.
   h. Select Apply to save the changes.
9. Upload your crypto certificate file to the domain.
   Note: If your certificate is signed by an Intermediate CA, you must include the entire chain in a single key file (either .pem or .p12) for uploading.
   a. Search for Crypto certificate in the navigation search bar, and select it.
   b. Select Add to create a certificate object.
   c. Create a unique name for the certificate object in the Name field.
   d. Select Upload....
   e. Browse for the key file (which must be a .pem or .p12 file) and select it.
   f. If you want to rename it, enter a new name for the file.

g. Select Upload to move it to the server in the cert:// folder.
h. Select Apply to save the changes.

10. Associate the Crypto key with the Crypto certificate by setting the Identification credential.
    a. Search for Crypto Identification Credentials in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a name for your credential.
    d. Ensure that the Administrative state has a value of enabled.
    e. In the Crypto Key field, select the name of the key object that you created from the drop-down menu.
    f. In the Certificate object field, select the name of the certificate object that you created from the drop-down menu.
    g. Select Apply to commit your changes.
11. Create your TLS Client profile.
    a. Search for TLS Client profile in the navigation search bar, and select it.
    b. Select Add to create a client profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Ensure that the value of Validate server certificate is set to off.
    f. Ensure that the value of Use SNI is set to on.
    g. Select Apply to save the changes.
12. Create your TLS Server profile.
    The TLS Server profile secures your gateway director endpoint. When you register your gateway service in the Cloud Manager UI, the gateway returns the server certificate that you configure in this TLS Server profile.
    a. Search for TLS Server Profile in the navigation search bar, and select it.
    b. Select Add to create a server profile.
    c. Create a unique name for the profile in the Name field.
    d. Select your Identification credential from the drop-down list.
    e. Select Apply to save the changes.

    Important: Do not disable Request client authentication unless you enable JWT instead of mTLS. Client authentication is essential for secure mTLS communication between your management and gateway subsystems.
13. Configure your gateway peering object for the API Connect Gateway Service.
    This step is required when you set up a peer group of gateways, even if there is only a single gateway server in the gateway service.
    a. Search for Gateway peering in the navigation search bar, and select it.
    b. Select Add.
    c. Enter a unique name for your gateway peering object.
    d. Ensure that the Administrative state has a value of enabled.
    e. Select a local address for the communications among the members of the peer group.
    f. Select a local port for the communication.
       You can use the default value of 16380.
    g. Select a monitor port for the communication.
       You can use the default value of 26380.
    h. Because this procedure uses only one gateway, ensure that Peer group mode is not selected.
    i. Clear the Enable TLS check box. TLS is not needed for a single peer.
    j. Set the Persistence location value to **`Memory`** for either physical DataPower appliance or virtual DataPower appliance.
    k. Select Apply to commit your changes.

    If you want to update the peering the certificate later, then see Updating the gateway peering certificate.

14. Set the API Connect Gateway service to define the communication interface with the API Connect Management server and for API transactions.
    a. Search for API Connect Gateway service in the navigation search bar, and select it.
    b. Ensure that the Administrative state is set to enabled.
    c. In the Local address field, enter the IP address of the DataPower gateway to which you want the traffic from the API Connect Management server to be sent.
    d. Use the default port value of 3000 for the Local port.
    e. In the TLS client field drop-down list, select the name of the TLS client profile that you created.
    f. In the TLS server field drop-down list, select the name of the TLS server profile that you created.
    g. In the API gateway address field, enter the IP address for the DataPower gateway to which you want the API traffic sent.
    h. Use the default port value of 9443 for the API gateway port.
       If the port is not being used by another service, you can also change it to port 443 if you want API transactions to be sent to the default port for HTTPS.
    i. For DataPower Gateway (v5 compatible), select the gateway peering object that you created in Step 13.
    j. Select whether you want the DataPower Gateway (v5 compatible) or the DataPower API Gateway.
       When the option is selected, it enables the registration of a DataPower Gateway (v5 compatible) gateway.
15. Optional: Enable JWT security instead of mTLS for communication from management to gateway. JWT security provides application layer security and can be used instead of mTLS when load-balancers are located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.
    To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the DataPower documentation. The JWKS URL required to enable JWT security can be found in the management subsystem settings:

    ```
    apicup subsys get <management subsystem name>

    ...
    jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
    validate JWT -- this is unsettable and is generated based on the platform-api endpoint
    ...
    ```

16. Register the gateway service in the API Connect Cloud Manager console:
    a. Open the API Connect Cloud Manager console.
    b. Navigate to Configure Topology.
    c. Select Register Service.
    d. Select DataPower Gateway (v5 compatible) for the gateway that was available in version 5.
    e. Add a title, name, and summary for the gateway connection.
    f. Optional: Configure the OAuth Shared Secret.
       This setting allows OAuth tokens to be shared across multiple gateway services.
    g. Enter one of the following values in the API Invocation Endpoint field:
       - Fully qualified domain name of the load balancer for the API transactions

- Fully qualified domain name of one of the gateways

Note: You can also add load balancer or gateway IP address in the API Invocation Endpoint field, but it is recommended to use the fully qualified domain names.

For example:`https://API-endpoint.DomainName:9443/`

h. Enter the one of the following values in the Management Endpoint field:
- Fully qualified domain name of the load balancer for the management server traffic set to port 3000
- Fully qualified domain name of one of the gateways

Note: You can also add load balancer or gateway IP address in the Management Endpoint field, but it is recommended to use the fully qualified domain names.

For example:`https://Gateway-Mgmt.DomainName:3000/`

17. Select the default TLS Client Profile
18. Optional: Configure Server Name Indication (SNI) profiles.
SNI profiles allow different TLS certificates to be used for API transaction requests from different host names.
19. Enable logging for the gateway.
a. Use the CLI to configure the following log target in the API Connect application domain:

```
switch domain <apiconnect_domain>
configure terminal
logging target gwd-log
type file
format text
timestamp zulu
size 50000
local-file logtemp:///gwd-log.log
event apic-gw-service debug
exit
apic-gw-service;admin-state disabled;exit
apic-gw-service;admin-state enabled;exit
write mem
exit
```

b. Repeat this set for every gateway server in the cluster.

Best practices for enabling TLS in API Connect peer groups and managing certificate expiry

Learn best practices for enabling TLS in API Connect peer groups, ensuring secure communication between gateways, and managing certificate expiration to prevent disruptions.

- When enabling peer groups with Transport Layer Security (TLS) enabled in IBM® API Connect, it's crucial to configure peering objects on all gateways with certificates from a common issuer. This means that the certificates should either be identical across all gateways or signed by the same Certificate Authority (CA). The CA's public certificate should be included in the validation credential `(valcred)` object used by the peering objects.
- If the individual certificates (`idcred`) are nearing their expiration date, replace them with new certificates signed by the same CA. This ensures a seamless transition without disruptions.
- However, if the CA's certificate itself is nearing its expiration date, additional steps are required. You'll need to add the new CA's public certificate to the `valcred` object on all gateways. Subsequently, update the peering objects' `idcred` object to utilize certificates signed by the new CA. Finally, remove the old CA's public certificate from the `valcred` objects. This process ensures continuous, secure communication between gateways while maintaining the integrity of the TLS configuration

Summary

- **Certificates**: Use a common CA for all gateways to ensure mutual trust.
- **Certificate Rotation**: Replace expiring certificates with new ones from the same CA without disruption.
- **CA Rotation**: If the CA itself is being replaced, follow a structured process to update the `valcred` and `idcred` objects across all gateways.
- **TLS Implications**: If TLS is enabled for peering, ensure that the certificates are consistently managed and updated as described.

Configuring a gateway with TLS enabled peering

First configure `idcred` and `valcred`.

```
crypto
      key         peering_key     cert:///peering-key.pem
      certificate peering_cert    cert:///peering-cert.pem
      certificate peering_ca      cert:///peering-ca.pem
      idcred      peering_idcred  peering_key peering_cert ca peering_ca
      valcred     peering_valcred ; certificate peering_ca ; exit
    exit
```

Then, add the following configuration to each `gateway-peering` object:

```
enable-ssl on
      idcred peering_idcred
      valcred peering_valcre
```

- The priority should be set differently on each gateway. Set the lowest priority for the gateway that will run as primary.
- `persistence` should be set to `memory` for all configured peering objects.

The following example configures gateway (1.1.1.1) with TLS enabled peering.

```
    gateway-peering subs
      admin enabled
      local-address 1.1.1.1
      local-port 15222
      monitor-port 26222
      priority 100
```

```
    enable-ssl on
    idcred peering_idcred
    valcred peering_valcred
    enable-peer-group on
    peer 2.2.2.2
    peer 3.3.3.3
    persistence memory
  exit

  gateway-peering rate-limit
    admin enabled
    local-address 1.1.1.1
    local-port 15223
    monitor-port 26223
    priority 100
    enable-ssl on
    idcred peering_idcred
    valcred peering_valcred
    enable-peer-group on
    peer 2.2.2.2
    peer 3.3.3.3
    persistence memory
  exit
```

Sample configuration for multiple peering objects on gateway services external to Kubernetes

Sample for reconfiguring the API Connect domain configuration for your gateway services to include multiple peering objects.

- This reference shows how to configure API Connect domain configuration with gateway-peering configuration. To review domain configuration settings, see Configuring DataPower Gateway for API Connect.
- This sample applies only to gateway services that are deployed external to Kubernetes, on either a physical or virtual appliance. This sample does not apply to gateway services that are deployed on Kubernetes.

The following examples show sample configuration for 3 different gateways, listed here with sample IP addresses of 1.1.1.1, 2.2.2.2, and 3.3.3.3. Note the following:

- The priority should be set differently on each of the three gateways. Set the lowest priority for the gateway that will run as primary.
- `persistence` should be set to `memory` for all configured peering objects.
- Optionally, add SSL configuration.

Configuration on gateway 1 (1.1.1.1)

```
top; configure terminal;
  domain apiconnect; visible default; exit;

  sw apiconnect;

  loglevel debug;
  logging target gwd-log
    type file
    format text
    timestamp syslog
    size 50000
    local-file logtemp:///gwd-log
    event apic-gw-service debug
  exit

  config-sequence "apiconnect"
    location "local:///"
    watch "on"
    delete-unused "on"
    match "(.*)\.cfg$"
    summary "Toolkit Reboot configuration"
    run-sequence-interval 3000
    optimize-for-apic on
  exit

    exit

    write mem
```

Post-deployment steps

When all subsystems are deployed, login to the Cloud Manager UI and begin configuration.

Procedure

1. Verify that you can access the API Connect Cloud Manager UI. Enter the following URL in your browser.
   The syntax is **`https://<cloud admin ui endpoting>/admin`**. For example:

   `https://<cloud admin ui endpoint>/admin`

   where *<cloud admin ui endpoint>* is the endpoint that you specified in step 9 in Preparing the management subsystem for deployment.

   The first time that you access the Cloud Manager UI, enter `admin` for the username and `7iron-hide` for the password. You are then prompted to change the Cloud Manager UI admin password and email address. See Accessing the Cloud Manager user interface.

2. Define your API Connect configuration in the Cloud Manager UI. See Cloud Manager configuration checklist.
3. Take backups of your project directory and configure scheduled backups of all your subsystem databases. See Backing up and restoring on VMware.
4. Optional: Take a virtual machine (VM) snapshot of all your VMs; see Using VM snapshots for infrastructure backup and disaster recovery for details. This action does require a brief outage while the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can offer a faster recovery when compared to redeploying OVAs and restoring subsystems from database backups.
   Important: VM snapshots are not an alternative to the standard API Connect backups described in step 3. Always take project directory and subsystem database backups.

Installing a two data center deployment

How to install a two data center disaster recovery (2DCDR) deployment on VMware.

Before you begin

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see Two data center warm-standby deployment strategy on VMware.

Review the information in VMware deployment overview and requirements.

Familiarize yourself with the instructions in Preparing to install API Connect in VMware. Complete these instructions with the additional steps in this topic that are specific to installing a 2DCDR deployment.

Restriction: It is not possible to use the Automated API behavior testing application (Installing the Automated API behavior testing application) in a 2DCDR configuration.

About this task

Installing API Connect as a 2DCDR deployment is similar to a single installation. The deployment in each data center is effectively an instance of the same API Connect deployment. The following endpoints must be the same on both data centers:

Management subsystem endpoints

- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`
- `consumer-catalog-ui`

Portal subsystem endpoints

- `portal-admin`
- `portal-www`

To install a 2DCDR deployment, you follow the normal stand-alone API Connect installation steps, but before you generate the ISO files you must set some additional 2DCDR properties.

The 2DCDR properties are described in the following table.

Table 1. 2DCDR properties

Setting	Description
`multi-site-ha-enabled`	Indicates whether 2DCDR deployment is enabled. Set to `true` to enable 2DCDR. Set to `false` to disable 2DCDR. The default value is `false`.
`multi-site-ha-mode`	The 2DCDR mode of the data center. Possible values are: • `active` - indicates the primary data center. • `passive` - indicates the warm-standby data center.
`management-replication`	Required only for the management subsystem. The external ingress name for the management subsystem in the current data center in the 2DCDR deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`portal-replication`	Required only for the portal subsystem. The external ingress name for the portal subsystem in the current data center in the 2DCDR deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`replication-peer-fqdn`	The ingress hostname for the other data center in the 2DCDR deployment. This information is required so that the two data centers can communicate with each other.
`siteName`	Unique descriptive name for the API Connect data center. Must be different in each data center. This name is used in the hostnames, and so can contain only `a-z` and `0-9` characters. You can set a `siteName` only when the subsystems are first deployed, and you cannot change the name after deployment. If you don't set `siteName` at first deployment, the `siteName` is autogenerated.

Important: Use a single project directory for all subsystems so that the API Connect deployments in both data centers have the same certificate chains. If network access to both data centers from the same project directory is not possible, you can copy the project directory across to the other data center. If you are copying the project directory to your other data center, ensure that you keep backups of both project directories.

Procedure

- **Installing on the active data center**
  The following example shows how to configure the 2DCDR settings for deploying on the active data center (DC). In this example, the active data center is called `dallas` (DC1), and the warm-standby data center is called `raleigh` (DC2).

  1. Complete the steps in Preparing the management subsystem for deployment up to step 18 to configure the standard (non-2DCDR) settings for the management subsystem in Dallas (DC1).
  2. Configure the 2DCDR values to set Dallas to be active for the management subsystem in DC1.
     Run the following commands:

     ```
     apicup subsys set mgmt_dallas multi-site-ha-enabled=true

     apicup subsys set mgmt_dallas multi-site-ha-mode=active

     apicup certs set mgmt_dallas management-replication-ingress --clear

     apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com

     apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com

     apicup subsys set mgmt_dallas site-name=dallas
     ```

     where
     - *`mgmt_dallas`* is the name of the management subsystem that you are configuring.
     - *`mgrreplicationdallas.cluster1.example.com`* is the ingress hostname for the current data center in the two data center deployment.
     - *`mgrreplicationraleigh.cluster2.example.com`* is the ingress hostname for the other data center in the two data center deployment.
     - *`dallas`* is the name of the site in the current data center.
  3. Complete the remainder of the steps in Preparing the management subsystem for deployment from step 18 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
  4. Complete the steps in Preparing the portal subsystem for deployment up to step 21 to configure the standard (non-2DCDR) settings for the portal subsystem in Dallas (DC1).

5. Configure the 2DCDR values to set Dallas to be active for the portal subsystem in DC1.
   Run the following commands:

   ```
   apicup subsys set port_dallas multi-site-ha-enabled=true

   apicup subsys set port_dallas multi-site-ha-mode=active

   apicup certs set port_dallas portal-replication-ingress --clear

   apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com

   apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com

   apicup subsys set port_dallas site-name=dallas
   ```

   where
   - `port_dallas` is the name of the portal subsystem that you are configuring.
   - `ptlreplicationdallas.cluster1.example.com` is the ingress hostname for the current data center in the two data center deployment.
   - `ptlreplicationraleigh.cluster2.example.com` is the ingress hostname for the other data center in the two data center deployment.
   - `dallas` is the name of the site in the current data center.
6. Complete the remainder of the steps in Preparing the portal subsystem for deployment from step 21 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
7. Check the status of the installation by running:

   ```
   apicup subsys status subsystem_name
   ```

8. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

   Management subsystem endpoints
   - `platform-api`
   - `consumer-api`
   - `cloud-admin-ui`
   - `api-manager-ui`
   - `consumer-catalog-ui`

   Portal subsystem endpoints
   - `portal-admin`
   - `portal-www`

- **Installing on the warm-standby data center**
  The following example shows how to set the 2DCDR values for the remote data center called `raleigh` (DC2), which is being installed as the warm-standby location.

  Important: Remember to use the same project directory as for the active data center. If you cannot use the same project directory because its location does not have network access to both data centers, you can copy the project directory over. Ensure that backups are kept of both project directories in each data center.
  1. Complete the steps in Preparing the management subsystem for deployment up to step 18 to configure the standard (non-2DCDR) settings for the management subsystem in Raleigh (DC2).
  2. Configure the 2DCDR values to set the management subsystem to be the warm-standby in the Raleigh (DC2) data center.
     Run the following commands:

     ```
     apicup subsys set mgmt_raleigh multi-site-ha-enabled=true

     apicup subsys set mgmt_raleigh multi-site-ha-mode=passive

     apicup certs set mgmt_raleigh management-replication-ingress --clear

     apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com

     apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com

     apicup subsys set mgmt_raleigh site-name=raleigh
     ```

     where
     - `mgmt_raleigh` is the name of the management subsystem that you are configuring.
     - `mgrreplicationraleigh.cluster2.example.com` is the ingress hostname for the current data center in the two data center deployment.
     - `mgrreplicationdallas.cluster1.example.com` is the ingress hostname for the other data center in the two data center deployment.
     - `raleigh` is the name of the site in the current data center.
  3. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).
     Run the following commands:

     ```
     apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret

     apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret
     ```

  4. Check that the management encryption key is set the same on both DC1 and DC2.
     Run the following commands, and verify that the outputs match:

     ```
     apicup certs get mgmt_dallas encryption-secret -t key

     apicup certs get mgmt_raleigh encryption-secret -t key
     ```

  5. Complete the remainder of the steps in Preparing the management subsystem for deployment from step 18 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
  6. Complete the steps in Preparing the portal subsystem for deployment up to step 21 to configure the standard (non-2DCDR) settings for the portal subsystem in Raleigh (DC2).
  7. Configure the 2DCDR values to set Raleigh to be warm-standby for the portal subsystem on DC2.
     Run the following commands:

     ```
     apicup subsys set port_raleigh multi-site-ha-enabled=true

     apicup subsys set port_raleigh multi-site-ha-mode=passive
     ```

```
apicup certs set port_raleigh portal-replication-ingress --clear

apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com

apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com

apicup subsys set port_raleigh site-name=raleigh
```

where

- *port_raleigh* is the name of the portal subsystem that you are configuring.
- *ptlreplicationraleigh.cluster2.example.com* is the ingress hostname for the current data center in the two data center deployment.
- *ptlreplicationdallas.cluster1.example.com* is the ingress hostname for the other data center in the two data center deployment.
- *raleigh* is the name of the site in the current data center.

8. Copy the encryption key for the portal subsystem on DC1 over to the portal subsystem on DC2.
   Run the following command to get the encryption key for the portal subsystem on DC1, and put it into a file that is called port-encryption-secret:

   ```
   apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
   ```

   Run the following command to use the port-encryption-secret file to set the same encryption key on DC2:

   ```
   apicup certs set port_raleigh encryption-secret port-encryption-secret
   ```

   Where *port_dallas* is the name of the portal subsystem on DC1, and *port_raleigh* is the name of the portal subsystem on DC2.
   To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

   ```
   apicup certs get port_dallas encryption-secret -t key

   apicup certs get port_raleigh encryption-secret -t key
   ```

9. Complete the remainder of the steps in Preparing the portal subsystem for deployment from step 21 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
10. Check the status of the installation by running:

    ```
    apicup subsys status subsystem_name
    ```

- **Converting a single data center deployment to two data centers**
  Important:
  - Use the existing deployment as the active site. The new site must be set to warm-standby. If you set your existing deployment to warm-standby then all your management and portal data is erased.
  - The ingress endpoint values from the existing deployment become the global ingress endpoints for the two center deployment. The following endpoints must be set the same on your new deployment, as they are on your existing deployment:

    Management subsystem endpoints
    - `platform-api`
    - `consumer-api`
    - `cloud-admin-ui`
    - `api-manager-ui`
    - `consumer-catalog-ui`

    Portal subsystem endpoints
    - `portal-admin`
    - `portal-www`

  - Configure your network to be able to route the endpoints to either data center, depending on which is the active.
  - You cannot configure a `site-name` for the existing management or portal cluster because the `site-name` property can be configured only at first deployment.

  The following example shows how to update the 2DCDR values to make the existing data center `Dallas` the active, and for installing and setting the new remote data center `Raleigh` as warm-standby.

  1. Configure the 2DCDR values to set Dallas to be active for the management subsystem on DC1.
     Run the following commands:

     ```
     apicup subsys set mgmt_dallas multi-site-ha-enabled=true

     apicup subsys set mgmt_dallas multi-site-ha-mode=active

     apicup certs set mgmt_dallas management-replication-ingress --clear

     apicup subsys set mgmt_dallas management-replication=mgrreplicationdallas.cluster1.example.com

     apicup subsys set mgmt_dallas replication-peer-fqdn=mgrreplicationraleigh.cluster2.example.com
     ```

     where
     - *mgmt_dallas* is the name of the management subsystem that you are configuring.
     - *mgrreplicationdallas.cluster1.example.com* is the ingress hostname for the current data center in the two data center deployment.
     - *mgrreplicationraleigh.cluster2.example.com* is the ingress hostname for the other data center in the two data center deployment.

     Note: As the management subsystem already exists, you cannot set the `site-name` property.
  2. Configure the 2DCDR values to set Dallas to be active for the portal subsystem on DC1.
     Run the following commands:

     ```
     apicup subsys set port_dallas multi-site-ha-enabled=true

     apicup subsys set port_dallas multi-site-ha-mode=active

     apicup certs set port_dallas portal-replication-ingress --clear

     apicup subsys set port_dallas portal-replication=ptlreplicationdallas.cluster1.example.com

     apicup subsys set port_dallas replication-peer-fqdn=ptlreplicationraleigh.cluster2.example.com
     ```

     where

- ***port_dallas*** is the name of the portal subsystem that you are configuring.
- ***ptlreplicationdallas.cluster1.example.com*** is the ingress hostname for the current data center in the two data center deployment.
- ***ptlreplicationraleigh.cluster2.example.com*** is the ingress hostname for the other data center in the two data center deployment.

Note: As the portal subsystem already exists, you cannot set the **site-name** property.

3. Run **apicup** to update the settings in each subsystem, for example:

```
apicup subsys install subsystem_name
```

where ***subsystem_name*** is the name of the management or portal subsystem that you want to update, for example ***mgmt_dallas***.

4. Check the status of the installation by running:

```
apicup subsys status subsystem_name
```

5. Add the new DC, Raleigh (DC2) by completing the steps in Preparing the management subsystem for deployment up to step 18 to create a management subsystem in Raleigh (DC2).
Note:
   - Remember to use the same project directory as for the active data center.
   - Remember to set the same endpoints as for DC1:

     Management subsystem endpoints
     - **platform-api**
     - **consumer-api**
     - **cloud-admin-ui**
     - **api-manager-ui**
     - **consumer-catalog-ui**

     Portal subsystem endpoints
     - **portal-admin**
     - **portal-www**

6. Configure the 2DCDR values to set Raleigh to be warm-standby for the management subsystem on DC2.
Run the following commands:

```
apicup subsys set mgmt_raleigh multi-site-ha-enabled=true

apicup subsys set mgmt_raleigh multi-site-ha-mode=passive

apicup certs set mgmt_raleigh management-replication-ingress --clear

apicup subsys set mgmt_raleigh management-replication=mgrreplicationraleigh.cluster2.example.com

apicup subsys set mgmt_raleigh replication-peer-fqdn=mgrreplicationdallas.cluster1.example.com

apicup subsys set mgmt_raleigh site-name=raleigh
```

where
   - ***mgmt_raleigh*** is the name of the management subsystem that you are configuring.
   - ***mgrreplicationraleigh.cluster2.example.com*** is the ingress hostname for the current data center in the two data center deployment.
   - ***mgrreplicationdallas.cluster1.example.com*** is the ingress hostname for the other data center in the two data center deployment.
   - ***raleigh*** is the name of the site in the current data center.

Note: As this is a new deployment of the management subsystem, you can set the **site-name** property.

7. Set the encryption key manually for Raleigh (DC2) by copying it from Dallas (DC1).
Run the following commands:

```
apicup certs get mgmt_dallas encryption-secret -t key > mgmt-encryption-secret

apicup certs set mgmt_raleigh encryption-secret mgmt-encryption-secret
```

8. Check that the management encryption key is set the same on both DC1 and DC2.
Run the following commands, and verify that the outputs match:

```
apicup certs get mgmt_dallas encryption-secret -t key

apicup certs get mgmt_raleigh encryption-secret -t key
```

9. Complete the remainder of the steps in Preparing the management subsystem for deployment from step 18 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
10. Complete the steps in Preparing the portal subsystem for deployment up to and including step 21 to create a portal subsystem in Raleigh (DC2).
11. Configure the 2DCDR values to set Raleigh to be warm-standby for the portal subsystem on DC2.
Run the following commands:

```
apicup subsys set port_raleigh multi-site-ha-enabled=true

apicup subsys set port_raleigh multi-site-ha-mode=passive

apicup certs set port_raleigh portal-replication-ingress --clear

apicup subsys set port_raleigh portal-replication=ptlreplicationraleigh.cluster2.example.com

apicup subsys set port_raleigh replication-peer-fqdn=ptlreplicationdallas.cluster1.example.com

apicup subsys set port_raleigh site-name=raleigh
```

where
   - ***port_raleigh*** is the name of the portal subsystem that you are configuring.
   - ***ptlreplicationraleigh.cluster2.example.com*** is the ingress hostname for the current data center in the two data center deployment.
   - ***ptlreplicationdallas.cluster1.example.com*** is the ingress hostname for the other data center in the two data center deployment.
   - ***raleigh*** is the name of the site in the current data center.

12. Run the following command to generate the default portal certificates on the warm-standby site:

```
apicup certs generate port_raleigh
```

13. Copy the encryption key for the portal subsystem on DC1 over to the portal subsystem on DC2.
    Run the following command to get the encryption key for the portal subsystem on DC1, and put it into a file that is called port-encryption-secret:

    ```
    apicup certs get port_dallas encryption-secret -t key > port-encryption-secret
    ```

    Run the following command to use the port-encryption-secret file to set the same encryption key on DC2:

    ```
    apicup certs set port_raleigh encryption-secret port-encryption-secret
    ```

    Where ***port_dallas*** is the name of the portal subsystem on DC1, and ***port_raleigh*** is the name of the portal subsystem on DC2.
    To check that the encryption key is set the same on both DC1 and DC2, you can run the following commands and verify that the outputs match:

    ```
    apicup certs get port_dallas encryption-secret -t key
    ```

    ```
    apicup certs get port_raleigh encryption-secret -t key
    ```

14. Complete the remainder of the steps in Preparing the portal subsystem for deployment from step 21 to verify that the configuration settings are valid, create your ISO file, and deploy the OVF template.
15. Check the status of the installation by running:

    ```
    apicup subsys status subsystem_name
    ```

16. Set your dynamic router to direct all traffic to DC1. The endpoints that must be directed to DC1 are:

Management subsystem endpoints
- `platform-api`
- `consumer-api`
- `cloud-admin-ui`
- `api-manager-ui`
- `consumer-catalog-ui`

Portal subsystem endpoints
- `portal-admin`
- `portal-www`

- **Validating your two data center deployment**
  Use the `apicup health-check` command to confirm that the management subsystems are ready and synchronized:

  ```
  apicup subsys health-check <management subsystem>
  ```

  If the management subsystem is healthy, the `health-check` command returns silently with no output.
  If you want to see more information in the `health-check` output, add the `-v` flag:

  ```
  apicup subsys health-check <management subsystem> -v
  ```

  ```
  ok(true) - Expected apicup version(10.0.8.0) to match apic version(10.0.8.0)
  ...
  ok(true) - ManagementCluster (specified multi site ha mode: active, current ha mode: active, ha status: Ready, ha message:
  Active DB is ready) is Ready | State: 17/17 | Phase: Running | Message: All services ready. HA status Ready - see HAStatus
  in CR for details
  ```

Example

Example of the management subsystem values that you can view by running the `apicup subsys get mgmt_name` command:

```
apicup subsys get mgmt_dallas
```

```

Related concepts

- Maintaining a two data center deployment

Upgrading API Connect

Upgrade API Connect on VMware to a newer version.

Upgrading your API Connect deployment consists of three phases:

1. Upgrade planning. Decide on your upgrade path based on your current version.

   Review any feature changes in the new API Connect version that might impact how you use API Connect and plan for such changes.

   Upgrade planning should be started as early as possible to identify any issues that might influence when you are able to upgrade, and any actions to take before upgrade.

2. Upgrade preparation. Run pre-upgrade checks on your current deployment, download the new version of API Connect from Fix Central, backup your current deployment.

   Upgrade preparation can be done at any time, and it is worth doing early to identify and fix any potential problems before your upgrade window. If you do complete the upgrade preparation early, repeat the pre-upgrade checks just before your upgrade window to check for any new problems.

3. Upgrade process. Updating your API Connect subsystems to the new version.

   The upgrade process should be started only when all upgrade planning and preparation are completed. Interrupting and rolling back API Connect upgrades is not possible. Disaster recovery procedures must be followed to restore API Connect to the old version if problems are encountered during upgrade.

Use the procedures in this section to upgrade API Connect on VMware.

Note: For information about how to maintain a two data center deployment, including upgrade considerations, see Maintaining a two data center deployment.

- **Planning your API Connect upgrade on VMware**
  Before you upgrade API Connect on VMware, check that your deployment meets all the upgrade requirements.
- **Pre-upgrade preparation and checks VMware**
  Prepare your VMware deployment for upgrading to the newest version of API Connect.
- **Upgrading management, portal, and analytics on VMware**
  Upgrade your management, portal, and analytics subsystems on VMware.
- **Upgrading DataPower Gateway**
  Use these instructions to upgrade your DataPower Gateway services in a non-Kubernetes environment.
- **Troubleshooting upgrades on VMware**
  Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on VMware.

Planning your API Connect upgrade on VMware

Before you upgrade API Connect on VMware, check that your deployment meets all the upgrade requirements.

Supported upgrade paths

Table 1 lists the supported upgrade paths for API Connect and explains whether a direct upgrade is supported or an interim upgrade is required.

Table 1. Supported upgrade paths

Upgrade from:	How to upgrade to 10.0.8.2-ifix1
10.0.8.1 10.0.8.0 10.0.5.8	Note: Before upgrading to APIC v10.0.8.2-ifix1, you must run the `apicops pre-upgrade` command to check for: • Encryption-related issues • Invalid gateway-extensions Complete the procedures in Pre-upgrade preparation and checks VMware and Upgrading management, portal, and analytics on VMware.
10.0.7.0	Upgrade to 10.0.8.0 first.

Upgrade from:	How to upgrade to 10.0.8.2-ifix1
10.0.5.7 and earlier 10.0.5 fix packs.	Upgrade to 10.0.5.8 first, as explained in Upgrading API Connect in the API Connect 10.0.5.x documentation. Note: To upgrade to API Connect 10.0.8.2-ifix1, you must first upgrade to 10.0.5.8 or later versions.
10.0.6.0	Upgrade to 10.0.7.0, then to 10.0.8.0 first. Make sure to perform the additional steps to preserve and re-create your SFTP backup configuration: 1. Upgrade to version 10.0.7.0 as explained in Upgrading management, portal, and analytics on VMware in the API Connect 10.0.7.0 documentation. If you used SFTP backups in 10.0.6.0, enable the **`accept-no-backups`** parameter as explained in the upgrade instructions. SFTP is not supported in 10.0.7.0 but you can configure SFTP backups after the upgrade to the new release is complete. 2. Upgrade to 10.0.8.0. Note: To upgrade to API Connect 10.0.8.2-ifix1, you must first upgrade to 10.0.8.0 or later versions. 3. Upgrade to the current release by completing the procedures in Upgrading management, portal, and analytics on VMware.

Supported DataPower Gateway versions

You can use any combination of API Connect 10.0.8.x with DataPower 10.6.0.y.

Before you upgrade, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. When you find the information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

Control planes for upgrading to 10.0.8.2-ifix1

API Connect 10.0.8.2-ifix1 installs with **`appliance-control-plane-1.31.x.tgz`**.

Table 2. Control Plane files needed for upgrading to 10.0.8.2-ifix1

Upgrading from API Connect version	Control Plane files needed
10.0.8.1	No Control Plane needed.
10.0.8.0	• **`appliance-control-plane-1.30.x.tgz`** • **`appliance-control-plane-1.29.x.tgz`**
10.0.5.8	No Control Plane needed.

Upgrade requirements

- API Connect is not supported on a FIPS-enabled environment.
- The instructions for upgrading apply to the latest version of API Connect.
- The upgrade order for subsystems is important. Upgrade the subsystems in the following order:
  1. Management
  2. Portal
  3. Analytics
  4. Gateway

  Gateway must be upgraded after management so that any new policies and capabilities are available to any previously registered gateway services.
  Note:
  - When maintaining API Connect, do not use **`kubectl exec`** commands to access API Connect pods unless advised by IBM.
  - Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

Important upgrade considerations

Carefully review the following items, to plan and prepare for your upgrade.

Upgrade to V10.0.8.1 and later: Ubuntu Linux upgrade
: Before upgrading to V10.0.8.1, the Ubuntu Linux version on each VM must be updated from 20.04 to 22.04 and your API Connect deployment must be on 10.0.5.8 or 10.0.8.0. If your API Connect version is older than 10.0.8.1 and you want to upgrade to 10.0.8.1 or later versions, you must first upgrade to 10.0.8.0 or 10.0.5.8 before upgrading the Ubuntu Linux version. The Linux upgrade is done in step 2 of the upgrade procedure.

Upgrade to V10.0.8.0: Analytics database backup changes
: New analytics database backup functionality is added in V10.0.8. This change means that it is not possible to restore pre-V10.0.8 analytics database backups to a V10.0.8 analytics subsystem.

V10.0.8 requires x86-64-v2 CPU microcode support
: Your API Connect VMs must have a CPU architecture that supports x86-64-v2. You can verify your existing API Connect VMs with the following steps:

  1. Run the mustgather script on your API Connect VMs.
  2. Check the output of the mustgather script for:

     ```
     [YYYY-MM-DD HH:MM:SS] INFO - VM CPU might not support x86-64-v2
     ```

  If your VMs do not support x86-64-v2, then check with your VMware administrator before you upgrade. You might need to redeploy API Connect on VMs that do support it, following the disaster recovery procedures: Disaster recovery.

Extra storage required for analytics local backups
: If analytics database backups are configured, then beginning with V10.0.8.0 an extra PV is required to store local backups and prepare them for transmission to your remote SFTP server or object-store.

Before you upgrade, verify that you have sufficient disk space on your analytics VMs and increase it if necessary: Adding disk space to a VMware appliance. To estimate storage requirements for your local backups, see Estimating storage requirements.

OAuth provider resources with `api.securityDefintions`

If you have native OAuth providers that are configured with the `api.securityDefintions` field assigned, then upgrade fails. Before upgrade, remove all `api.securityDefintions` from all native OAuth providers that you configured in the Cloud Manager and API Manager UIs:

- Configuring a native OAuth provider in the Cloud Manager UI
- Configuring a native OAuth provider in the API Manager UI

Switch to the source view and delete any `securityDefintions` sections that are present.

Extra backup folder appended to management database backup path

When you upgrade to V10.0.7.0 or later with S3 backups configured, an extra backup path folder /edb is appended to your backup path. The /edb path distinguishes new EDB backups from your previous management backups.

Pre-upgrade preparation and checks VMware

Prepare your VMware deployment for upgrading to the newest version of API Connect.

Before you begin

Review the Planning your API Connect upgrade on VMware to ensure that you are following a supported upgrade path and that you understand important changes that might affect your deployment.

Procedure

VM health checks:

1. From your project directory, run the **apicup** health-check command for each of your subsystems.

   ```
   apicup subsys health-check <subsystem name>
   ```

   If the health check is successful, then the command returns silently.

   If you see an IO timeout error, then it's likely that a firewall is blocking access to port 9178. For example:

   ```
   apicup subsys health-check <subsystem name>
   ...
   Error: failed to install the subsystem: unable to open file send stream:
    rpc error: code = Unavailable desc = all SubConns are in TransientFailure,
    latest connection error: connection error:
    desc = "transport: Error while dialing dial tcp 1.2.3.4:9178: i/o timeout"
   ```

   If you see this error, make sure that your firewall has port 9178 open.

2. Login to each of your API Connect VMs and switch to the root user:

   ```
   ssh apicadm@<hostname>
   ```

   ```
   sudo -i
   ```

3. Delete any stale upgrade files that might be left on the VM from previous upgrades:

   ```
   apic clean-upgrade-files
   ```

4. Remove obsolete `sources` files to ensure a clean upgrade.
   Delete any files in the directory /etc/apt/sources.list.d whose names match the format: repo-*<subsystem>*-*<version>*-*<appliance version>*.list:

   ```
   rm /etc/apt/sources.list.d/repo-*.list
   ```

5. Verify that each VM has sufficient disk space:
   a. Check the available space on the data disk:

      ```
      df -h /data/secure
      ```

      If disk usage is higher than 70%, then add disk capacity. See Adding disk space to a VMware appliance.

   b. Check available space in "/":

      ```
      df -h /
      ```

      If disk usage is higher than 70%, delete or copy off older `/var/log/syslog*.gz` files. The `syslog` files contain your API Connect and system logs. Do not delete any syslog files that might contain log data that is needed for any active support cases. If in doubt, backup the syslog files to another system before your delete them.

6. Run the **apicops** pre-upgrade health checks:
   a. Download the latest apicops release and copy it to your VM.
   b. Run the **apicops** pre-upgrade check on your API Connect VMs:
   Note: If you have a three replica deployment, then run this check on just one VM from each subsystem.
      i. Management VM:

         ```
         apicops system:pre-upgrade-check management
         ```

         Note: If you have a 2DCDR deployment, run this check only on the active management subsystem.

Before upgrading, run the following command to check for encryption issues and invalid gateway extensions:

For a full check (requires admin password to verify topology):

```
apicops preupgrade -n <namespace>
```

To skip topology verification (no admin password needed):

```
apicops preupgrade --no-topology -n <namespace>
```

ii. Portal VM:

```
apicops system:pre-upgrade-check portal
```

iii. Analytics VM:

```
apicops system:pre-upgrade-check analytics
```

If the pre-upgrade check returns any errors, then collect the output and open a support case.

Pre-upgrade backups and preparation:

7. Optional: Set up remote logging: Configuring remote logging for a VMware deployment.
   If the upgrade process fails, it is possible that important log messages for problem diagnosis are not retained on the VMs. Configure remote logging to ensure that all API Connect logging during the upgrade is retained.

8. Backup all your subsystems. Ensure that you have:
   - Database backups of all your subsystems.
   - Project directory backup.
   - **Optional:** VM snapshots of all subsystems.

   Upgrading from V10.0.7.0 : see Backing up and restoring on VMware.

   Upgrading from V10.0.5.x: see Backing up and restoring on VMware.

Download and verify the API Connect upgrade files:

9. Obtain the API Connect upgrade files:
   You can access the latest files from IBM Fix Central by searching for the API Connect product and your installed version.

   The following files are used during upgrade on VMware:

   IBM API Connect *<version>* Management Upgrade File for VMware
   : Management subsystem files for upgrade. Filename is: upgrade_management_*<version>*.

   IBM API Connect *<version>* Developer Portal Upgrade File for VMware
   : Developer Portal subsystem files for upgrade. Filename is: upgrade_portal_*<version>*

   IBM API Connect *<version>* Analytics Upgrade File for VMware
   : Analytics subsystem files for upgrade. Filename is upgrade_analytics_*<version>*

   IBM API Connect *<version>* Install Assist for *<operating_system_type>*
   : The apicup installation utility. Required for all installations on VMware. Filename is apicup-*<platform>*_*<version>*.

   ubuntu-jammy-upgrade.tgz
   : The ubuntu-jammy-upgrade.tgz is required for upgrade to V10.0.8.1. The file contains the Ubuntu Linux upgrade packages which must be applied before the API Connect upgrade.

   IBM® API Connect *<version>* Security Signature Bundle File
   : Signature files for verifying the integrity of your downloads.
   Filename is signatures_*<version>*.

   The following files are not used during the upgrade process, but should be downloaded to replace your existing versions of them:

   IBM API Connect *<version>* Toolkit for *<operating_system>*
   : Toolkit command-line utility. Packaged as a stand-alone file, or with API Designer:
     - IBM® API Connect *<version>* Toolkit for *<operating_system>*
     - IBM® API Connect *<version>* Toolkit Designer for *<operating_system>*

   Filename is toolkit-...*<operating system>*_*<version>*.
   Not required during initial installation. After installation, you can download directly from the Cloud Manager UI and API Manager UI as explained in Installing the toolkit.

   IBM API Connect *<version>* Local Test Environment
   : Optional test environment for testing locally as explained in Testing an API with the Local Test Environment.
   Filename is apic-lte-*<operating system>*_*<version>*.

10. If control plane files are required for your upgrade path, download them from the same IBM Fix Central page.
    Control plane files are required to support specific Kubernetes versions. The IBM API Connect *<version>* Management Upgrade File for VMware file contains the latest control plane file.

    Table 1 lists the control plane files that are needed for upgrading to the current release.

    Tip: On the Fix Central page, type "control-plane" in the Filter fix details field to list only the control plane files in the results table. Then, click the Description header to sort the results so you can easily locate the control plane files that you need.

    Table 1. Control Plane files needed for upgrading to 10.0.8.0

Upgrading from API Connect version	Control Plane files needed
• 10.0.7.0 • 10.0.5.7 • 10.0.5.6 • 10.0.5.5	No Control Plane needed.

Upgrading from API Connect version	Control Plane files needed
• 10.0.5.4	Download: • `appliance-control-plane-1.27.x.tgz`

For information about the control plane files that are required for upgrading to older releases as interim steps, see Control Plane files for earlier releases.

11. Complete the steps in Verifying the integrity of IBM product files to verify that the downloaded product files are not corrupted.
12. Set up the new **apicup** command in your project directory.
    The **apicup** executable file is updated with each API Connect release. To upgrade API Connect, you must replace the **apicup** file from your current release with the new **apicup** file.
    Note: If you decide to stop or delay your API Connect upgrade, then revert these steps.
    a. In your project directory, take a backup of your current apicup file, appending the current API Connect version to the name of the backup file.
    For example:

    ```
    cp apicup apicup_v10.0.7.0
    ```

    b. Replace the apicup file in your project directory with the new apicup file that you downloaded in step 9.
    c. macOS and Linux® only: Make the apicup file executable:

    ```
    chmod +x apicup
    ```

    d. Set your operating system's **PATH** variable to include your project directory:

    Table 2. Commands for setting the path to the apicup file

Operating system	Command to set the path
macOS and Linux	`export PATH=$PATH:<project directory path>`
Windows	`set PATH=<project directory path>;%PATH%`

    e. Verify that the new **apicup** command is in your **PATH**, run:

    ```
    apicup version
    ```

    The output should show the version that you are upgrading to.

    f. Run the **apicup** command to accept the API Connect license:

    ```
    apicup licenses accept <License ID>
    ```

    <License ID> is specific to the API Connect Program Name that you purchased. To view the supported license IDs, see API Connect licenses.

- **Control Plane files for earlier releases**
  If you are upgrading to an earlier version than 10.0.8.2-ifix1 as an interim step, refer to the following tables to determine which Control Plane files are required.

Control Plane files for earlier releases

If you are upgrading to an earlier version than 10.0.8.2-ifix1 as an interim step, refer to the following tables to determine which Control Plane files are required.

Control planes for upgrading to 10.0.8.2-ifix1

API Connect 10.0.8.2-ifix1 installs with **appliance-control-plane-1.31.x.tgz**.

Table 1. Control Plane files needed for upgrading to 10.0.8.2-ifix1

Upgrading from API Connect version	Control Plane files needed
10.0.8.1	No Control Plane needed.
10.0.8.0	• `appliance-control-plane-1.30.x.tgz` • `appliance-control-plane-1.29.x.tgz`
10.0.5.8	No Control Plane needed.

Control planes for upgrading to 10.0.8.1

API Connect 10.0.8.1 installs with **appliance-control-plane-1.30.x.tgz**

Table 2. Control Plane files needed for upgrading to 10.0.8.1

Upgrading from API Connect version	Control Plane files needed
10.0.8.0	`appliance-control-plane-1.29.x.tgz`
10.0.5.8	No Control Plane needed.

Control planes for upgrading to 10.0.8.0

Installs with **appliance-control-plane-1.28.x.tgz**

Table 3. Control Plane files needed for upgrading to 10.0.8.0

Upgrading from API Connect version	Control Plane files needed
• 10.0.7.0 • 10.0.5.7 • 10.0.5.6 • 10.0.5.5	No Control Plane needed.

Upgrading from API Connect version	Control Plane files needed
• 10.0.5.4	Download: • `appliance-control-plane-1.27.x.tgz`

Control planes for upgrading to 10.0.7.0

Installs with `appliance-control-plane-1.27.x.tgz`

Table 4. Control Plane files needed for upgrading to 10.0.7

Upgrading from API Connect version	Control Plane files needed
• 10.0.6.0 • 10.0.5.5 • 10.0.5.4 • 10.0.5.3	No Control Plane needed.

Control planes for upgrading to 10.0.5.7

Installs with `appliance-control-plane-1.28.x.tgz`

Table 5. Control Plane files needed for upgrading to 10.0.5.6

API Connect version	Control Plane files needed
• 10.0.5.6 • 10.0.5.5 • 10.0.5.4 • 10.0.5.3 • 10.0.1.15-eus • 10.0.1.12-eus	No control-plane file needed.

Control planes for upgrading to 10.0.5.6

Installs with `appliance-control-plane-1.27.x.tgz`

Table 6. Control Plane files needed for upgrading to 10.0.5.6

API Connect version	Control Plane files needed
• 10.0.5.5 • 10.0.5.4 • 10.0.5.3 • 10.0.1.15-eus • 10.0.1.12-eus	No control-plane file needed.
• 10.0.5.2 • 10.0.1.11-eus • 10.0.1.9-eus	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz`
• 10.0.5.1 • 10.0.1.8-eus • 10.0.1.7-eus	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz`
• 10.0.4.0 and iFixes	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz` • `appliance-control-plane-1.23.x.tgz`
• 10.0.3.0 and iFixes • 10.0.1.6-eus and iFixes • 10.0.1.5-eus and iFixes • 10.0.1.4-eus and iFixes	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz` • `appliance-control-plane-1.23.x.tgz` • `appliance-control-plane-1.22.x.tgz`

API Connect version	Control Plane files needed
• 10.0.2.0 • 10.0.1.2-eus and iFixes	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz` • `appliance-control-plane-1.23.x.tgz` • `appliance-control-plane-1.22.x.tgz` • `appliance-control-plane-1.21.x.tgz`

Control planes for upgrading to 10.0.5.5

Installs with `appliance-control-plane-1.27.x.tgz`

Table 7. Control Plane files needed for upgrading to 10.0.5.5

API Connect version	Control Plane files needed
• 10.0.5.4 • 10.0.5.3 • 10.0.1.15-eus • 10.0.1.12-eus	No control-plane file needed.
• 10.0.5.2 • 10.0.1.11-eus • 10.0.1.9-eus	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz`
• 10.0.5.1 • 10.0.1.8-eus • 10.0.1.7-eus	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz`
• 10.0.4.0 and iFixes	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz` • `appliance-control-plane-1.23.x.tgz`
• 10.0.3.0 and iFixes • 10.0.1.6-eus and iFixes • 10.0.1.5-eus and iFixes • 10.0.1.4-eus and iFixes	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz` • `appliance-control-plane-1.23.x.tgz` • `appliance-control-plane-1.22.x.tgz`
• 10.0.2.0 • 10.0.1.2-eus and iFixes	Download: • `appliance-control-plane-1.26.x.tgz` • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz` • `appliance-control-plane-1.23.x.tgz` • `appliance-control-plane-1.22.x.tgz` • `appliance-control-plane-1.21.x.tgz`

Control planes for upgrading to 10.0.5.4

Installs with `appliance-control-plane-1.26.x.tgz`

Table 8. Control Plane files needed for upgrading to 10.0.5.4

API Connect version	Control Plane files needed
• 10.0.5.3 • 10.0.1.12-eus	No control-plane file needed.
• 10.0.5.2 • 10.0.1.11-eus • 10.0.1.9-eus	Download: • `appliance-control-plane-1.25.x.tgz`
• 10.0.5.1 • 10.0.1.8-eus • 10.0.1.7-eus	Download: • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz`

API Connect version	Control Plane files needed
• 10.0.4.0 and iFixes	Download: • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz` • `appliance-control-plane-1.23.x.tgz`
• 10.0.3.0 and iFixes • 10.0.1.6-eus and iFixes • 10.0.1.5-eus and iFixes • 10.0.1.4-eus and iFixes	Download: • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz` • `appliance-control-plane-1.23.x.tgz` • `appliance-control-plane-1.22.x.tgz`
• 10.0.2.0 • 10.0.1.2-eus and iFixes	Download: • `appliance-control-plane-1.25.x.tgz` • `appliance-control-plane-1.24.x.tgz` • `appliance-control-plane-1.23.x.tgz` • `appliance-control-plane-1.22.x.tgz` • `appliance-control-plane-1.21.x.tgz`

Upgrading management, portal, and analytics on VMware

Upgrade your management, portal, and analytics subsystems on VMware.

Before you begin

- Review Planning your API Connect upgrade on VMware.
- Complete the Pre-upgrade preparation.
- Enable keep-alive in your SSH client configuration to avoid disconnects during the transfer of the upgrade images to your VMs. For more information, consult the documentation for the version of SSH that is installed on your client system (where you run the **apicup** commands from).
- If you have a two data center disaster recovery deployment, read and understand the extra requirements for this deployment type: Upgrading a two data center deployment.

About this task

- The upgrade order for subsystems is important. Upgrade the subsystems in the following order: (1) management, (2) portal, (3) analytics, (4) gateway. Management must be upgraded first to ensure that any new policies and capabilities are available to previously registered gateway services.
- When you start the upgrade process on a subsystem, the **apicup install** command sends the compressed upgrade files to all subsystem VMs. The compressed files are about 2 GB, and the transfer can take some time. The **apicup install** command exits when the transfer of the upgrade files to each VM is complete, at which point the upgrade starts. The progress of the upgrade is monitored with other commands.
- The `apicup subsys install` command runs `apicup health-check` first before the upgrade process is started. If the health-check fails, then the upgrade is aborted and details of the health-check failure is displayed.
  If you are troubleshooting a problem with upgrade and want the upgrade to proceed despite a health-check failure, then you can suppress the health check. See Skipping health check when re-running upgrade.
- You do not need to upgrade the components API Connect Toolkit and API Connect Local Test Environment in the same upgrade window. These components are single executable files. Replace them the new versions downloaded from Fix Central.
- If any subsystem database backups are running or are scheduled to run within a few hours, do not start the upgrade process.
- Do not perform maintenance tasks such as updating certificates, restoring subsystem databases from backup, or triggering subsystem database backups at any time while you are upgrading API Connect.

Procedure

1. If some time has passed since you completed the Pre-upgrade preparation, repeat these pre-upgrade steps to be sure that your subsystems are ready for upgrade.
2. Upgrade Ubuntu Linux on all VMs from 20.04 to 22.04.
   Note:
   - Skip this step if you are on API Connect 10.0.8.1 or later or 10.0.5.9 and later. If you are on older versions, you must first upgrade your API Connect deployment to 10.0.5.8 or 10.0.8.0 before attempting to upgrade.
   - It is strongly recommended to upgrade your API Connect product version immediately after upgrading Ubuntu. IBM generally supports one operating system (OS) version per product version. Prolonged use of an unsupported OS/product version pair may result in unexpected behavior, security vulnerabilities, or lack of support.

   a. On all API Connect subsystems, run the following command:

   ```
   apicup subsys prepare-ubuntu-upgrade <subsystem name> ubuntu-jammy-upgrade.tgz
   ```

   This command copies the Ubuntu Linux upgrade package to all subsystem VMs.

   Note: If you face any problems during upgrade, see Ubuntu preupgrade failures during OVA upgrade from 10.0.8.0 to 10.0.8.1.

   b. Login to each VM:

   ```
   ssh apicadm@<subsystem VM>
   ```

   c. Run the following commands:

Note: Run the commands mentioned in the steps 2c(i) and 2c(ij) only if you are upgrading to 10.0.8.1. Skip these steps if you are upgrading to a later version.

i. `sudo sed -i '/sudo \/usr\/local\/lib\/record\/proxy/icd \/usr\/local\/lib\/record' /usr/local/bin/record-proxy.sh`

ii. `sudo systemctl restart record-proxy`

iii. `sudo apt update`

iv. `sudo apt upgrade`

v. `sudo apt dist-upgrade`

vi. `sudo do-release-upgrade`

vii. If you see the message:

```
You have not rebooted after updating a package which requires a reboot. Please reboot before upgrading.
```

then:

1. Run the following command:

   ```
   sudo apic lock
   ```

2. Reboot the VM:

   ```
   sudo reboot
   ```

3. From the project directory, verify VM is up with:

   ```
   apicup subsys health-check <subsystem name>
   ```

   No output means the health check passed.

4. Login to the VM and to complete the upgrade re-run:

   ```
   sudo do-release-upgrade
   ```

viii. Verify Ubuntu upgrade is complete:

```
sudo lsb_release -a
```

The output should be:

```
No LSB modules are available.
Distributor ID: Ubuntu
Description:    Ubuntu 22.04.4 LTS
Release:        22.04
Codename:       jammy
```

d. After Ubuntu is upgraded on all the API Connect VMs, check the subsystem health:

```
apicup subsys health-check <subsystem name>
```

No output means the health check passed.

If asked to reboot, then:

i. Run the following command:

```
sudo apic lock
```

ii. Reboot the VM:

```
sudo reboot
```

e. From the project directory, cleanup the Ubuntu upgrade packages:

```
apicup subsys cleanup-ubuntu-upgrade <subsystem name>
```

3. Block all external traffic to the management server.
Upgrading API Connect requires downtime while files are transferred and updated. All external traffic to the management server from all sources (Cloud Manager UI, API Manager UI, CLI, and REST API) must be blocked. As a result, the Cloud Manager and API Manager UIs cannot be used during the upgrade. In addition, the developer portal cannot be used to create, update, or delete any applications, subscriptions, memberships, or consumer organizations during the upgrade.

4. Verify that the new **apicup** command is in your operating system's `PATH` variable:

```
apicup version
```

The version that is returned should be the version that you are upgrading to. If not, then refer to step 12 on Pre-upgrade preparation and checks VMware.

5. Upgrade the management subsystem:

a. **Upgrading 10.0.7.0 only:** If you are upgrading from 10.0.7.0 to 10.0.8.0, enable maintenance mode for the Management subsystem:

i. SSH into a Management node and then log in as `root`.

ii. Run the following command:

```
kubectl-cnp maintenance set --reusePVC
```

When the upgrade is complete, maintenance mode is automatically disabled.

Attention: Failing to enable maintenance mode results in the following error:

```
# ./apicup subsys install kqn3-management ../repo-management.tgz --debug
DEBU[0000] Found PDB kqn3-management-site1-db
```

```
DEBU[0000] Found PDB kqn3-management-site1-db-primary
Error: Unable to upgrade: EDB node maintenance mode has not been enabled.
```

b. Optional: **If upgrading from 10.0.5.x or 10.0.7.0:** Provide a custom endpoint for the Consumer Catalog.
Skip this step if you are upgrading from 10.0.8.0 or later.

Beginning with version 10.0.8.0, API Connect includes the Consumer Catalog feature. During the upgrade from 10.0.5.x or 10.0.7.0, a new endpoint is added to the management subsystem for the Custom Catalog. The new endpoint uses a default host name and certificate based on the values used for other management endpoints. If you want to change the values for the Consumer Catalog, complete the following steps before running the management upgrade.

i. Change the host name for the Consumer Catalog endpoint by running the following command:

```
apicup subsys set <management_subsystem_name> consumer-catalog-ui=${consumer_catalog_endpoint}
```

Attention: If you changed the host name, then you must also complete the next step to change the certificate.

ii. Regenerate the `consumer-catalog-ui` certificate by running the following commands:

```
apicup certs set --clear <management_subsystem_name> consumer-catalog-ui
apicup certs generate <management_subsystem_name>
```

c. Start the upgrade of the management subsystem:
Attention: If you are upgrading a two data center disaster recovery deployment, upgrade the warm-standby data center first.
For more information about two data center disaster recovery upgrade, see Upgrading a two data center deployment.

i. Login in to each VM of the management subsystem as root and run the following command:

```
for pkg in libpq5 shim shim-signed; do rm -f "/etc/apt/preferences.d/${pkg}-preferences"; done
```

Note: This step ensures a clean upgrade environment by removing any outdated package preferences from a previous upgrade (For example, v10.0.8.1).

ii. Install the management subsystem upgrade file. The arguments to include in the install command depend on your upgrade path and configuration:

- Single data center deployment and upgrading from V10.0.5.x:

```
apicup subsys install <subsystem name> <subsystem_upgrade_tar_archive> --force-operand-update
```

- Single data center deployment and upgrading from V10.0.7.0 or later:

```
apicup subsys install <subsystem name> <subsystem_upgrade_tar_archive>
```

- Two data center disaster recovery deployment and upgrading warm-standby data center from V10.0.5:

```
apicup subsys install <subsystem name> <subsystem_upgrade_tar_archive> --accept-warm-standby-upgrade-data-deletion --skip-health-check --force-operand-update
```

- Two data center disaster recovery deployment and upgrading active data center from V10.0.5.x:

```
apicup subsys install <subsystem name> <subsystem_upgrade_tar_archive> --skip-health-check --force-operand-update
```

- Two data center disaster recovery deployment and upgrading warm-standby data center from V10.0.7 or later:

```
apicup subsys install <subsystem name> <subsystem_upgrade_tar_archive>
```

- Two data center disaster recovery deployment and upgrading active data center from V10.0.7.0 or later:

```
apicup subsys install <subsystem name> <subsystem_upgrade_tar_archive>
```

Note: If you are including one or more control plane files, specify the file path to each control plane file (separate multiple file paths with blank spaces); for example:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1> <path_to_control_plane_file_n> <other arguments>
```

iii. Verify that the upgrade was successful by running the **apicup** health check:

```
apicup subsys health-check <subsystem_name>
```

Troubleshooting: If health-check reports any problems, then see Troubleshooting upgrades on VMware.
Note: Two data center disaster recovery deployments: After upgrading the warm-standby management subsystem, the health-check reports a status of Blocked until the active management subsystem is upgraded, see step 5.d.

iv. If the health check indicates that a reboot is needed, complete the following steps on all management VMs:

1. Log in to the VM:

```
ssh apicadm@<hostname>
```

2. Switch to `root` user:

```
sudo -i
```

3. `systemctl reboot`

d. Two data center disaster recovery deployments: If you just upgraded the warm-standby data center, then complete the following checks before you start the upgrade on the active data center:
Check the warm-standby management subsystem status with the following command:

```
apicup subsys health-check <management warm-standby>
```

If the output of the command is:

```
ManagementCluster (specified multi site ha mode: passive, current ha mode: WarmStandbyError, ha status: Error, ha message: Remote HAMode is Empty (Not received from peer). Expected it to be in either active or setup complete phase)
```

```
is not Ready or Complete | State: 2/18 | Phase: Blocked | Message: HA status Error - see HAStatus in CR for details
Spec version <target version> and reconciled version <source version> do not match
```

then you can proceed to upgrade the management subsystem in the active data center.

6. If you have multiple management subsystems in the same project, set the portal subsystem's **platform-api** and **consumer-api** certificates to match the certificates used by their corresponding management subsystems.
   Note: Complete this step only if you installed more than one management subsystem into a single project.
   A portal subsystem can be associated with only one management subsystem. To associate the upgraded portal subsystem with the appropriate management subsystem, manually set the **mgmt-platform-api** and **mgmt-consumer-api** certificates to match the ones used by the management subsystem.

   a. Run the following commands to get the certificates from the management subsystem:

   ```
   apicup certs get mgmt-subsystem-name platform-api -t cert > platform-api.crt
   apicup certs get mgmt-subsystem-name platform-api -t key > platform-api.key
   apicup certs get mgmt-subsystem-name platform-api -t ca > platform-api-ca.crt

   apicup certs get mgmt-subsystem-name consumer-api -t cert > consumer-api.crt
   apicup certs get mgmt-subsystem-name consumer-api -t key > consumer-api.key
   apicup certs get mgmt-subsystem-name consumer-api -t ca > consumer-api-ca.crt
   ```

   where *mgmt-subsystem-name* is the name of the specific management subsystem that you want to associate the new portal subsystem with.

   b. Run the following commands to set the portal's certificates to match the certificates used by the management subsystem:

   ```
   apicup certs set ptl-subsystem-name platform-api Cert_file_path Key_file_path CA_file_path

   apicup certs set ptl-subsystem-name consumer-api Cert_file_path Key_file_path CA_file_path
   ```

7. Upgrade the portal subsystem.
   Attention: If you are upgrading a two data center disaster recovery deployment, upgrade the warm-standby data center first.
   For more information about two data center disaster recovery upgrade, see Upgrading a two data center deployment.

   a. Login in to each VM of the portal subsystem as root and run the following command:

   ```
   for pkg in libpq5 shim shim-signed; do rm -f "/etc/apt/preferences.d/${pkg}-preferences"; done
   ```

   Note: This step ensures a clean upgrade environment by removing any outdated package preferences from a previous upgrade (For example, v10.0.8.1).

   b. Install the portal subsystem upgrade file. The arguments to include in the install command depend on your upgrade path and configuration:

   - Single data center deployment:

     ```
     apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
     ```

   - Two data center disaster recovery deployment. The portal subsystem in the warm-standby data center:

     ```
     apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
     ```

   - Two data center disaster recovery deployment. The portal subsystem in the active datacenter:

     ```
     apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> --skip-health-check
     ```

     Note: The portal subsystem in the data center might appear in a non-READY state after the warm-standby is upgraded. This is expected, and the **--skip-health-check** argument tells the upgrade to proceed despite the non-READY state.

   Note: If you are adding one or more control plane files, specify the file path of each control plane file:

   ```
   apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1>
   <path_to_control_plane_file_n> <other arguments>
   ```

   c. Verify that the upgrade was successful by running a health check with the following command:

   ```
   apicup subsys health-check <subsystem_name>
   ```

   Important: If the health check indicates that a reboot is required, first complete the upgrade for all portal sites and verify that all sites were upgraded. Then run the reboot command at the end of this step.

   d. If the upgrade fails and the subsystem is in the **SUBSYSTEM_ROLLBACK** state, do not proceed with the upgrade.
   If the subsystem is in the **SUBSYSTEM_ROLLBACK** state, then the upgrade was automatically rolled back. Contact IBM Support for help resolving the underlying problem before attempting another upgrade. Refer to the troubleshooting section called Upgrade from V10.0.7 fails with an automatic rollback for instructions on performing a rollback and resolving the underlying problem before attempting the upgrade again.

   e. If you have two data center disaster recovery deployment and upgraded the portal subsystem in the warm-standby data center, then start the upgrade on the active data center.
   Note: In a two data center disaster recovery deployment, after the warm-standby is upgraded, the active data center might enter a non-READY state. If this happens, do not be concerned, proceed to upgrade the portal subsystem in the active data center.

8. Verify portal site upgrades are complete.

   a. Log in as an admin user:

   ```
   apic login -s <server_name> --realm admin/default-idp-1 --username admin --password <password>
   ```

   b. Get the portal service ID and endpoint:

   ```
   apic portal-services:get -o admin -s <management_server_endpoint> \
               --availability-zone availability-zone-default <portal-service-name> \
               --output - --format json
   ```

   c. List the sites:

   ```
   apic --mode portaladmin sites:list -s <management_server_endpoint> \
               --portal_service_name <portal-service-name> \
               --format json
   ```

   Any sites currently upgrading display the **UPGRADING** status; any site that completed its upgrade displays the **INSTALLED** status and the new platform version. Verify that all sites display the **INSTALLED** status before proceeding.

For more information about the **sites** command, see the toolkit CLI reference documentation.

d. After all sites are in **INSTALLED** state and show the new platform listed, run:

```
apic --mode portaladmin platforms:list -s <server_name> --portal_service_name <portal_service_name>
```

Verify that the new version of the platform is the only platform listed.

For more information about the **platforms** command, see the toolkit CLI reference documentation.

e. If all portal sites are upgraded and the health check indicates that a reboot is needed, then run the following command on all portal VMs:

```
systemctl reboot
```

9. Upgrade the analytics subsystem.
   a. Login in to each VM of the analytics subsystem as root and run the following command:

```
for pkg in libpq5 shim shim-signed; do rm -f "/etc/apt/preferences.d/${pkg}-preferences"; done
```

Note: This step ensures a clean upgrade environment by removing any outdated package preferences from a previous upgrade (For example, v10.0.8.1).

   b. Install the analytics subsystem files:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive>
```

Note: If you are adding one or more control plane files, specify the file path of each control plane file:

```
apicup subsys install <subsystem_name> <subsystem_upgrade_tar_archive> <path_to_control_plane_file_1>
<path_to_control_plane_file_n>
```

   c. Verify that the upgrade was successful by running a health check with the following command:

```
apicup subsys health-check <subsystem_name>
```

   d. If the upgrade fails and the subsystem is in the **SUBSYSTEM_ROLLBACK** state, do not proceed with the upgrade.
   If the subsystem is in the **SUBSYSTEM_ROLLBACK** state, then the upgrade was automatically rolled back. Contact IBM Support for help resolving the underlying problem before attempting another upgrade. Refer to the troubleshooting section called Upgrade from V10.0.7 fails with an automatic rollback for instructions on performing a rollback and resolving the underlying problem before attempting the upgrade again.

   e. If the health check indicates that a reboot is needed, run the following commands on all analytics VMs:

```
systemctl reboot
```

10. Take a backup of your project directory, and database backups of each upgraded API Connect subsystem; see Backing up and restoring on VMware.
11. Optional: Take a virtual machine (VM) snapshot of all your VMs; see Using VM snapshots for infrastructure backup and disaster recovery for details. This action requires a brief outage while the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully.

What to do next

When your management, portal, and analytics subsystem are upgraded, upgrade your DataPower Gateway service. See Upgrading DataPower Gateway.

Upgrading DataPower Gateway

Use these instructions to upgrade your DataPower Gateway services in a non-Kubernetes environment.

Before you begin

Complete the upgrade of the API Connect management, portal, and analytics subsystems before upgrading gateway. Upgrading the management subsystem before the gateway ensures that any new policies and capabilities are available to a previously registered gateway service.

About this task

- The DataPower Gateway Service in a non-Kubernetes environment can be on either a physical appliance or in a virtual DataPower deployment.
- The upgrade of DataPower Gateway Service in a non-Kubernetes environment, for use in API Connect deployments in a VMware environment, does not use the **apicup** command. Use DataPower Gateway instructions in the following steps.

Note: To upgrade the DataPower Gateway Service in a Kubernetes environment, do not use this procedure. Instead, see Upgrading the gateway subsystem on Kubernetes.

Procedure

1. Ensure that the DataPower Gateway firmware version you plan to install is compatible with the API Connect management subsystem version.
   Note:
   Before you install, best practice is to review the latest compatibility support for your version of API Connect. To view compatibility support, follow the instructions in IBM API Connect Version 10 software product compatibility requirements to access API Connect information on the Software Product Compatibility Reports website. Once you access information for your version of API Connect, select Supported Software > Integration Middleware, and view the list of compatible DataPower Gateway versions.

2. When you upgrade a high-availability cluster, check that you meet the following requirements:
   - Gateways must be updated one at a time.
   - Before you start the upgrade, a single gateway must be running as primary for all gateway-peering definitions.
   - If you are upgrading multiple gateways, the primary gateway must be upgraded last.

To determine which gateway is running as primary, use either the **`show gateway-peering-status`** command in the DataPower CLI, or use the Gateway Peering Status display in the Web GUI in the API Connect application domain. To move the primary to the DataPower on which you are working, you can issue the **`gateway-peering-switch-primary <peering-object-name>`** command.

3. Ensure that your deployment includes an NTP server to synchronize time between each of the DataPower Gateways. See Managing the NTP service.
4. Ensure that a unique **`System Identifier`** is set for each v10 DataPower Gateway . See Initializing the DataPower Gateway.
5. Follow the upgrade instructions on the DataPower Gateway documentation. See Installation operations.
   Note:
   - If you are upgrading a cluster (high-availability) deployment, ensure that you have identified which gateway is running a primary in gateway-peering definitions, and that you upgrade that gateway last.
   - For troubleshooting help with DataPower operator deployments, see IBM DataPower Operator documentation.

Upgrading a two data center deployment

How to upgrade a two data center disaster recovery (DR) deployment on VMware.

To upgrade a two data center disaster recovery deployment, follow the API Connect on VMware upgrade procedures along with the additional procedures that are described in this topic.

Key points for two data center disaster recovery upgrade on VMware:

- Both data centers must be using the same version of API Connect, including down to the specific fix pack and interim fix level. Therefore, both data centers must be upgraded in the same maintenance window.
- Do not reboot any of the management or portal virtual machines until the end of the upgrade, even if you're instructed to do so by the **`apicup subsys health-check`** command during the upgrade process.
- Upgrade the management subsystems in both data centers before you upgrade the portal subsystems.
- For both the management and portal subsystems, start by upgrading the warm-standby data center first.

Upgrade steps for 2DCDR:

1. Review the Planning your API Connect upgrade on VMware.
2. Complete the Pre-upgrade preparation and checks VMware steps.
3. Upgrade the warm-standby management subsystem
4. Upgrade the active management subsystem.
5. Upgrade the warm-standby portal subsystem.
6. Upgrade the active portal subsystem.
7. Upgrade analytics and gateway subsystems as described in Upgrade on VMware.

How to upgrade when one data center is down

If you cannot get your failed data center back online and want to upgrade, you can convert your active data center to a stand-alone and upgrade it:

1. Ensure that the network links to the failed data center are removed, so that if the failed data center recovers unexpectedly, it cannot interfere with your active data center.
2. Convert the active data center to a stand-alone data center: Removing a two data center deployment.
3. Upgrade your active data center with the standard upgrade steps: Upgrade on VMware.

To restore 2DCDR, replace the API Connect deployment in your failed data center with a new installation at the same fix pack level as your upgraded active data center. Follow the steps in Installing a two data center deployment to configure 2DCDR between the data centers.

Troubleshooting upgrades on VMware

Review the following troubleshooting guidance if you encounter a problem while upgrading API Connect on VMware.

Ubuntu preupgrade failures during OVA upgrade from 10.0.8.0 or 10.0.5.8 to 10.0.8.1

Symptom

For the Ubuntu upgrade, API Connect uses a proxy service that responds with the required HTTP responses or packages for the upgrade. If this service is not operational, the upgrade will not continue and API Connect displays the following error:

```
Err:1 http://archive.ubuntu.com/ubuntu focal InRelease
  Could not connect to localhost:8080 (127.0.0.1). - connect (111: Connection refused)
Err:2 http://archive.ubuntu.com/ubuntu focal-updates InRelease
  Unable to connect to localhost:8080:
```

```
Err:3 http://archive.ubuntu.com/ubuntu focal-backports InRelease
  Unable to connect to localhost:8080:
Err:4 http://security.ubuntu.com/ubuntu focal-security InRelease
  Could not connect to localhost:8080 (127.0.0.1). - connect (111: Connection refused)
```

Cause

The Ubuntu preupgrade fails to upgrade to 10.0.8.1 on Open Virtualization Archive (OVA) airgapped environments due to include failed attempts to connect to the internet during the `do-release-upgrade` process, indicating that the proxy service is not functioning correctly.

Resolution

To resolve the issue, complete the following steps:

1. Run the following commands:
   a. If you need to interrupt the `apt update` command, press `Ctrl+C` to break out of the operation

   b. `sudo -i`

   c. `cd /usr/local/lib/record`

   d. `./proxy &`

2. Create a file called fix.sh, and add the following content:

```
#!/bin/bash
PACKAGES=("libpq5" "shim-signed" "shim" "iotop" "sysstat" "dstat" "ioping" "atop" )
PREFERENCES_DIR="/etc/apt/preferences.d"
# Loop through the package names
for PACKAGE_NAME in "${PACKAGES[@]}"; do
 # Get the installed version of the package
 PACKAGE_VERSION=$(dpkg-query -W -f='${Version}' $PACKAGE_NAME 2>/dev/null)

 if [ -z "$PACKAGE_VERSION" ]; then
 echo "Package '$PACKAGE_NAME' is not installed. Skipping."
 continue
 fi
 PREFERENCES_FILE="${PREFERENCES_DIR}/${PACKAGE_NAME}-preferences"
 # Write the pinning configuration to the file
 echo "Creating pin for package '$PACKAGE_NAME' version '$PACKAGE_VERSION'"
 echo "Package: $PACKAGE_NAME" | sudo tee $PREFERENCES_FILE > /dev/null
 echo "Pin: version $PACKAGE_VERSION" | sudo tee -a $PREFERENCES_FILE > /dev/null
 echo "Pin-Priority: 1001" | sudo tee -a $PREFERENCES_FILE > /dev/null
 echo "Package '$PACKAGE_NAME' is now pinned to version $PACKAGE_VERSION."
done
```

3. Run the following script:

```
bash ./fix.sh
```

4. Repeat the steps i-v under Steps 2.c.
5. Run the following command:

```
sudo apic lock
```

6. Reboot the VM:

```
sudo reboot
```

7. Run the following commands:

   a. `sudo -i`

   b. `systemctl stop record-proxy`

   c. `cd /usr/local/lib/record`

   d. `/proxy &`

   e. `sudo do-release-upgrade`

8. Verify that the Ubuntu upgrade is complete:

```
sudo lsb_release -a
```

The output should be:

```
No LSB modules are available.
Distributor ID: Ubuntu
Description:    Ubuntu 22.04.4 LTS
Release:        22.04
Codename:       jammy
```

Subsystem status reports `PreUpgrade check failed`

If you run:

```
apicup subsys status <subsystem name>
```

or

`apicup subsys health-check <subsystem name>`

and you see the message:

`Preupgrade check failed, retrying. See status.PreUpgradeCheck for more details.`

then gather logs and open a support case.

Upgrade from V10.0.7 fails with an automatic rollback

If the upgrade fails and the subsystem is in the **SUBSYSTEM_ROLLBACK** state, do not proceed with the upgrade. Open a support case and work with IBM Support to resolve the underlying problem before you attempt the upgrade again.

1. Contact IBM Support to resolve the problem that caused the upgrade to fail.
2. When the problem is resolved, run the upgrade again with the following command:

   `apicup subsys install <subsys> --skip-health-check --rollback-mode-update`

Some containers in the `kube-system` namespace show a status of `ErrImageNeverPull`

When upgrading, some of the containers in the **kube-system** namespace might show a status of**ErrImageNeverPull**. This happens due to Docker not successfully loading all images from the upgrade .tgz file. To resolve this issue and enable the upgrade to proceed, complete the following steps:

1. Run the following command to determine which node is missing the control plane files:

   `kubectl -n kube-system get pods -owide`

   This command returns the names of the nodes containing pods with the **ErrImageNeverPull** status, which indicates missing control plane files.

2. On the node that is missing the control plane files, run the following command to determine which versions of the control plane are missing:

   `cat /var/lib/apiconnect/appliance-control-plane-current`

3. For each missing control plane, run the following command on the same node to add it, replacing *<version>* with the version of the control plane:

   `ctr -k8s.io images import /usr/local/lib/appliance-control-plane/<version>/kubernetes.tar --all-platforms`

   If you have a kubernetes.tgz file instead of a kubernetes.tar file, the run this first:

   `gunzip /usr/local/lib/appliance-control-plane/<version>/kubernetes.tgz`

Skipping health check when re-running upgrade

The **apicup subsys install** command automatically runs **apicup health-check** prior to attempting the upgrade. An error is displayed if a problem is found that will prevent successful upgrade

In some scenarios, if you encounter an upgrade failure, an attempt to rerun **apicup subsys install** is blocked by errors found by **apicup health-check**. Even when you have fixed the error (such as reconfiguration of an incorrect upgrade CR), the failed upgrade can continue to cause the health check to fail.

You can workaround the problem by adding the **--skip-health-check** flag to suppress the health check:

`apicup subsys install <subsystem_name> --skip-health-check`

In this case, use of **--skip-health-check** allows the upgrade to rerun successfully.

Unexpected behavior in Cloud Manager and API Manager UIs after upgrade

Stale browser cache issues can cause problems after an upgrade. To remedy this problem, clear your browser cache, and open a new browser window.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.

Maintaining API Connect

You can use utilities to complete maintenance tasks such as backup, restore, and certificate management in a VMware environment.

Note: When maintaining API Connect, do not use **kubectl exec** commands to access API Connect pods unless advised by IBM.
Do not make any changes on the deployed VMs unless documented here or otherwise advised by IBM. Attempting to manually update packages, adding new users, or installing new software will likely cause problems. Operating system updates are handled by API Connect fix packs.

- **Advanced installation on VMware**
  Optionally install additional software.
- **Advanced configuration on VMware**
  Perform configuration tasks on your API Connect deployment on VMware.
- **Advanced configuration for management subsystem**
  Specify advanced configuration for the management subsystem.
- **Configuring rate limits on the gateway nodes on VMware**
  Create an env.yaml file on each Gateway node to configure the default rate limit.

- **Backing up and restoring on VMware**
  Backup and restore API Connect on VMware.
- **Disabling and re-enabling the analytics subsystem on VMware**
  Disable the analytics subsystem by shutting down the VM that hosts it.
- **Maintaining a two data center deployment**
  How to maintain a two data center disaster recovery (DR) deployment on VMware, including information about normal operation, failure handling, and recovery.
- **Monitoring and health checks**
  Monitor your deployment and complete health checks on subsystems.
- **Logging**
  Configure logging for your deployment on VMware.
- **Troubleshooting**
  Troubleshoot your deployment on VMware.

Advanced installation on VMware

Optionally install additional software.

See:

- **Installing the IBM License Metric Tool on VMware**
  The IBM® License Metric Tool (ILMT) helps you determine whether your IBM API Connect deployment is compliant with licensing requirements.
- **Installing the toolkit**
- **Installing the Automated API behavior testing application**
  Install the Automated API behavior testing application in your IBM API Connect deployment on VMware.

Installing the IBM License Metric Tool on VMware

The IBM® License Metric Tool (ILMT) helps you determine whether your IBM API Connect deployment is compliant with licensing requirements.

About this task

ILMT provides useful features for managing virtualized environments and measuring license utilization. ILMT discovers the software that is installed in your infrastructure, helps you to analyze the consumption data, and allows you to generate audit reports. Each report provides you with different information about your infrastructure; for example the computer groups, software installations, and the content of your software catalog.

By default, every ILMT audit report presents data from the previous 90 days. You can customize the type and amount of information displayed in a report by using filters, and save your personal settings for future use. You can also export the reports to .csv or .pdf format, and schedule report emails so that specified recipients are notified when important events occur.

To deploy the ILMT with API Connect, complete the following steps for the Management, Developer Portal, and Analytics OVAs. The instructions refer to topics in the ILMT documentation:

Procedure

1. Add a disconnected data source to your ILMT deployment as explained in Adding a data source.
2. Download the scanner installer as explained in Downloading the disconnected scanner package (disconnected scenario).
3. Install the scanner and run scans as explained in Installing the disconnected scanner and gathering scan results (disconnected scenario).
4. Set up daily transfer of scan results to ILMT as explained in Setting up daily transfer of scan results to the License Metric Tool server (disconnected scenario).

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just to need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + Designer: provides a command line environment for working with IBM API Connect, including API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
   - To download the toolkit from IBM Fix Central, complete the following steps:
     - Open the IBM Fix Central site in your browser.
     - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
     - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
     - In the Text field, enter `toolkit`, then click Continue.
     - Select the toolkit file that you want to download.
     - Click Continue, then follow the instructions to complete the download operation.
   - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
     - Open the Cloud Manager or API Manager user interface.
     - On the welcome page, click the Download Clients tile. The two toolkit options are listed under the Toolkit tab.
     - Click your platform alongside either the CLI option or the CLI + Designer option as required, then save the associated compressed file to your local file system.
     - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the designer_credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 5.
     - To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 4.
2. Extract the contents of the toolkit compressed file to a folder of your choice.
   The contents of the file depend on the your chosen toolkit option and platform, as follows:
   - The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.
   - The apic or apic.exe file is the CLI for IBM API Connect.
     Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + Designer option.
   - The api_designer-*platform* file is the API Designer user interface application for the specified platform.
3. Run the CLI.
   - For the macOS or Linux® platforms, complete the following steps:
     - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Make the CLI file an executable file by entering the following command:

       ```
       chmod +x download_name
       ```

       Where *download_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.
     - If you are using macOS, remove the quarantine attribute by running the following command:

       ```
       sudo xattr -dr com.apple.quarantine apic-slim
       ```

     - Run CLI commands as follows:

       ```
       ./apic command_name_and_parameters
       ```

       or

       ```
       ./apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see the toolkit CLI reference documentation.
   - For the Windows platform, complete the following steps:
     - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Run CLI commands as follows:

       ```
       apic command_name_and_parameters
       ```

       or

       ```
       apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see the toolkit CLI reference documentation.

   Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.
4. Install the toolkit credentials.
   If you do not install the toolkit credentials that are provided for download, as detailed previously in the toolkit credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

   ```
   apic client-creds:set toolkit_credentials_file_path/credentials.json
   ```

   where *credentials_file_path* is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.
   Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
   To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

   ```
   apic client-creds:clear
   ```

   For increased security, an administrator can remove the default credentials from the management server by completing the following steps:
   a. Log in to the management server as an administrator; see Logging in to a management server.
   b. Delete the default credentials by running the following commands:

   ```
   apic registrations:delete toolkit --server mgmt_endpoint_url
   apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
   ```

5. Install the API Designer credentials.

If you do not install the API Designer credentials that are provided for download, as detailed previously in the API Designer credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the **APIC_DESIGNER_CREDENTIALS** environment variable to the credentials download location, using the mechanism appropriate for your operating system.

After you have set the **APIC_DESIGNER_CREDENTIALS** environment variable, your API Designer uses the new credentials to authenticate with the management server.

- Windows:
  If you are using Windows, create an environment variable using one of the following methods:
  - Create a permanent environment variable so that you can start API Designer from any location on your computer:
    - Open the Environment Variables page: Click Start > Settings > System and in the "Related Settings" section of the page, click Advanced System Settings.
    - On the Advanced tab of the System Properties dialog box, click Environment Variables.
    - In the "User variables" section, click New and create an environment variables with the following settings:
      - Variable: **APIC_DESIGNER_CREDENTIALS**
      - Value: *<designer_credentials_file_path>*\designer_credentials.json where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.
    - Click OK to save the new environment variable, and then exit the dialog box.
  - If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
    - Open the Windows command prompt.
    - Run the following command to set the temporary environment variable:

      ```
      set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
      ```

      where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.

      Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.
    - Now run the following command to start API Designer:

      ```
      C:\"Program Files\API Designer\API Designer.exe"
      ```

      By default, API Designer is installed in the C:\"Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.
- Mac:
  If you are using macOS, create an environment variable using one of the following methods:
  - Run the following command to set the global environment variable:

    ```
    launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
    ```

    where ***<designer_credentials_file_path>*** is the location where you stored the API Designer credentials JSON file.
  - Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

    ```
    APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
    <designer_application_file_path>/'API Designer.app'
    ```

    where:
    - ***<designer_credentials_file_path>*** is the location to which you downloaded the API Designer credentials JSON file.
    - ***<designer_application_file_path>*** is the location to which you downloaded and uncompressed the API Designer application.

6. Start the API Designer application from the location to where you stored the extracted file.
   Note:
   - To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
     - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
     - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
   - To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see Developing your APIs and applications.

For information on using the toolkit CLI, see Using the developer toolkit command-line tool.

Installing the Automated API behavior testing application

Install the Automated API behavior testing application in your IBM® API Connect deployment on VMware.

About this task

Use the following steps to install the Automated API behavior testing application as part of your initial deployment, or to add it in later.
Note: It is not possible to use the Automated API behavior testing application with a two data center disaster recovery configuration (Two data center warm-standby deployment strategy on VMware).

Enabling `Autotest` (optional)

You may choose to enable `Autotest`, which is an optional feature that allows for automated testing of API behavior. if you decide to enable `Autotest`, monitor the following pods: `atm-api`, `atm-ui`, and `autotest-service` pods, to ensure that they are running correctly and that the `Autotest` is initiating successfully.

Procedure

1. To install or update your deployment with the Automated API behavior testing application without `Autotest`, run the following `apicup` commands:

   ```
   apicup subsys set mgmt test-and-monitor-enabled true
   apicup subsys install mgmt
   ```

   where, *`mgmt`* is the name of your Management server (which you are either installing or updating).

2. To install or update your deployment with the Automated API behavior testing application, with `Autotest` enabled, run the following `apicup` commands :

   ```
   apicup subsys set mgmt test-and-monitor-enabled true
   apicup subsys set mgmt auto-test-enabled true
   apicup subsys install mgmt
   ```

   where, *`mgmt`* is the name of your Management server (which you are either installing or updating).

3. Verify that the pods are running by executing *`watch 'kubectl get pods -n <management_namespace>'`* and monitoring the new *`atm-api`* and *`atm-ui`* pods periodically until the READY column displays 1/1 and the STATUS column is updated to Running.
4. Verify that the application is deployed properly by completing the following steps:
   a. Log in to API Manager.
   b. On the home page, click the Test APIs tile.
   c. Verify that the Automated API behavior testing opens.

Advanced configuration on VMware

Perform configuration tasks on your API Connect deployment on VMware.

See:

- **Adding a static route on a virtual machine**
  You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.
- **Adding disk space to a VMware appliance**
  Increase disk space on the VMware appliance.
- **Appliance boot mode configuration**
  Configure the boot mode for the appliance VMs.
- **Running commands at boot with iso-ignored boot mode**
  When `iso-ignored` boot mode is configured, complete the following steps on each appliance that should run commands at boot.
- **Changing deployment profiles on VMware**
  You can change an API Connect installation to use a different deployment profile.
- **Changing the DNS server configuration**
  Update the DNS addresses on your API Connect VMs.
- **Configuring API Connect subsystems in a cluster**
  This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.
- **Overriding NTP server configuration**
  Override the hostname set for the NTP server on your VMs.
- **Configuring SSHD to limit access to your deployment**
  How to configure SSHD in order to limit host access to your VMware deployment, or to change the SSHD cipher level.
- **Enabling Developer Portal feature flags on VMware**
  Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.
- **Specifying a range of allowable client IP addresses for the portal**
  Specify the range of client IP addresses to be allowed in a deployment of the portal
- **Managing an appliance data disk**
  You can use `apic` commands to manage appliance data disks in your VMware deployment.
- **Replica override for microservices on VMware**
  Modify the replica count for microservices by using template overrides for Custom Resources.
- **Testing a new configuration against a current cluster**
  You can use the `apicup` utility to test the validity of a new configuration before you install it.
- **TLS certificate concepts and operations**
  Information about internal API Connect certificates, renewing expired certificates, exporting certificates, and other certificate maintenance operations.
- **Use JWT security instead of mTLS between subsystems**
  If your network requires TLS termination on load-balancers located between your API Connect subsystems, then disable mTLS and enable JWT to provide application layer security.
- **Credentials and encryption secrets reference**
  API Connect user credentials and database encryption secrets that are managed with the **apicup certs** command.

Adding a static route on a virtual machine

You can add a static route to the routing table when deploying API Connect on a VMware virtual machine.

About this task

Add commands to your additional **cloud-init** file. You can do this for the Management, Analytics, and Portal subsystems.

Procedure

1. Specify an additional cloud-init file:

   ```
   apicup subsys set <subsys> additional-cloud-init-file <path-to-cloud-init-file>
   ```

2. Add lines to your cloud-init file.
   Syntax:

   ```
   bootcmd:
    - ip route add <destination>/<mask> via <gateway> dev eth<n>
   ```

   Example:

   ```
   bootcmd:
    - ip route add 172.27.218.0/24 via 172.27.218.1 dev eth1
    - ip route add 172.26.203.0/24 via 172.27.218.1 dev eth1
   ```

3. Regenerate the ISO file.

   ```
   apicup subsys install <subsys> --out <plan-directory>
   ```

4. Restart the ISO, and ensure that the node(s) have this updated ISO attached at startup.

Adding disk space to a VMware appliance

Increase disk space on the VMware appliance.

About this task

For multi-node deployment of the appliance, only one VM at a time should have its disk space augmented. The subsystem should be in good health before proceeding to the next node. Health of the subsystem can be checked with **apicup subsys health-check <subsystem-name>**.
Attention:

- Before you begin the steps to add disk space to the VMware appliance, take a snapshot of the VMware.
- Do not remove the disk abruptly during the process as currently, the steps to remove the disks are not supported.

Restriction:
The increased disk capacity of a VMware appliance won't be reflected in the storage size of the PVCs that are hosted on the appliance, as those PVCs are immutable. This restriction doesn't impact the Portal and Analytics subsystems, as the PVC storage size isn't used to enforce any disk usage limit, so the subsystems can use all of the additional disk space. However, for the Management subsystem the PVC storage size is used in the database storage utilization computation, and that might trigger disk usage warnings.

The most common reason for the Management subsystem database to run out of disk space, is due to Write Ahead Log (WAL) file accumulation in relation to an incorrectly configured backup, or an unavailable backup server. If this type of condition arises, adding disk space might help with the health of the appliance control plane, but it won't increase the disk space that's available to the database, so you must resolve the WAL file accumulation condition. If the disk space that's available to the Management database must be increased, you should carry out a disaster recovery operation of the Management subsystem, using a larger data disk size for the new installation, so that adding disk space after the install won't be needed.

Procedure

1. Shutdown the virtual machine, either by issuing a shutdown command as root from the VM, or by using the VMware console or command line interface.
   For example, use the VMware console user interface and click the red rectangle.

2. Use either the VMware console or command line interface to add a new device to the VM, of type Hard Disk and of the desired size to be added to the appliance.
   For example, on the VMware console:
   a. Click Edit settings.
   b. Click Add new device. From the drop-down menu, select Hard Disk.
   c. Enter size in GB and click OK.
3. Use either the VMware console or the command line interface to power on the VM.
   As the VM starts it should detect the newly added disk and use it to augment the available capacity for the /data/secure mount point.
4. Optionally you may verify that a new disk **sdc** was added (or **sdd** if you already added one disk, and so on). Log in to the server and observe the new disk. For example:

   ```
   root@apimdev1139:~# lsblk
   NAME                MAJ:MIN RM  SIZE RO TYPE  MOUNTPOINT
   sda                   8:0    0  100G  0 disk
   ├─sda1                8:1    0 99.9G  0 part  /
   ├─sda14               8:14   0    4M  0 part
   └─sda15               8:15   0  106M  0 part  /boot/efi
   sdb                   8:16   0  250G  0 disk
   └─apiconnect-data   252:0    0  260G  0 lvm
     └─apicSecureDisk  252:1    0  260G  0 crypt /data/secure
   sdc                   8:32   0   10G  0 disk
   └─apiconnect-data   252:0    0  260G  0 lvm
     └─apicSecureDisk  252:1    0  260G  0 crypt /data/secure
   sr0                  11:0    1   44K  0 rom
   ```

Appliance boot mode configuration

Configure the boot mode for the appliance VMs.

By default every appliance node requires the presence of an ISO file attached at boot.

You can configure individual VMs so that they can be booted and rebooted without an ISO being attached. Each appliance VM (node) is configured individually.

You can:

- Check the current boot mode of an appliance
- Configure an appliance for iso-ignored boot mode
- Configure an appliance for iso-required boot mode
- Revert back to iso-required boot mode by booting the appliance in rescue mode

Check the current boot mode of an appliance

The default boot mode for all appliances is **iso-required**. To check the current boot mode:

1. Connect to the target appliance via SSH then switch to the root user:

   ```
   ssh apicadm@{ova appliance hostname}
   sudo -i
   ```

2. Use **apic boot-mode** to check the current boot mode of the appliance. For example:

   ```
   root@ip-192-168-122-241:~# apic boot-mode
   INFO[0000] Log level: info
   INFO[0000] current boot mode is: iso-required
   ```

Configure an appliance for iso-ignored boot mode

An appliance can be configured to use the **iso-ignored** boot mode instead of the default **iso-required**. Prerequisite: The appliance must have first booted with its configuration ISO attached and in **iso-required** boot mode (default) before the boot mode can be changed to **iso-ignored**.

You can configure an appliance to use he **iso-ignored** boot mode instead of the default **iso-required**.

Prerequisite: The appliance must have first booted with its configuration ISO attached and in **iso-required** boot mode (default), before you can change the boot mode to **iso-ignored**.

Note: If you added a static route to the routing table, as documented in Adding a static route on a virtual machine, and if you are relying on a **bootcmd** from the ISO, then using the **iso-ignored** boot mode causes the **bootcmd** section being ignored or ineffective.

1. Connect to the target appliance via SSH then switch to the root user:

   ```
   ssh apicadm@{ova appliance hostname}
   sudo -i
   ```

2. Edit the file **/etc/default/grub.d/50-cloudimg-settings.cfg** to ensure that the **GRUB_TIMEOUT** and **GRUB_RECORDFAIL_TIMEOUT** are set to the value **5**. Then run the command **update-grub**. For example:

   ```
   root@ip-192-168-122-241:~# update-grub
   Sourcing file `/etc/default/grub'
   Sourcing file `/etc/default/grub.d/50-cloudimg-settings.cfg'
   Sourcing file `/etc/default/grub.d/init-select.cfg'
   Generating grub configuration file ...
   Found linux image: /boot/vmlinuz-5.4.0-84-generic
   Found initrd image: /boot/initrd.img-5.4.0-84-generic
   done
   ```

3. Set the appliance boot mode to **iso-ignored** with the command **apic boot-mode iso-ignored**. For example:

   ```
   root@ip-192-168-122-241:~# apic boot-mode iso-ignored
   INFO[0000] Log level: info
   INFO[0000] current boot mode is: iso-ignored
   ```

4. Shutdown the VM, and remove the CD/DVD device from the VM configuration through VSphere.
   For any subsequent boot of the appliance while it remains in **iso-ignored** boot mode, any ISO file attached will be ignored, and the boot will proceed as normal, whether an ISO file is attached or not.

   Warning: If the appliance was booted in **iso-ignored** boot mode, it is possible to change its boot mode to **iso-required**. However, as stated in the prerequisites, it is not possible to immediately switch back to **iso-ignored**, and the next boot of the appliance must happen with the configuration ISO attached and boot mode **iso-required**.

Configure an appliance for iso-required boot mode

The mode **iso-required** is the default boot mode for all appliances. If the appliance boot mode was changed to **iso-ignored** you can revert back to **iso-required** boot mode.

Warning:
If the appliance was booted in **iso-ignored** boot mode, it is possible to change its boot mode to **iso-required**. However, you cannot immediately switch back to **iso-ignored**, and the next boot of the appliance must happen with the configuration ISO attached and boot mode **iso-required**. After the appliance is booted with ISO attached in **iso-required** boot mode, the boot mode can then be switched to **iso-ignored** if needed.

1. Connect to the target appliance via SSH then switch to the root user:

```
ssh apicadm@{ova appliance hostname}
sudo -i
```

2. Set the appliance boot mode to **iso-required** with the command **apic boot-mode iso-required**. For example:

```
root@ip-192-168-122-241:~# apic boot-mode iso-required
INFO[0000] Log level: info
INFO[0000] current boot mode is: iso-required
```

Important: For any subsequent boot of the appliance while it remains in **iso-required** boot mode, the configuration ISO file must be connected at boot and for every boot.

Revert back to iso-required boot mode by booting the appliance in rescue mode

When an appliance is configured with the **iso-ignored** boot mode, the boot sequence ignores any attached ISO. This means that it is not possible to influence the appliance configuration during its boot. In case the appliance is not booting properly and the boot mode needs to be reverted back to **iso-required**, proceed as follows:

1. Access to the VMware console for the Appliance, and after causing it to reboot, bring up a console to the appliance. You can give focus to the window by clicking the mouse into it. Press the **Esc** key to access the Linux grub boot menu. For example:

```
GNU GRUB version 2.04

*Ubuntu
Advanced options for Ubuntu
```

2. Press **e** and navigate using arrow keys to the line starting with **linux** to append **systemd.unit=rescue.target**

```
GNU GRUB version 2.04
.
.
.
insmod part_gpt
insmod ext2
if [ x$feature_platform_search_hint = xy ];  then
   search --no-floppy --fs-uuid --set=root e46da1b8-55ao-4df9-842e-\
     8d80c3a22ffc
else
   search --no-floppy --fs-uuid --set=root e46da1b8-55ao-4df9-842e-8\
     d80c3a22ffc
fi
linux      /boot/vmlinuz-5.4.0-84-generic root=LABEL=cloudimg-roo\
   tfs ro console=tty1 console=ttyS0 net.ifnames=0 bioosdevname=0 systemd.unit\
   =rescue.target
initrd     /boot/initrd.img-5.4.0-84-generic
```

3. Press **Ctrl+x** to boot.
4. Press **Enter** to enter maintenance mode. Run the commands:

```
rm -f /etc/cloud/cloud-init.disabled
```

and

```
echo -n "iso-required" > /usr/local/lib/appliance-config/boot-mode
```

```

(or press Ctrl-D to continue):
root#ip-192-168-122-241:~# rm -f /etc/cloud/cloud-init.disabled
root#ip-192-168-122-241:~# echo -n "iso-required" > /usr/local/lib/appliance-config/boot-mode
root#ip-192-168-122-241:~#
```

5. Reboot the appliance with correct configuration ISO attached.

Running commands at boot with iso-ignored boot mode

When **iso-ignored** boot mode is configured, complete the following steps on each appliance that should run commands at boot.

About this task

If you configured the appliance to boot in **iso-ignored** mode as documented in Appliance boot mode configuration, the **bootcmd** lines will be ignored. For each appliance node that should run commands at boot, complete the following steps.

Procedure

1. SSH into the appliance as root.
2. Create the /usr/local/bin/appliance-boot-commands.sh script to be executed at boot; for example:

```
cat << EOF > /usr/local/bin/appliance-boot-commands.sh
#!/bin/bash

ip route add 172.27.218.0/24 via 192.168.122.1 dev eth0
ip route add 172.26.203.0/24 via 192.168.122.1 dev eth0
EOF
```

   This step takes the same example, and essentially achieves the same result, as the procedure in Adding a static route on a virtual machine.

3. Make the script executable by running the following command:

```
chmod +x /usr/local/bin/appliance-boot-commands.sh
```

4. Create the following systemd service file /lib/systemd/system/appliance-boot-commands.service:

```
cat << EOF > /lib/systemd/system/appliance-boot-commands.service
[Unit]
After=network-online.target

[Service]
Type=oneshot
ExecStart=/usr/local/bin/appliance-boot-commands.sh
RemainAfterExit=false
StandardOutput=journal

[Install]
WantedBy=multi-user.target
EOF
```

5. Enable the systemd service by running the following command:

```
systemctl enable appliance-boot-commands
```

   Upon subsequent boots, the **/usr/local/bin/appliance-boot-command.sh** script will be executed.

Changing deployment profiles on VMware

You can change an API Connect installation to use a different deployment profile.

For information on the available deployment profiles, see Planning your deployment topology and profiles. The steps for changing deployment profile after installation depend on whether you want to change to a profile that has a different number of VMs and whether additional CPU and memory resources are required for the profile you move to.
Note: The procedures to change deployment profile that are described in this topic do not permit the endpoints to be changed. The API Connect endpoints are listed here: Deployment overview for endpoints. If you want to change a one replica deployment to a three replica deployment, and you used your VM hostnames in your endpoints, then you must configure load-balancers and logical DNS records so that your original VM hostnames route to your new VMs. Alternatively, you can change endpoints by following the form factor migration procedure: Migrating from v10 to v10 on a different form factor.

Moving to a profile that has the same number of VMs

If you are moving to a profile that requires greater CPU and memory resources, follow these steps:

1. Ensure that you have complete backups of your subsystems and project directory Backing up and restoring on VMware.
2. Shutdown your API Connect VMs.
3. Update the CPU and memory resources for your API Connect VMs in your VMware console, as required for your new profile.
4. Restart your VMs.
5. In your project directory, update your deployment profile:

```
apicup subsys set <subsystem_name> deployment-profile=<new profile>
```

6. Apply the new profile:

```
apicup subsys install <subsystem_name>
```

If you are moving to a profile that requires lower CPU and memory resources, follow these steps:

1. Ensure that you have complete backups of your subsystems and project directory Backing up and restoring on VMware.
2. In your project directory, update your deployment profile:

```
apicup subsys set <subsystem_name> deployment-profile=<new profile>
```

3. Apply the new profile:

```
apicup subsys install <subsystem_name>
```

4. Shutdown your API Connect VMs.
5. Update the CPU and memory resources for your API Connect VMs in your VMware console, as required for your new profile.
6. Restart your VMs.

If for any reason you are not able to change the CPU or memory on your VMs, redeploy them following the disaster recovery process: Disaster recovery.

Moving from a one replica to a three replica deployment profile

1. Ensure that you have complete backups of your subsystems and project directory Backing up and restoring on VMware.
   Note: You do not need to take VMware snapshots, since your existing VMs are deleted and replaced when you change deployment profile.
2. In your project directory, update your deployment profile:

   ```
   apicup subsys set <subsystem_name> deployment-profile=<three replica profile>
   ```

3. Define the hostname and network interfaces for the two new VMs in each of your subsystems. Use the `apicup hosts create` and `apicup iface create` commands. For more information, see the hosts and interface create steps in the installation instructions for each subsystem:
   - Preparing the management subsystem for deployment.
   - Preparing the analytics subsystem for deployment.
   - Preparing the portal subsystem for deployment.
4. Shutdown your existing API Connect VMs.
   Note: To minimize downtime, you can delay shutting down your existing deployment until you are about to deploy their replacement VMs in the next step.
5. Follow the disaster recovery steps for each subsystem: Disaster recovery, but note that you must create new ISO files. Do not attempt to reuse the previous ISO file for one of the VMs in your new three replica deployment.

Moving from a three replica to a one replica deployment profile

1. Ensure that you have complete backups of your subsystems and project directory Backing up and restoring on VMware.
   Note: You do not need to take VMware snapshots, since your existing VMs are deleted and replaced when you change deployment profile.
2. In your project directory, update your deployment profile:

   ```
   apicup subsys set <subsystem_name> deployment-profile=<one replica profile>
   ```

3. Delete two of your three VMs from your configuration with the `apicup hosts delete` command.
4. Shutdown your existing API Connect VMs.
   Note: To minimize downtime, you can delay shutting down your existing deployment until you are about to deploy their replacement VMs in the next step.
5. Follow the disaster recovery steps for each subsystem: Disaster recovery, but note that you must create new ISO files. Do not attempt to reuse any previous ISO files for your new one replica deployment.

Changing the DNS server configuration

Update the DNS addresses on your API Connect VMs.

About this task

This task covers how to update the DNS name servers list on your API Connect VMs. Other network properties such as the VM IP address and hostname cannot be changed after deployment.

Procedure

1. Log in to each API Connect VM.

   ```
   ssh apicadm@<vm hostname>
   ```

2. Edit the /etc/netplan/50-cloud-init.yaml file and update the list of name server addresses.

   ```
   sudo vi /etc/netplan/50-cloud-init.yaml
   ```

   The following example shows what the list of name server addresses looks like in the file:

   ```
   network:
       ethernets:
           eth0:
               addresses:
               - 192.168.122.242/24
               nameservers:
                   addresses:
                   - 1.1.1.1
                   - 1.0.0.1
                   - 8.8.8.8
                   search:
                   - nip.io
               routes:
               -   metric: 10
                   to: 0.0.0.0/0
                   via: 192.168.122.1
       version: 2
   ```

   Attention: Do not change anything else in this file. Change only the `namerservers.addresses` contents.
3. Run the following command to apply the changes:

```
sudo netplan apply
```

4. Run the following command to verify the changes:

   ```
   cat /run/systemd/resolve/resolv.conf
   ```

5. Repeat steps 1 to 4 on all your API Connect VMs.
6. From your project directory, specify the DNS servers with the **apicup** command:

   ```
   apicup subsys set <subsystem name> dns-servers=ip_address_of_dns_server[,ip_address_of_another_dns_server_if_necessary]
   ```

   Use a comma to separate multiple server addresses.

7. Create new ISO files for your API Connect deployment

   ```
   apicup subsys install <subsystem name> --out <subsystem name>plan-out
   ```

   Important: Setting `dns-servers` with **apicup** does not update the DNS servers on the deployed VMs, but it does ensure that the new ISO files you create contain these updated settings. In a disaster recovery scenario where you must redeploy your VMs, if you deploy with your original ISO files (that contain your old DNS config), then you must repeat this task after the VMs are deployed.

Configuring API Connect subsystems in a cluster

This topic describes how to configure a cluster of API Connect subsystems (management server, analytics, and Developer Portal) with three VMs for each subsystem, for use with a load balancer, to support a high availability (HA) environment.

Before you begin

To create a cluster of hosts for each API Connect subsystem, use `apicup` to create a subsystem with all the required parameters, and to add as many hosts as needed to the configuration file. The configuration file is a .yml file in the project directory.

For each host of a subsystem added in the .yml file, a separate ISO file is created for the cluster member VM. Note that the ISO files for each VM must stay attached during the whole lifetime of the VM.

In an API Connect cluster in a VMware environment, the first three nodes are master nodes. Additional nodes are worker nodes.

Note: To add a new host to an existing cluster, you can create the host, regenerate the ISO and attach it to the new virtual machine, and it will automatically join the cluster.
To use these instructions, you should first review:

- VMware deployment overview and requirements
- Load balancer configuration in a VMware deployment
- Deployment overview for endpoints
- Firewall requirements on VMware
- Firewall enabled ports for clustered OVA deployments
- Important: For best performance, it is recommended that the network latency between the nodes be as low as possible. Do not configure nodes from the same subsystem cluster across multiple data centers with a high latency network. A high latency network is one that experiences more than 6 ms latency between nodes.

About this task

This page presents a concise step-by-step flow, with sample commands, for the configuration of each subsystem. As you step through the flow, you might want to refer back to the detailed configuration steps for each subsystem. The detailed instructions provide additional considerations for each step, and include optional configuration tasks for backups, logging, message queues (analytics), and password hashing. Each of the subsystem pages describe how to use the VMware console to deploy the ISOs that you create here.

Detailed configuration steps:

- Installing the management subsystem on VMware
- Installing the analytics subsystem on VMware
- Installing the developer portal subsystem on VMware

The example commands uses the following values for DNS server, internet gateway, host names and IP addresses:

Component	Host names and IP addresses
DNS Name Server	`IP: 192.168.1.1`
Internet gateway	`IP: 192.168.1.2`
Manager on VM1	`Hostname: manager1.sample.example.com` `IP: 192.168.1.101`
Manager on VM2	`Hostname: manager2.sample.example.com` `IP: 192.168.1.102`
Manager on VM3	`Hostname: manager3.sample.example.com` `IP: 192.168.1.103`
Analytics on VM4	`Hostname: analytics1.sample.example.com` `IP: 192.168.1.104`
Analytics on VM5	`Hostname: analytics2.sample.example.com` `IP: 192.168.1.105`
Analytics on VM6	`Hostname: analytics3.sample.example.com` `IP: 192.168.1.106`
Developer Portal on VM7	`Hostname: portal1.sample.example.com` `IP: 192.168.1.107`

Component	Host names and IP addresses
Developer Portal on VM8	`Hostname: portal2.sample.example.com` `IP: 192.168.1.108`
Developer Portal on VM9	`Hostname: portal3.sample.example.com` `IP: 192.168.1.109`

Procedure

1. Create the Management subsystems
   a. Create the Management subsystem.

      ```
      apicup subsys create mgmt management
      ```

   b. Set deployment-profile to **n3xc4.m16**.

      ```
      apicup subsys set mgmt deployment-profile=n3xc4.m16
      ```

      If you omit this step, the deployment-profile defaults to **n1xc4.16**, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

   c. Specify the license version you purchased.
      apicup subsys set *mgmt*
      license-use=<*license_type*>

      The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

   d. Set management endpoints
      Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
Management REST API URL	`apicup subsys set mgmt platform-api platform-api.sample.example.com`
Consumer (Portal) REST API URL	`apicup subsys set mgmt consumer-api consumer-api.sample.example.com`
Cloud Manager UI	`apicup subsys set mgmt cloud-admin-ui cloud-admin-ui.sample.example.com`
API Manager UI	`apicup subsys set mgmt api-manager-ui api-manager-ui.sample.example.com`

   e. Set the search domain for the VM.

      ```
      apicup subsys set mgmt search-domain sample.example.com
      ```

   f. Set the DNS Name Server for the VM to look up endpoints.

      ```
      apicup subsys set mgmt dns-servers 192.168.1.1
      ```

   g. Set a Public Keyfile.
      This is the public key of the user account that you want to use to **ssh** from, to the appliance.

      ```
      apicup subsys set mgmt ssh-keyfiles "id_rsa.pub"
      ```

   h. Create the hosts for the subsystem.
      You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the previous example with a strong password that meets your security requirements.

      ```
      apicup hosts create mgmt manager1.sample.example.com password123
      apicup hosts create mgmt manager2.sample.example.com password123
      apicup hosts create mgmt manager3.sample.example.com password123
      ```

   i. Set the network interface. Note that the last parameter is the Internet Gateway.

      ```
      apicup iface create mgmt manager1.sample.example.com eth0 192.168.1.101/255.255.255.0 192.168.1.2
      apicup iface create mgmt manager2.sample.example.com eth0 192.168.1.102/255.255.255.0 192.168.1.2
      apicup iface create mgmt manager3.sample.example.com eth0 192.168.1.103/255.255.255.0 192.168.1.2
      ```

   j. Set the network traffic interfaces.

      ```
      apicup subsys set mgmt traffic-iface eth0
      apicup subsys set mgmt public-iface eth0
      ```

   k. Verify the host configuration.

      ```
      apicup hosts list mgmt
      ```

      Note: This command might return the following messages, which you can ignore:

      ```
      * host is missing traffic interface
      * host is missing public interface
      ```

   l. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

      ```
      apicup subsys set mgmt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
      ```

      Important: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.
   m. Validate the installation.

      ```
      apicup subsys get mgmt --validate
      ```

   n. Create an ISO file in a plan folder. For example, **mgmtplan-out**.

      ```
      apicup subsys install mgmt --out mgmtplan-out
      ```

If you have multiple nodes listed for the hosts, when you run the **--out** command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

o. To deploy the management ISOs on VMware, see Deploying the management subsystem OVA.

2. Create the analytics subsystems
   a. Create the subsystem:

   ```
   apicup subsys create analyt analytics
   ```

   b. Set deployment-profile to **n3xc4.m16**.

   ```
   apicup subsys set analyt deployment-profile=n3xc4.m16
   ```

   If you omit this step, the deployment-profile defaults to **n1xc2.16**, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

   c. Specify the license version you purchased.

   ```
   apicup subsys set analyt
   license-use=<license_type>
   ```

   The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

   d. Set analytics ingestion endpoint
   Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following value points to a sample load balancer URL.

Component	Command
analytics-ingestion	`apicup subsys set analyt analytics-ingestion=analytics-ingestion.sample.example.com`

   e. Set the search domain for the VM.

   ```
   apicup subsys set analyt search-domain sample.example.com
   ```

   f. Set the DNS Name server for the VM to look up endpoints.

   ```
   apicup subsys set analyt dns-servers 192.168.1.1
   ```

   g. Set a Public Keyfile.
   This is the public key of the user account that you want to use to **ssh** from, to the appliance

   ```
   apicup subsys set analyt ssh-keyfiles "id_rsa.pub"
   ```

   h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

   ```
   apicup subsys set analyt default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
   ```

   Important: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.

   i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses. Replace the example password in the following password with a strong password that meets your security requirements.

   ```
   apicup hosts create analyt analytics1.sample.example.com password123
   apicup hosts create analyt analytics2.sample.example.com password123
   apicup hosts create analyt analytics3.sample.example.com password123
   ```

   j. Set the network interface.
   Note that the last parameter is the Internet Gateway.

   ```
   apicup iface create analyt analytics1.sample.example.com eth0 192.168.1.104/255.255.255.0 192.168.1.2
   apicup iface create analyt analytics2.sample.example.com eth0 192.168.1.105/255.255.255.0 192.168.1.2
   apicup iface create analyt analytics3.sample.example.com eth0 192.168.1.106/255.255.255.0 192.168.1.2
   ```

   k. Check the host configuration for problems.

   ```
   apicup hosts list analyt
   ```

   l. Validate the installation.

   ```
   apicup subsys get analyt --validate
   ```

   m. Create an ISO file in a plan folder. For example, **analytplan-out**.

   ```
   apicup subsys install analyt --out analytplan-out
   ```

   If you have multiple nodes listed for the hosts, when you run the **--out** command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

   n. To deploy the ISOs, see Deploying the analytics subsystem OVA.

3. Create the portal subsystems
   a. Create the portal.

   ```
   apicup subsys create port portal
   ```

   b. For three replica environments, set deployment-profile to **n3xc4.m8**.

   ```
   apicup subsys set port deployment-profile=n3xc4.m8
   ```

   If you omit this step, the deployment-profile defaults to **n1xc4.m8**, which is for non-HA environments, and will not support three instances of the subsystem in one cluster.

   c. Specify the license version you purchased.

```
apicup subsys set port
license-use=<license_type>
```

The *license_type* must be either **production** or **nonproduction**. If not specified, the default value is **nonproduction**.

d. Set the portal endpoints.
Endpoints can point to VM host names, but in cluster deployments typically point to a load balancer. The load balancer distributes requests over the 3 VMs. The following values point to a sample load balancer URL.

Component	Command
portal-admin	`apicup subsys set port portal-admin=portal-admin.sample.example.com`
portal-www	`apicup subsys set port portal-www=portal-www.sample.example.com`

e. Set the search domain for the VM.

```
apicup subsys set port search-domain sample.example.com
```

f. Set the DNS Name server for the VM to look up endpoints.

```
apicup subsys set port dns-servers 192.168.1.1
```

g. Set a Public Keyfile.
This is the public key of the user account that you want to use to **ssh** from, to the appliance

```
apicup subsys set port ssh-keyfiles "id_rsa.pub"
```

h. Set a hashed password to access the appliance VM through the VMware Remote Console. Use an operating system utility to create a hashed password, and then use **apicup** to set the hashed password for your subsystem:

```
apicup subsys set port default-password='$1$aTD7uXAO$kNoMAefjGKBwMFiu.8ctr0'
```

Important: Review the requirements for creating and using a hashed password. See Setting and using a hashed default password.

i. Create the hosts for the subsystem. You must specify a password to use to encrypt the disks that the appliance uses.

```
apicup hosts create port portal1.sample.example.com password123
apicup hosts create port portal2.sample.example.com password123
apicup hosts create port portal3.sample.example.com password123
```

Replace the example password in the previous example with a strong password that meets your security requirements.

j. Set the network interface.
Note that the last parameter is the Internet Gateway.

```
apicup iface create port portal1.sample.example.com eth0 192.168.1.107/255.255.255.0 192.168.1.2
apicup iface create port portal2.sample.example.com eth0 192.168.1.108/255.255.255.0 192.168.1.2
apicup iface create port portal3.sample.example.com eth0 192.168.1.109/255.255.255.0 192.168.1.2
```

k. Check the host configuration for problems.

```
apicup hosts list port
```

l. Validate the installation.

```
apicup subsys get port --validate
```

m. Create an ISO file in a plan folder. For example, **portplan-out**.

```
apicup subsys install port --out portplan-out
```

If you have multiple nodes listed for the hosts, when you run the **--out** command, it creates an ISO for each node. When deploying the nodes from VMware, each node gets its own ISO file attached.

n. To deploy the ISOs, see Deploying the portal subsystem OVA.

Overriding NTP server configuration

Override the hostname set for the NTP server on your VMs.

About this task

If you did not specify your NTP server during installation, or you want to change the configuration, then follow the steps in this topic.

Important: All API Connect subsystems must set their time from the same NTP server. Repeat these steps on all subsystem VMs in your deployment.

Procedure

1. Log in to each API Connect VM.

```
ssh apicadm@<hostname>
```

2. If the directory /etc/systemd/timesyncd.conf.d does not exist, then create it.

```
sudo mkdir /etc/systemd/timesyncd.conf.d
```

3. Edit the file /etc/systemd/timesyncd.conf.d/cloud-init.conf. If this file does not exist, then create it.

```
sudo vi /etc/systemd/timesyncd.conf.d/cloud-init.conf
```

4. Set the contents of the cloud-init.conf file as shown:

```
[Time]

NTP=<ntp server hostname>
```

5. Restart the `timesyncd` service.

```
sudo systemctl restart systemd-timesyncd
```

6. Verify the connection to the NTP server.

```
sudo journalctl -u systemd-timesyncd
```

7. Exit the VM, and from your project directory, update the `cloud_init` configuration and ISO files with your new NTP setting.
   a. Create a file called cloud-init.yaml (if it does not already exist) and paste in the details of your NTP server.

```
ntp:
  enabled: true
  ntp_client: systemd-timesyncd
  servers:
    - ntp.example.com
```

   b. Set `additional-cloud-init-file` to your cloud-init.yaml file.

```
apicup subsys set <subsys> additional-cloud-init-file cloud-init.yaml
```

Note: Updating the project directory `cloud_init` configuration with your new NTP settings is necessary so that if you encounter a disaster recovery situation (where you must re-create the ISO files and redeploy API Connect), your new deployment does not use your old NTP configuration.

Configuring SSHD to limit access to your deployment

How to configure SSHD in order to limit host access to your VMware deployment, or to change the SSHD cipher level.

About this task

The following instructions show how to configure SSHD in order to limit VMware access to a certain set of IP addresses, and how to change the SSHD cipher level.

Attention:

- SSHD configuration settings are not included in the IBM® API Connect backups. However, the settings are kept when you upgrade to a new fix pack.
- If you change the SSHD cipher level, and encounter issues with the new configuration, you must revert your cipher changes and retest. If after the retest with the original cipher level that came with IBM API Connect you still have issues, contact IBM Support.

Procedure

- The following instructions show you how to configure SSHD in order to limit VMware access to a certain set of IP addresses.
  1. Log in to the target virtual machine by using an SSH tool, and switch to the root user. For example, to log in to the Management subsystem, run the following commands:

```
ssh ip_address -l apicadm
sudo -i
```

  2. Move to the following folder:

```
/etc/ssh/sshd_config.d
```

  3. Create a new configuration file with the extension .conf that contains the IP address of the host that you want to allow to access your deployment. For example, to create the file run the following command:

```
vi filename.conf
```

     Then, edit the file by using the following format, which in this example is allowing users from IP address `123.135.1.2`:

```
AllowUsers *@123.135.1.2
```

     Additional hosts can be added by separating the IP address patterns with a space. For example:

```
AllowUsers *@123.135.1.2 *@135.168.1.2
```

  4. Restart the SSHD service by running the following command:

```
systemctl restart sshd.service
```

- The following instructions show you how to modify the cryptographic ciphers or algorithms in use by SSHD.
  1. Log in to the target virtual machine by using an SSH tool, and switch to the root user. For example, to log in to the Management subsystem, run the following commands:

```
ssh ip_address -l apicadm
sudo -i
```

  2. Move to the following folder:

```
/etc/ssh/sshd_config.d
```

  3. Create a new configuration file with the extension .conf that contains the list of ciphers and algorithms that you want to support.

For example, if you want to remove the 128 bit UMAC cipher from the following list of currently supported ciphers:

```
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256,umac-128@openssh.com
```

Create the .conf file by running the following command:

```
vi filename.conf
```

Then, remove that cipher from the list by adding the following line to the file:

```
MACs hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com,hmac-sha2-512,hmac-sha2-256
```

4. Restart the SSHD service by running the following command:

```
systemctl restart sshd.service
```

Results

Your SSHD configuration is updated to limit access to your VMware to a certain set of IP addresses, or to change the cipher level.

Enabling Developer Portal feature flags on VMware

Use a template override to update the installation CR with settings that control the default behavior of the Developer Portal subsystem.

About this task

You can add a template override to the Developer Portal subsystem CR to change the default behavior of the Portal subsystem, or to turn specific features on and off. Table 1 describes the available feature flags.

Table 1. List of available feature flags for the Developer Portal

Feature flag name	Default Value	Pod	Container	Description

`PORTAL_SKIP_WEB_ENDPOINT_VALIDATION`	`true`	`www`	`admin`	Controls whether the Portal subsystem checks whether the Portal web endpoint is accessible.
				
				Sometimes, the endpoint cannot be reached, for example due to the complexity of the networks. In which case the following type of error can be seen in the `portal-www` pod, and `admin` container logs:
				
				`An error occurred contacting the provided portal web endpoint: example.com`
				`The provided Portal web endpoint example.com returned HTTP status code 504`
				
				You can disable the check by setting this flag to `false`.

`ENABLE_TRUSTED_REVERSE_PROXY`	`false`	`www`	`admin`	Controls whether the Drupal `trusted_reverse_proxy` module can manage the reverse proxies list.
				
				If you have multiple load balancers and reverse proxies in your upstream network, and the perimeter module is triggered, the incorrect IP address might be banned rather than the intended client IP address. However, you can manage which IP addresses are banned by using the Drupal `trusted_reverse_proxy` module, and setting this feature flag to `true`.
				
				The Drupal module inspects the `x-forwarded-for` headers to identify the reverse proxies, and trusts that the first IP address found in the list is the client IP. For example, in `X-Forwarded-For: <client>, <proxy1>, <proxy2>`, the client IP `<client>` will be banned. For more information about this module, see https://www.drupal.org/project/trusted_reverse_proxy.
				
				To use this module, you must ensure that all of the proxies in your upstream network, including the ingress controller, are configured correctly so that the `x-forwarded-for` header is passed through to the `portal-www` pod. For example, the default behavior of the `nginx-ingress-controller` is to ignore the inbound `x-forwarded-for` header, and create a new one. To change this behavior, update the `nginx-ingress-controller` `configmap` with the following information:
				
				`data:`
				`  compute-full-forwarded-for: "true"`
				`  use-forwarded-headers: "true"`
				
				Warning: Enable this feature flag only if you trust your upstream reverse proxies, as it is possible to trick the `x-forwarded-for` header.

Procedure

1. Create an `extra-values.yaml` file, or open an existing `extra-values.yaml` file.
2. In the file, append the feature flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the `trusted_reverse_proxy` feature on all possible UI pages.

```
spec:
  template:
```

```
  - containers:
    - env:
       - name: ENABLE_TRUSTED_REVERSE_PROXY
         value: "true"
       name: container
    name: pod
```

Where:

- `container` is the name of the portal container.
- `pod` is the name of the portal pod.

Note: You can add multiple feature flags to the file.

3. Save the file.
4. Run the following command to set the `extra-values.yaml` file:

   ```
   apicup subsys set <portal_subsystem> extra-values-file <path_to_portal_extra-values.yaml_file>
   ```

5. Apply the overrides to the portal subsystem by running the following command:

   ```
   apicup subsys install <SUBSYSTEM_NAME>
   ```

   The Developer Portal subsystem is updated to enable or disable features as specified.

Specifying a range of allowable client IP addresses for the portal

Specify the range of client IP addresses to be allowed in a deployment of the portal

About this task

Use an extra-values-file to provide the allowlist of IP address.

Procedure

In your project directory, create a file called `ptl-extra-values.yaml`. For example:

```
spec:
  portalUIEndpoint:
      annotations:
        ingress.kubernetes.io/whitelist-source-range: 1.2.88.0/24
```

In this example, `1.2.88.0/24` is the acceptable range of client IP addresses.

Note: Depending on your network configuration for the forwarding of client IP addresses, you might need to run several test iterations to work out which client IP addresses to include in the list.

Managing an appliance data disk

You can use `apic` commands to manage appliance data disks in your VMware deployment.

The API Connect deployment on VMware uses 2 partitions. The first contains the base operating system, while the second is encrypted so that any customer data that is stored on disk uses the encrypted volume. Encryption is done with Linux Unified Key Setup (LUKS) disk encryption.

During installation of each API Connect subsystem, you specify a password `HD-PASSWD` when configuring the host:

```
apicup hosts create <SUBSYS> <HOSTNAME> <HD-PASSWD>
```

If you want to force a restart of processes, without requiring a full restart of the virtual machine, you can use the command `apic lock` to stop the Kubernetes node on the virtual machine and lock the secured storage. When you are ready to restart processes, you can use `apic unlock` to restart the Kubernetes node. The command `apic unlock` uses the password to unlock the partition so that files can be read from it and written to it. The unlock command also starts the `apic` daemon, also known as the `appliance-manager` service.

You can check that status of this service with:

```
sudo systemctl status appliance-manager
```

One `appliance-manager` daemon runs on each node, where it manages the Kubernetes cluster, processes update and upgrade requests, and gathers logs.

`apic` command	Description
`lock`	Shut down appliance services and lock the secured storage
`logs`	Retrieve logs from all nodes in the cluster
`status`	Report on cluster status
`unlock`	Unlock the secure storage and start the appliance
`version`	Get the API Connect appliance base version

Replica override for microservices on VMware

Modify the replica count for microservices by using template overrides for Custom Resources.

When API Connect is deployed, the deployment profile you select drives the number of replicas to be used for most deployment. For one replica profiles, specified by`n1x....`, the replica count is 1. For three replica profiles, specified by `n3x...`, the replica count is 3.

You can override the replica count for individual deployments by using template overrides.

- Template overrides are a piece of yaml that should be added to the Kubernetes custom resource. The examples provided in this topic show only that the `template:` element should be under the main `spec:` element of a CR. The rest of the CR is not shown.
- When applying overrides for Appliance deployments (virtual machines), the yaml sample provided as example must be added in an extra-values-file for the subsystem. To view an example of documenting a template override for an Appliance, see Setting rate limits for public APIs on the management service

Management subsystem

For a Management CR in Kubernetes or OpenShift, the following override specifies 5 replicas for the `apim` deployment:

```
spec:
  template:
  - name: apim
    replicaCount: 5
```

You can also configure replicate count through a similar template override for:

- `juhu`
- `ldap`
- `lur`

Analytics subsystem

The Analytics microservices that can be scaled using template override are:

- `ingestion`
- `mtls-gw`
- `storage-shared`
  Note that this microservice cannot be scaled below 2 replicas when using a three replica deployment profile.

Testing a new configuration against a current cluster

You can use the `apicup` utility to test the validity of a new configuration before you install it.

The `apicup` utility is used to set configuration properties for subsystems on API Connect on VMware appliances. The utility can be used for installation, upgrade, and maintenance activities such as backup and restore.

The usage pattern is to set values for each parameter you need for a subsystem, and then deploy the new values with the `apicup subsys install` command.

You can use the `--dry-run` option to test the validity of your values prior to deploying them to an existing cluster:

`apicup subsys install <subsystem_name> --dry-run`

Important: You cannot use `apicup subsys install <SUBSYS> --dry-run` for a fresh install or an upgrade. The `--dry-run` feature is for testing proposed configuration changes on an existing cluster.
For example, if you want to configure S3 backups for you management subsystem, the command flow is:

1. Follow the instructions for configuring management database backups Configuring management database backups by issuing the required `apicup subsys set` commands:

   ```
   apicup subsys set mgmt <setting>=<value>
   apicup subsys set mgmt <second_setting>=<value>
   apicup subsys set mgmt <third_setting>=<value>
   .
   .
   .
   ```

2. Do a dry run of the install command:

   `apicup subsys install mgmt --dry-run`

   Example message on success:

   `managementcluster.management.apiconnect.ibm.com/management configured (server dry run)`

   Example message on failure:

   `Error: Failed to execute dry-run:....`

   The error message also contains details about the error.

3. When dry run returns success, deploy:

   `apicup subsys install mgmt`

TLS certificate concepts and operations

Information about internal API Connect certificates, renewing expired certificates, exporting certificates, and other certificate maintenance operations.

This topic covers advanced certificate configuration procedures that are not required in day-to-day API Connect operations. For best practices relating to API Connect certificates, see API Connect TLS certificate best practices.

API Connect certificate types

All TLS certificates that are generated and used by API Connect fall into one of the following categories:

- CA certificates - API Connect creates self-signed CA certificates to sign all the API Connect end-entity certificates. The CA certificates are:
  - **`ingress-ca`** - used by the ingress-issuer. The ingress-ca signs all user-facing and inter-subsystem certificates.
  - **`root-ca`** - a self-signed root certificate that signs the **`ingress-ca`** certificate.
  - **`management-ca`** - signs all the management intra-subsystem certificates.
  - **`portal-ca`** - signs all the portal intra-subsystem certificates.
  - **`analytics-ca`** - signs all the analytics intra-subsystem certificates.

  CA certificates have a default duration of 10 years.
  Do not customize CA certificates. The only scenarios when CA certificates require updating are:
  - Expiry, after 10 years.
  - Synchronizing the **`ingress-ca`** certificate between data centers in multiple data center deployments.
- Ingress certificates - Ingress certificates are end-entity certificates that are signed by the **`ingress-ca`** certificate and secure the API Connect endpoints. Ingress certificates are divided into two types:
  - Inter-subsystem certificates - certificates that are used to secure the communication between API Connect subsystems, for example between the management subsystem and gateway. By default, communication between most subsystems uses mTLS. It is possible to use JWT instead of mTLS: Using JWT instead of mTLS on OVA.
    Do not customize inter-subsystem certificates.
  - User-facing certificates - certificates that API Connect users see when they interact with the API Connect UIs and REST API.
    You can customize your user-facing certificates: Customizing your user-facing certificates

  All the ingress certificates have a duration of 2 years.
- Intra-subsystem certificates - certificates that are used between software components in the same subsystem. Intra-subsystem certificates are signed by a subsystem specific CA certificate: **`management-ca`**, **`portal-ca`**, **`analytics-ca`**. The gateway subsystem is a single pod, and has no intra-subsystem certificates.
  Do not customize intra-subsystem certificates.

Note: The inter and intra-subsystem certificates use of a self-signed root CA presents no security risk. For internal communications with a limited number of predefined endpoints, use of locally generated self-signed CA certificates can be more secure than external CA certificates, as certificates are only ever issued for the known components and the domain of trust is kept as small as possible.

- **Certificate validation reference**
  Certificates validation errors reference table.

Certificate reference VMware

Details of all API Connect TLS certificates on VMware.

The **apicup certs list** command returns all the API Connect TLS certificates that can be configured with the **apicup** command.
Note: The **apicup certs list** command also returns credentials and encryption secrets that are used by API Connect. For information about these secrets and credentials, see Credentials and encryption secrets reference.
Add the flag **`--endpoints`** to see only user-facing endpoint certificates. Add the flag **`--creds`** to see only credentials and encryption secrets.

Common certificates

Common certificates exist in all subsystems of an API Connect deployment, and must be identical in each subsystem to enable them to communicate with each other.

Because you deploy your API Connect subsystems from a single project directory, these certificates are automatically set to be the same on all subsystems.

Do not customize any of the common certificates.

Table 1. Common certificates

Certificate name	Description
`root-ca`	CA certificate that is the root of the certificate chain for all other API Connect certificates. Do not update this certificate.

Certificate name	Description
`ingress-ca`	Intermediate CA certificate used to generate all API Connect ingress certificates. Do not customize this certificate. If the certificate expires (duration is 20 years), see: Renewing ingress-ca. If you have multiple data centers that are managed from different project directories, you can synchronize this certificate, see: Synchronizing the ingress-ca certificate.
`appliance-client`	A client certificate that is used by the **apicup** command to communicate with the API Connect subsystem appliances. Requires EKU `clientAuth`. Do not update this certificate.
`k8s-ca`	CA certificate that forms the root of the certificate chain for the Kubernetes cluster components that run in the API Connect subsystem appliance. Do not update this certificate.

Management certificates

The following table lists the certificates that exist on the management subsystem, in addition to the common certificates.

Table 2. Management subsystem certificates

Certificate name	Description
`portal-client`	The `portal-client` certificate is an inter-subsystem ingress certificate that is presented to the developer portal subsystem during portal service registration. For successful portal registration the `portal-client` certificate must meet these requirements: • Specify EKU `clientAuth`. • Signed by the same CA (`ingress-ca`) as the `portal-admin-ingress` certificate that secures the admin endpoint on the developer portal. • The subject name must match the `adminClientSubjectDN` in the portal subsystem. If you have a multiple data center deployment, both data centers must use an identical subject name. This certificate is loaded by the management subsystem into the `Portal Director TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the portal, then create a new profile and specify it when you register the portal service. Do not update this certificate.
`analytics-client-client`	A legacy certificate, it is not used from v10.0.5 onwards.
`analytics-ingestion-client`	The `analytics-ingestion-client` certificate is an inter-subsystem ingress certificate that is presented to the analytics subsystem during analytics service registration. For successful analytics registration the `analytics-ingestion-client` certificate must meet these requirements: • Specify EKU `clientAuth`. • Signed by the same CA (`ingress-ca`) as the `analytics-ingestion-ingress` certificate that secures the ingestion endpoint on the analytics subsystem. • The subject name must match the `clientSubjectDN` in the analytics subsystem. `analytics-ingestion-client` is also used by the gateway subsystem to authenticate with the analytics ingestion endpoint, for the transmission of API event data. This certificate is loaded by the management subsystem into the `Analytics ingestion TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the analytics subsystem, then create a new profile and specify it when you register the analytics service. For multiple data center deployments, both data centers must have an identical subject name. Do not update this certificate.
`platform-api`	The `platform-api` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope. The endpoint in the management subsystem configuration uses the same name: `platform-api` The hostnames for which the certificate is valid must include the `platform-api` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`consumer-api`	The `consumer-api` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope. The endpoint in the management subsystem configuration uses the same name: `consumer-api` The hostnames for which the certificate is valid must include the `consumer-api` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.

Certificate name	Description
`api-manager-ui`	The **`api-manager-ui`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI. The endpoint in the management subsystem configuration uses the same name: **`api-manager-ui`**. The hostnames for which the certificate is valid must include the **`api-manager-ui`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`cloud-admin-ui`	The **`cloud-admin-ui`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI. The endpoint in the management subsystem configuration uses the same name: **`cloud-admin-ui`**. The hostnames for which the certificate is valid must include the **`cloud-admin-ui`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`hub`	Used by the Automated API behavior testing application. User-facing ingress certificate for the **`hub-endpoint`**.
`management-replication-client`	Used in 2DCDR deployments only. The **`management-replication-client`** certificate is an inter-subsystem ingress client certificate that is used when connecting to the **`management-replication`** endpoint in the other data center. Requires EKU **`clientAuth`**.
`management-replication-ingress`	Used in 2DCDR deployments only. The **`management-replication-ingress`** certificate is an inter-subsystem ingress server certificate that is used to secure the **`management-replication`** endpoint. `management-replication-ingress` must be valid for the endpoint defined by `apicup subsys set <subsystem> management-replication=<endpoint>` Requires EKU **`serverAuth`**.

Portal subsystem certificates

The following table lists the certificates that exist on the management subsystem, in addition to the common certificates.

Table 3. Portal subsystem certificates

Certificate name	Description
`mgmt-consumer-api`	The **`mgmt-consumer-api`** certificate is an inter-subsystem ingress certificate that secures the consumer API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the **`consumer-api`** certificate in the management subsystem. Do not update this certificate.
`mgmt-platform-api`	The **`mgmt-platform-api`** certificate is an inter-subsystem ingress certificate that secures the platform API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the **`platform-api`** certificate in the management subsystem. Do not update this certificate.
`portal-admin-ingress`	The **`portal-admin-ingress`** certificate is an inter-subsystem ingress certificate that is used to secure the portal administration endpoint. The management subsystem communicates with this endpoint to register the portal and to send portal configuration updates. Do not update this certificate.
`portal-replication-client`	Used in 2DCDR deployments only. The **`portal-replication-client`** certificate is an inter-subsystem ingress client certificate that is used when connecting to the **`portal-replication`** endpoint in the other data center. Requires EKU **`clientAuth`**.
`portal-replication-ingress`	Used in 2DCDR deployments only. The **`portal-replication-ingress`** certificate is an inter-subsystem ingress server certificate that is used to secure the **`portal-replication`** endpoint. `portal-replication-ingress` must be valid for the endpoint defined by `apicup subsys set <subsystem> portal-replication=<endpoint>` Requires EKU **`serverAuth`**.
`portal-www-ingress`	The **`portal-www-ingress`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites. The endpoint is called **`portal-www`** in the portal subsystem configuration.

Analytics subsystem certificates

The following table lists the certificates that exist on the management subsystem, in addition to the common certificates.

Table 4. Analytics subsystem certificates

Certificate name	Description
`analytics-ca`	Internal certificate used for communication between analytics subsystem components. Do not update this certificate.
`analytics-ingestion-ingress`	The `analytics-ingestion-ingress` certificate is an inter-subsystem ingress certificate that is used to secure the analytics ingestion endpoint, which is used for the following: • Receiving API event data from associated gateways. • Configuration and analytics queries from the management subsystem. Do not update this certificate.
`service-client`	Internal certificate used for communication between analytics subsystem components. Do not update this certificate.
`service-server`	Internal certificate used for communication between analytics subsystem components. Do not update this certificate.

Ingress certificates

The following table lists all the certificates across all subsystems that are signed by the `ingress-ca`. If you renew your `ingress-ca` certificate, then you must also renew all the ingress end-entity certificates that are listed in this table. For steps on renewing the `ingress-ca`, see Renewing ingress-ca.

Table 5. Certificates signed by `ingress-ca`

Certificate name	Description
`portal-client`	The `portal-client` certificate is an inter-subsystem ingress certificate that is presented to the developer portal subsystem during portal service registration. For successful portal registration the `portal-client` certificate must meet these requirements: • Specify EKU `clientAuth`. • Signed by the same CA (`ingress-ca`) as the `portal-admin-ingress` certificate that secures the admin endpoint on the developer portal. • The subject name must match the `adminClientSubjectDN` in the portal subsystem. If you have a multiple data center deployment, both data centers must use an identical subject name. This certificate is loaded by the management subsystem into the `Portal Director TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the portal, then create a new profile and specify it when you register the portal service. Do not update this certificate.
`analytics-client-client`	A legacy certificate, it is not used from v10.0.5 onwards.
`analytics-ingestion-client`	The `analytics-ingestion-client` certificate is an inter-subsystem ingress certificate that is presented to the analytics subsystem during analytics service registration. For successful analytics registration the `analytics-ingestion-client` certificate must meet these requirements: • Specify EKU `clientAuth`. • Signed by the same CA (`ingress-ca`) as the `analytics-ingestion-ingress` certificate that secures the ingestion endpoint on the analytics subsystem. • The subject name must match the `clientSubjectDN` in the analytics subsystem. `analytics-ingestion-client` is also used by the gateway subsystem to authenticate with the analytics ingestion endpoint, for the transmission of API event data. This certificate is loaded by the management subsystem into the `Analytics ingestion TLS client profile` that you can see in the Cloud Manager UI (see TLS profiles). If you want the management subsystem to present a different client certificate to the analytics subsystem, then create a new profile and specify it when you register the analytics service. For multiple data center deployments, both data centers must have an identical subject name. Do not update this certificate.
`platform-api`	The `platform-api` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope. The endpoint in the management subsystem configuration uses the same name: `platform-api` The hostnames for which the certificate is valid must include the `platform-api` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.
`consumer-api`	The `consumer-api` certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope. The endpoint in the management subsystem configuration uses the same name: `consumer-api` The hostnames for which the certificate is valid must include the `consumer-api` endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU `serverAuth`.

Certificate name	Description
api-manager-ui	The **api-manager-ui** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI. The endpoint in the management subsystem configuration uses the same name: **api-manager-ui**. The hostnames for which the certificate is valid must include the **api-manager-ui** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **serverAuth**.
cloud-admin-ui	The **cloud-admin-ui** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI. The endpoint in the management subsystem configuration uses the same name: **cloud-admin-ui**. The hostnames for which the certificate is valid must include the **cloud-admin-ui** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **serverAuth**.
hub	Used by the Automated API behavior testing application. User-facing ingress certificate for the **hub-endpoint**.
portal-admin-ingress	The **portal-admin-ingress** certificate is an inter-subsystem ingress certificate that is used to secure the portal administration endpoint. The management subsystem communicates with this endpoint to register the portal and to send portal configuration updates. Do not update this certificate.
portal-www-ingress	The **portal-www-ingress** certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites. The endpoint is called **portal-www** in the portal subsystem configuration.
analytics-ingestion-ingress	The **analytics-ingestion-ingress** certificate is an inter-subsystem ingress certificate that is used to secure the analytics ingestion endpoint, which is used for the following: • Receiving API event data from associated gateways. • Configuration and analytics queries from the management subsystem. Do not update this certificate.
management-replication-client	Used in 2DCDR deployments only. The **management-replication-client** certificate is an inter-subsystem ingress client certificate that is used when connecting to the **management-replication** endpoint in the other data center. Requires EKU **clientAuth**.
management-replication-ingress	Used in 2DCDR deployments only. The **management-replication-ingress** certificate is an inter-subsystem ingress server certificate that is used to secure the **management-replication** endpoint. **management-replication-ingress** must be valid for the endpoint defined by **apicup subsys set *<subsystem>* management-replication=*<endpoint>*** Requires EKU **serverAuth**.
mgmt-consumer-api	The **mgmt-consumer-api** certificate is an inter-subsystem ingress certificate that secures the consumer API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the **consumer-api** certificate in the management subsystem. Do not update this certificate.
mgmt-platform-api	The **mgmt-platform-api** certificate is an inter-subsystem ingress certificate that secures the platform API endpoint on the management subsystem. The portal has a copy of this certificate so it can verify that it is communicating with the management subsystem. This certificate must be identical to the **platform-api** certificate in the management subsystem. Do not update this certificate.
portal-replication-client	Used in 2DCDR deployments only. The **portal-replication-client** certificate is an inter-subsystem ingress client certificate that is used when connecting to the **portal-replication** endpoint in the other data center. Requires EKU **clientAuth**.
portal-replication-ingress	Used in 2DCDR deployments only. The **portal-replication-ingress** certificate is an inter-subsystem ingress server certificate that is used to secure the **portal-replication** endpoint. **portal-replication-ingress** must be valid for the endpoint defined by **apicup subsys set *<subsystem>* portal-replication=*<endpoint>*** Requires EKU **serverAuth**.

User-facing certificates

The following table lists all the certificates that are used for user-facing endpoints.

Table 6. User-facing endpoint certificates.

Certificate name	Description
`portal-www-ingress`	The **`portal-www-ingress`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access developer portal sites. The endpoint is called **`portal-www`** in the portal subsystem configuration.
`api-manager-ui`	The **`api-manager-ui`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Manager UI. The endpoint in the management subsystem configuration uses the same name: **`api-manager-ui`**. The hostnames for which the certificate is valid must include the **`api-manager-ui`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`cloud-admin-ui`	The **`cloud-admin-ui`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the Cloud Manager UI. The endpoint in the management subsystem configuration uses the same name: **`cloud-admin-ui`**. The hostnames for which the certificate is valid must include the **`cloud-admin-ui`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`consumer-api`	The **`consumer-api`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at organization scope. The endpoint in the management subsystem configuration uses the same name: **`consumer-api`** The hostnames for which the certificate is valid must include the **`consumer-api`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`platform-api`	The **`platform-api`** certificate is a user-facing ingress certificate that is returned to users when they attempt to access the API Connect REST API at cloud scope. The endpoint in the management subsystem configuration uses the same name: **`platform-api`** The hostnames for which the certificate is valid must include the **`platform-api`** endpoint. A wildcard certificate can be used as the first element in a hostname, for example, if the endpoint is: *store.acme.com*, the certificate can be one that is valid for hostnames that match **.acme.com*. Requires EKU **`serverAuth`**.
`hub`	Used by the Automated API behavior testing application. User-facing ingress certificate for the **`hub-endpoint`**.

Customizing user-facing certificates

How to set the user-facing endpoints of API Connect to use your own TLS server certificates.

Before you begin

Identify the user-facing certificates that you want to customize: Table 6.

Ensure that you have certificate, key, and CA PEM files for each certificate you want to customize. The PEM files must not be password-protected.

For example, to customize the certificate that secures the Cloud Manager UI, you must have the following PEM files: cloud-admin-ui-cert.pem, cloud-admin-ui-key.pem, cloud-admin-ui-ca.pem

User-facing certificates must meet the following requirements:

- Specify Extended Key Usage (EKU) of **`serverAuth`**.
- Include the Subject Alternative Name (SAN) of the endpoint that they secure.
- If the certificate is signed by an intermediate CA, then the ca.pem file must contain the full chain to root CA.

About this task

You update the user-facing certificates with the **apicup** command.

You can set custom user-facing certificates during installation, or you can update them after installation, replacing the default certificates that are generated.

Note: API Connect verifies certificates when you set them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your custom certificates before they expire.

Procedure

1. If you are updating a user-facing certificate after installation, you must first clear the default certificate that was created:

   ```
   apicup certs set <subsystem name> <certificate name> --clear
   ```

   For example, to clear the certificate that secures the Cloud Manager UI:

   ```
   apicup certs set mgmt cloud-admin-ui --clear
   ```

2. Set the user-facing certificate with the **apicup certs set** command, supplying the PEM files for your new certificate:

```
apicup certs set <subsystem name> <certificate name> <cert file> <key_file> <ca file>
```

For example:

```
apicup certs set mgmt cloud-admin-ui cert.pem key.pem ca.pem
```

3. If you are updating the certificate after installation, then apply the update with `apicup subsys install`

```
apicup subsys install <subsystem name>
```

4. You can verify that the certificate is updated with **apicup certs list --endpoints**:

```
apicup certs list <subsystem name> --endpoints
```

Example output:

```
Common certificates
===================

Name                        Summary                                                                 Validation errors
----                        -------                                                                 -----------------
...

Subsystem def-management certificates
=====================================

Name                              Summary                                                           Validation errors
----                              -------                                                           -----------------
...
cloud-admin-ui                    CN: cloud-admin-ui
                                  SubjectKeyId: 9E:8B:FA:7E:92:70:EC:86:2F:C3:3A:20:E8:13:EA:F4
                                  AuthorityKeyId: E4:AB:09:FF:A9:7D:D3:70:DD:AD:69:C4:A4:34:8D:96
...
```

Note: Along with the user-facing certificates, the **apicup certs list** (without `--endpoints` flag) command outputs details of other internal API Connect certificates and secrets that you should not update.

Certificate expiry and renewal

How to renew and replace TLS certificates in your VMware deployment.

The instructions in this topic apply only to the management, portal, and analytics subsystems. For gateway appliance-specific instructions, see *Configuring the API Connect Gateway Service* in the appropriate version of the DataPower documentation.
Note: The API invocation certificate (the certificate that is presented to callers of your APIs) is configured in the Cloud Manager UI when you register your gateway services. For more information about API invocation certificates, see Registering a gateway service and TLS profiles overview.
All ingress certificates in API Connect have a duration of 2 years. To avoid an outage when they expire, they must be manually renewed before expiration.

The `ingress-ca` CA certificate has a duration of 10 years and also requires manual steps to renew it before expiry.

Intra-subsystem certificates are renewed automatically.

If you have a two data center disaster recovery deployment, then when you renew certificates in one data center, you must copy the renewed certificates to the other data center. See Extracting and copying certificates.

Identifying expired certificates

To identify expired certificates, run:

```
apicup certs list <subsystem>
```

Any certificates that are expired or near to expiry are indicated in the `Validation errors` column.
Follow the step in Renewing certificates to renew expired or nearly expired certificates.

Renewing certificates

Use the **apicup** command to renew certificates.
Warning: Use these steps to renew only end-entity ingress certificates as defined here: ingress certificates. If you want to renew the `ingress-ca` certificate, then see Renewing ingress-ca.

1. Clear the existing certificate with the `apicup certs clear` command:

```
apicup certs set --clear <subsystem> <certificate name>
```

Repeat for all ingress certificates that you want to renew.
2. Generate new certificates for all the certificates that you cleared in step 1:

```
apicup certs generate <subsystem>
```

You do not need to specify the certificates with the **apicup certs generate**, the command identifies all empty (cleared) certificates in the subsystem and generates new ones.
3. Apply the updated certificates to the subsystem:

```
apicup subsys install <subsystem>
```

Renewing `ingress-ca`

Use the **apicup** command to renew **`ingress-ca`**, and then renew all the end-entity certificates the are signed by **`ingress-ca`**.

1. Clear the **`ingress-ca`** certificate:

   ```
   apicup certs set --clear <management subsystem> ingress-ca
   ```

   Although this command specifies *<management subsystem>*, because **`ingress-ca`** is a common certificate, it is cleared for all subsystems. You do not need to repeat this command for every portal or analytics subsystem that is managed from the same project directory.

2. Generate a new **`ingress-ca`**:

   ```
   apicup certs generate <subsystem>
   ```

   The **generate** command creates certificates for all previously cleared certificates, you do not need to specify **`ingress-ca`** in this command.
3. Clear all the ingress end-entity certificates that are signed by **`ingress-ca`**:

   ```
   apicup certs set --clear <subsystem> <certificate name>
   ```

   For a list of the ingress certificates, see Ingress certificates.
4. Generate new ingress end-entity certificates for each subsystem:

   ```
   apicup certs generate <subsystem>
   ```

5. Apply the updated certificates to all subsystems:

   ```
   apicup subsys install <subsystem>
   ```

Extracting and copying certificates

How to extract certificate contents and apply them to API Connect subsystems in other environments.

If you have a two data center disaster recovery deployment, or have API Connect subsystems in different data centers that are managed by different project directories, then it is necessary to manually synchronize the TLS certificates between the environments.

Synchronizing the `ingress-ca` certificate

To export the **`ingress-ca`** certificate from your target environment, follow these steps:

1. Extract the **`ingress-ca`** public certificate to a file called ingress-ca-cert.pem

   ```
   apicup certs get <subsystem> ingress-ca > ingress-ca-cert.pem
   ```

2. Extract the **`ingress-ca`** private key to a file called ingress-ca-key.pem

   ```
   apicup certs get <subsystem> ingress-ca -t key > ingress-ca-key.pem
   ```

3. Extract the **`ingress-ca`** CA to a file called ingress-ca-CA.pem

   ```
   apicup certs get <subsystem> ingress-ca -t ca > ingress-ca-CA.pem
   ```

Note: The **`ingress-ca`** certificate is the same for all subsystems that are managed from the same project directory, so you can specify any subsystem in the **apicup certs get** command.
To apply the exported **`ingress-ca`** certificate to another environment, follow these steps:

1. Apply the exported certificate files to the **`ingress-ca`**:

   ```
   apicup certs set <subsystem> ingress-ca ingress-ca-cert.pem ingress-ca-key.pem ingress-ca-CA.pem
   ```

   Note: The **`ingress-ca`** certificate is the same for all subsystems that are managed from the same project directory, so you can specify any subsystem in the **apicup certs set** command.
2. Clear all the ingress end-entity certificates that are signed by **`ingress-ca`**:

   ```
   apicup certs set --clear <subsystem> <certificate name>
   ```

   For a list of the ingress certificates, see Ingress certificates.
3. Generate new ingress end-entity certificates for each subsystem:

   ```
   apicup certs generate <subsystem>
   ```

4. Apply the updated certificates to all subsystems:

   ```
   apicup subsys install <subsystem>
   ```

Rotating the portal intra-subsystem certificates on VMware

Use the **apicup** command to rotate the portal intra-subsystem certificates.

The portal's intra-subsystem certificates: **`portal-ca`**, **`portal-client`**, and **`portal-server`**, are not shown in the **apicup certs list** output, and cannot be updated with **apicup certs set**. If you want to renew these certificates, you can use the **`apicup subsys rotate-secrets`** command.

Warning: The portal intra-subsystem certificates are internal certificates that are created and renewed automatically. Renewing these certificates with **apicup subsys rotate-secrets** is only necessary in specific failure scenarios and should be done only if advised by IBM support.
To rotate the Developer Portal subsystem secrets, certificates, or both, run the following command:

```
apicup subsys rotate-secrets portal

Rotate portal subsystem secrets

Usage:
  apicup subsys rotate-secrets SUBSYS [flags]

Flags:
      --certs strings              List of certificates you want to rotate (Listing an issuer will rotate any certs issued by
the issuer e.g listing just portal-ca will rotate portal-ca, portal-client and portal-server)
      --encryption-secret string   Optional value to set the encryption secret to, if supplied secret exists in the env. If not
supplied the rotated secret will be random.
  -h, --help                       help for rotate-secrets
      --rotate-encryption-secret   Set to true if you want to rotate the encryption secret.
      --wait                       Wait for the operation to complete or fail.
      --wait-timeout duration      Command timeout in seconds. (default 40s)

Global Flags:
      --accept-license   Deprecated. Use apicup licenses commands to work with licenses
      --debug            Enable debug logging
```

For example, to rotate the encryption secret to a random value run the following command:
Note: This command is applicable for both standalone and 2DC environments.

```
apicup subsys rotate-secrets portal --rotate-encryption-secret true
```

The following example rotates the encryption secret to a named secret:
Note: You first must exec into the Developer Portal OVA to create the secret. This command is applicable for 2DC environment as well and the secret must be in the active environment for 2DC setup.

```
apicup subsys rotate-secrets portal --rotate-encryption-secret --encryption-secret my-new-secret
```

The following example rotates all of the Developer Portal certificates:

```
apicup subsys rotate-secrets portal --certs portal-ca
```

The following example rotates just the server and client certificates:

```
apicup subsys rotate-secrets portal --certs portal-server,portal-client
```

To list any Developer Portal secret rotations that were created by using the **rotate-secrets** command:

```
apicup subsys list-rotate-secrets portal --timeout 30
```

Where:

- *portal* is the name of your Developer Portal subsystem.
- **--timeout** (optional) is the duration in seconds of the command timeout. Default is 40 seconds.

To delete any Developer Portal secret rotations that were created by using the **rotate-secrets** command:

```
apicup subsys delete-rotate-secret portal --rotate-secret-name secret_name --wait true --wait-timeout 80

Delete a secret rotation of the subsystem

Usage:
  apicup subsys delete-rotate-secret SUBSYS [flags]

Flags:
  -h, --help                       help for delete-rotate-secret
      --rotate-secret-name string  Value of a Portal Secret Rotation CR name to delete.
      --wait                       Wait for the operation to complete or fail.
      --wait-timeout duration      Command timeout in seconds. (default 1m0s)

Global Flags:
      --accept-license   Deprecated. Use apicup licenses commands to work with licenses
      --debug            Enable debug logging
```

Updating the gateway peering certificate

How to update the certificate that is used to secure communication between gateways.

The behavior when you update the gateway peering certificate depends on the certificate type:

- Self-signed gateway peering certificate:
  Gateway downtime and a split-brain occurs when you rotate gateway peering certificate that is used by the **apic-gw-service**. When you change one of the peer group nodes, it is detached from the peer-group and becomes a stand-alone node (claiming itself a self-primary). The other nodes consider the node down until it is re-synced back.

- CA signed gateway peering certificate:
  To avoid downtime, create a crypto validation credential object that contains the certificate issuers. When the validation credential is placed in the peer-group, rotating a leaf certificate (that is signed by the same issuer) does not cause gateway-peering downtime or a split-brain. If you have a new issuer certificate, then the behavior is the same as with a self-signed certificate.

Apicup certs command reference

Documentation of the **apicup certs** command you use to manage API Connect TLS certificates and secrets.

The **apicup certs** command is used to set, clear, and generate the TLS certificates that are used by API Connect. The **apicup certs** command is also used to manage some of the secrets used by API Connect, such as remote backup server credentials and database encryption secrets.

After you modify certificates with the **apicup certs** command, you must apply the changes to your subsystems with:

```
apicup subsys install <subsystem name>
```

Setting and clearing certificates

Run the `apicup certs set` command:

Table 1. apicup certs set

Command	Values	Result
`apicup certs set SUBSYS CERT_NAME [CERT_FILE KEY_FILE CA_FILE] [flags]`	Parameters are: • SUBSYS - name of the subsystem to which the certificate applies • CERT_NAME - name of the certificate; see Certificate reference VMware for a list of certificates that can be set for each subsystem. • CERT_FILE - Path to the certificate file in PEM format. • KEY_FILE - Path to the private key file in PEM format. • CA_FILE - Path to the certificate authority (CA) file. The contents of the file might be the concatenation of an intermediate CA and the root CA (in that order). **Note:** When you set the `root-ca` certificate, omit the CA_FILE parameter.	Sets the specified certificate to be applied when **apicup subsys install** is run.
`apicup certs set SUBSYS CERT_NAME [KEY_FILE] [flags]`	KEY_FILE - The file that contains the encryption-secret for field level encryption in the management database. Applies only to the management subsystem . The certificate name is `encryption-secret`. The type is secure random bytes with a length of 128 bytes. For example, `apicup certs set mgmt1 encryption-secret /path/to/encryption-secret.bin`. **Note:** Do not specify any of the [CERT_FILE KEY_FILE CA_FILE] parameters when you set the encryption-secret.	Applies the `encryption-secret` when the management subsystem is installed.
`flags` • `--clear` • `--help`	Flags are: • --clear - Clears the specified certificate. For example, `apicup certs set mgmt1 encryption-secret --clear` • --help - Displays help for the command.	The specified certificate is cleared. When you make configuration changes such as changing endpoints, the corresponding certificate must be cleared so that a new certificate can be set.

Viewing details of a certificate

Run the `apicup certs get` command:

Table 2. apicup certs get

Command	Values	Result
`apicup certs get SUBSYS CERT_NAME [flags]`	Parameters are: • SUBSYS - name of the subsystem to which the certificate applies • CERT_NAME - name of the certificate to retrieve; see Certificate reference VMware for a list of certificates	Returns the specified certificate for the specified subsystem.
`flags` • `--output string` • `--type string` • `--help`	Flags are: • --output string- Specify a file for the retrieved values, or specify "-" to send to stdout. The default is "-" to send to stdout. For example, `apicup certs get mgmt1 --output myCertsFile` • --type string - Returns only the specified type. If not specified, the type is cert. For example, `apicup certs get mgmt1 --type ca` • --help - Displays help for the command.	• For --output: The specified certificate is retrieved and sent to stdout or saved to the specified file • For --type: Certificates are retrieved that match the type specified. .

List the certificates for a subsystem

Run the command **apicup certs list**:

Table 3. apicup certs list

Command	Values	Result
`apicup certs list SUBSYS [flags]`	Parameters are: • SUBSYS - name of the subsystem for which you want to list certificates	Returns a list of certificates that are configured for the subsystem.
`flags` • `--help` • `--endpoints` • `--creds`	Flags are: • --help - Displays help for the command. • --endpoints - Shows only user-facing endpoint certificates. • --creds - Shows only credentials.	

Generate certificates

The `apicup certs generate` command generates and sets default certificates. The `generate` command generates and sets a certificate only if it is not already set.

Note: The **apicup subsys install** operation also generates and sets any unset certificates, but use the `apicup certs generate` command so that you can set them and review them before you install.

Table 4. apicup certs generate

Command	Values	Result
`apicup certs generate SUBSYS [flags]`	Parameters are: • SUBSYS - name of the subsystem for which you want to generate certificates	Generates certificates that are currently not set for the subsystem. Generates self-signed certificates.
`flags` • `--help`	Flags are: • --help - Displays help for the command.	Help text is displayed.

Certificate validation reference

Certificates validation errors reference table.

The following table lists the certificate validation errors that the **apicup certs** command might report.

Validation	Messages	Error	Action to take
Verify that the certificate is set properly.	`certificate <cert> not set`	The certificate is not set.	
	`unable to load cert <cert>`	The certificate is set but cannot be read.	
Verify certificate key usage (Extended Key Usage).	`unable to verify cert <cert>: missing key usage <n>`	The certificate is missing the required key usage.	Check Certificate reference VMware to confirm the EKU required for the certificate.
Verify the certificate signing CA. If available, the CA file is loaded. Then the certificate is verified against the provided CA file, including enforcement of Extended Key Usage.	`unable to parse CA to verify cert <cert>`	The CA file could not be parsed and loaded.	
	`unable to verify cert <cert>`	The certificate failed verification against the provided CA file.	One possible reason for receiving this error is that the correct EKU is missing.
Verify certificate hosts.	`unable to verify cert <cert>: missing <host>`	The certificate is not valid for the required host.	See Certificate reference VMware for the required hosts.
Verify that a certificate that is being used as a CA is a CA certificate.	`unable to verify cert <cert>: certificate is not a CA`	The certificate is not a valid CA.	
Verify client certificate match. The `portal-client`, and `analytics-ingestion-client` certificates are verified against the CA of `portal-admin-ingress`, and `analytics-ingestion-ingress`.	`a CA certificate must be provided for this certificate`	The CA certificate is missing for one of the `portal-admin-ingress`, and `analytics-ingestion-ingress`.	The common certificates `portal-client`, and `analytics-ingestion-client` must be set before you set any custom certificates.
	`client cert cannot be verified against provided CA certificate`	The verification failed.	

Use JWT security instead of mTLS between subsystems

If your network requires TLS termination on load-balancers located between your API Connect subsystems, then disable mTLS and enable JWT to provide application layer security.

JWT security provides application layer security and can be used instead of mTLS when there are load-balancers located between subsystems that require TLS termination. For more information about JWT security, see Enable JWT instead of mTLS.

1. To enable JWT and disable mTLS, first identify the JWKS URL from the management subsystem:

```
apicup subsys get <management subsystem name>

...
jwks-url     https://appliance1.apic.acme.com/api/cloud/oauth2/certs  JWKS URL for Portal and analytics subsystems to
validate JWT -- this is unsettable and is generated based on the platform-api endpoint
...
```

2. Disable mTLS and enable JWT on portal and analytics by setting the `mtls-validate-client` and `jwks-url` values with **apicup**:

```
apicup subsys set <portal> mtls-validate-client=false
apicup subsys set <portal> jwks-url=appliance1.apic.acme.com/api/cloud/oauth2/certs

apicup subsys set <analytics> mtls-validate-client=false
apicup subsys set <analytics> jwks-url=appliance1.apic.acme.com/api/cloud/oauth2/certs
```

3. Apply the change to portal and analytics with `apicup subsys install`:

```
apicup subsys install <subsystem_name>
```

4. To enable JWT and disable mTLS on the gateway appliance, see *Configuring the API Connect gateway service* in the DataPower documentation.

Note: Do not disable mTLS without enabling JWT.

Credentials and encryption secrets reference

API Connect user credentials and database encryption secrets that are managed with the **apicup certs** command.

The **apicup certs** command is used to manage various credentials and encryption secrets that are used by API Connect management and portal subsystems.
Note: For details of the TLS certificates that you can manage with the **apicup certs** command, see Certificate reference VMware.

Management subsystem credentials and secrets

The following table lists all the secrets and credentials that are returned from the **apicup certs list <management subsystem>** command:

Table 1. Management subsystem credentials and secrets

Secret or credential name	Description
`atm-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`consumer-toolkit-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`consumer-ui-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`database-backup-auth-ssh-key`	SSH key for authentication with a remote SFTP backup server.
`designer-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`encryption-secret`	A 128-bytes long encryption secret that is used to do field level encryption in the management subsystem database. If you want to modify this credential, open a support case.
`juhu-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`toolkit-credential`	Credential used in internal API Connect communication. Do not modify this credential.
`ui-credential`	Credential used in internal API Connect communication. Do not modify this credential.

Portal subsystem credentials and secrets

The following table lists all the secrets and credentials that are returned from the **apicup certs list <portal subsystem>** command:

Table 2. Portal subsystem credentials and secrets

Secret or credential name	Description
`encryption-secret`	A 128-bytes long encryption secret that is used to do field level encryption in the portal subsystem database.
`original-encryption-secret`	A copy of the encryption-secret that was first used to generate the Kubernetes secret name. Do not modify this secret.
`site-backup-auth-ssh-key`	Authentication key for your remote portal backup SFTP server.

Advanced configuration for management subsystem

Specify advanced configuration for the management subsystem.

Note: VMware deployments include subsystem settings that cannot be reconfigured without a complete deployment. For example, for the Management Service these settings include hosts, endpoints, interfaces (`public-iface`, `traffic-iface`), IP ranges of the Kubernetes pod and the service networks (`k8s-pod-network`, `k8s-service-network`). Before reconfiguring, review the installation instructions for your subsystem to determine which settings are optional during initial installation and thus able to be updated later.
See:

- **Setting rate limits for public APIs on the management service**
  Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.
- **Configuring maximum size of client requests to the Management subsystem on VMware**
  You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.
- **Enabling API discovery on VMware**
  You can optionally configure API discovery in IBM® API Connect on VMware by enabling the API discovery service.
- **Enabling governance on VMware**
  You can optionally configure governance in IBM API Connect on VMware by enabling the governance service.

- **Configuring monetization on VMware**
  You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.
- **Enabling UI feature flags on VMware**
  Use a template override to update the installation CR with settings that control UI features.

Setting rate limits for public APIs on the management service

Describes the procedure for setting a rate limit for public APIs on the management service. Rate limits provide protection from DDoS (distributed denial of service) attacks.

Before you begin

These instructions assume you have the kubectl command-line tool installed. For more information, see https://kubernetes.io.

About this task

Rate limits can be set for public APIs on the management service. Rate limits on APIs help provide protection from DDoS (distributed denial of service) attacks. Without a rate limit, API calls from public APIs are unlimited.

The rate limit configuration requires that the header contains the actual client IP address. Any load balancer or proxy (for example, HAProxy) that is installed in front of the management service must be configured to pass the actual client IP address.

This procedure must be performed on a running API Connect deployment.

Rate limits are calculated as requests per seconds per client.

Note: If the rate limit has been reached on the management subsystem, the client will get an HTTP error: **`429 Too Many Requests`**.

Procedure

- Set a rate limit:
  1. Add the following entries to the extra-values-file:

     ```
     spec:
       template:
       - name: juhu
         containers:
         - name: juhu
           env:
           - name: RATE_LIMIT_PER_CLIENT
             value: "10"
           - name: LIMIT_REQUEST_OPTION
             value: "burst=10 nodelay"
     ```

     In this example, the first option sets the rate to 10 requests per second (10r/s). The second option allows 10 requests boosted without delay within < 1 second. You can customize as needed.

     The **`rateLimitPerClient`** property sets **`rate`**, and **`limitRequestOption`** sets **`[burst=number] [nodelay | delay=number]`** in the following nginx configuration:

     ```
     limit_req_zone key zone=name:size rate=rate;
     limit_req zone=name [burst=number] [nodelay | delay=number];
     ```

     Note that **`zone`** has been pre-defined and can't be configured. For more details, see the nginx doc http://nginx.org/en/docs/http/ngx_http_limit_req_module.html.

  2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
  3. Use **`apicup`** to update the VMware **`extra-values-file`** attribute to point to the new or updated management subsystem extra-values file:

     ```
     apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
     ```

     Where:
     - *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
     - *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

     For example:

     ```
     apicup subsys set ds10-management extra-values-file /workspace/v10012/my_extra_values.yaml
     ```

  4. Verify that the configuration settings are valid in the apiconect-up-v10.yaml by running the following command:

     ```
     apicup subsys get <mgmt_subsystem_name> --validate
     ```

     The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
  5. Run **`apicup`** to update the settings in the deployed Management subsystem.

     ```
     apicup subsys install <management-subsystem>
     ```

  6. Enter the following command to connect to the management subsystem using SSH:

     ```
     ssh ip_address -l apicadm
     ```

     You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

7. Select Yes to continue connecting, and once connected:

   ```
   sudo -i
   ```

8. Validate that the juhu pod has restarted by listing the pods:

   ```
   kubectl get pods  grep juhu
   ```

9. Check the AGE column to ensure a new juhu pod has started.
10. If the older juhu pod is still running, delete it with the following command:

    ```
    kubectl delete pods <old-juhu-pod>
    ```

- Disable a rate limit:
  1. Remove the values from the extra-values-file.
  2. Run `apicup` to update the settings in the deployed Management subsystem.

     ```
     apicup subsys install <management-subsystem>
     ```

  3. Enter the following command to connect to the management subsystem using SSH:

     ```
     ssh ip_address -l apicadm
     ```

     You are logging in with the default ID of *apicadm*, which is the API Connect ID that has administrator privileges.

  4. Select Yes to continue connecting, and once connected:

     ```
     sudo -i
     ```

  5. Validate that the juhu pod has restarted by listing the pods:

     ```
     kubectl get pods  grep juhu
     ```

  6. Check the AGE column to ensure a new juhu pod has started.
  7. If the older juhu pod is still running, delete it with the following command:

     ```
     kubectl delete pods <old-juhu-pod>
     ```

Configuring maximum size of client requests to the Management subsystem on VMware

You can configure the maximum allowed size of the client request body for requests made to the Management subsystem.

About this task

The default maximum size is 8 megabytes. You can increase this value.

Increasing the setting can be useful if you get errors when using the CLI to import a large API. Example error:

```
HTTP/1.1 413 Request Entity Too Large
```

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see Configuring maximum size of client requests to the Management subsystem.
- These instructions use an extra-values file. This file can be used to define CR overrides. Note that extra-values files for a CR can contain more than one override. If you already use an extra-values file, you can add the new override to it.
- All of the commands must be run in the `apicup` management project directory.

Procedure

1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

   ```
   spec:
     template:
     - name: juhu
       containers:
       - name: juhu
         env:
         - name: CLIENT_MAX_BODY_SIZE
           value: "12m"
   ```

2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
3. Use `apicup` to update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file:

   ```
   apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
   ```

   Where:
   - *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
   - *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

   For example:

   ```
   apicup subsys set ds10-management extra-values-file /workspace/v10011/my_extra_values.yaml
   ```

4. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

   ```
   apicup subsys get <mgmt_subsystem_name> --validate
   ```

   The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
5. Update the management VMware with the updated setting.

   ```
   apicup subsys install <mgmt_subsystem_name>
   ```

6. Monitor the health-check output until the management subsystem is healthy by running the following command:

   ```
   apicup subsys health-check <mgmt_subsystem_name>
   ```

   If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

   ```
   Error: Cluster not in good health:
    ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
    ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
   ```

   When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.

Enabling API discovery on VMware

You can optionally configure API discovery in IBM® API Connect on VMware by enabling the API discovery service.

About this task

The API discovery service is an optional add-on to API Connect that can be used to discover and add APIs to your API development process.

Note:

- These instructions apply only to VMware installations. For Kubernetes, OpenShift, and IBM Cloud Pak for Integration installations, see Enabling API discovery on Kubernetes.
- APIs cannot be discovered and added to your deployment until the API discovery service is enabled.
- All of the commands must be run in the `apicup` management project directory.
- If you're using a two data center disaster recovery (2DCDR) deployment, the API discovery service must be enabled on both the active and warm-standby centers. Enable the service on the warm-standby data center first, and then the active center.
- If you enable the API discovery service, the backups that you take can be restored only onto a management subsystem that also has the API discovery service enabled.

To enable or disable the API discovery service, see the following instructions:

- **Enabling the API discovery service**
- **Disabling the API discovery service**

After the API discovery service is enabled, API discovery resources can be created. For more information, see API discovery.

Procedure

- **Enabling the API discovery service**
  1. Open your API Connect installation project directory.
  2. Run the following `apicup` command to enable the API discovery service:

     ```
     apicup subsys set <mgmt_subsystem_name> api-discovery-enabled=true
     ```

     Where *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.

     Note: Optional: Run the following command to enable the proxy collector:

     ```
     apicup subsys set <mgmt-subsytem-name> api-discovery-gw-proxy-collector-enabled=true
     ```

  3. Install the new setting for the API discovery service by running the following command:

     ```
     apicup subsys install <mgmt_subsystem_name> --debug
     ```

     Including the `--debug` option enables the debug output for the command.

  4. Monitor the health-check output until the management subsystem is healthy by running the following command:

     ```
     apicup subsys health-check <mgmt_subsystem_name>
     ```

     If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

     ```
     Error: Cluster not in good health:
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
     ```

     When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
- **Disabling the API discovery service**
  1. Open your API Connect installation project directory.
  2. Run the following `apicup` command to disable the API discovery service:

```
apicup subsys set <mgmt_subsystem_name> api-discovery-enabled=false
```

Where **<mgmt_subsystem_name>** is the name of the management subsystem that you are configuring.

3. Install the new setting for the API discovery service by running the following command:

```
apicup subsys install <mgmt_subsystem_name> --debug
```

Including the **--debug** option enables the debug output for the command.

Results

Note that when the API discovery service is enabled, there are a number of new deployments, jobs, and pods in the **ManagementCluster** namespace. These Kubernetes API discovery resources have names that contain **api-discovery**. For example:

```
kubectl get pods -n apic | grep discovery
management-api-discovery-gw-proxy-collector-8d8bdfbdf51fbj   1/1     Running     0          88m
management-api-discovery-gw-proxy-collector-8d8bdfbdf67qqz   1/1     Running     0          88m
management-api-discovery-gw-proxy-collector-8d8bdfbdfzrhkv   1/1     Running     0          88m
management-api-discovery-service-f7dc497d8-gc7dn             1/1     Running     0          89m
management-api-discovery-service-f7dc497d8-pd877             1/1     Running     0          89m
management-api-discovery-service-f7dc497d8-shzm9             1/1     Running     0          89m
management-api-discovery-ui-5549df59d9-b4fks                 1/1     Running     0          88m
management-api-discovery-ui-5549df59d9-gjqmx                 1/1     Running     0          88m
management-api-discovery-ui-5549df59d9-pjvsx                 1/1     Running     0          88m
management-up-api-discovery-service-data-populate-0-tvxbvs   0/1     Completed   0          90m
management-up-api-discovery-service-schema-0-to-2-mrs8d      0/1     Completed   0          90m
```

Enabling governance on VMware

You can optionally configure governance in IBM® API Connect on VMware by enabling the governance service.

About this task

The governance service is an optional add-on to API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process.

Note:

- These instructions apply only to VMware installations. For Kubernetes, OpenShift, and IBM Cloud Pak for Integration installations, see Enabling governance on Kubernetes.
- Governance rulesets cannot be added to your deployment until the governance service is enabled.
- All of the commands must be run in the **apicup** management project directory.
- If you're using a two data center disaster recovery (2DCDR) deployment, the governance service must be enabled on both the active and warm-standby centers. Enable the service on the warm-standby data center first, and then the active center.

To enable or disable the governance service, see the following instructions:

- **Enabling the governance service**
- **Disabling the governance service**

After the governance service is enabled, governance resources can be created. For more information, see Configuring governance in the Cloud Manager, and Configuring governance in the API Manager.

Procedure

- **Enabling the governance service**
  1. Open your API Connect installation project directory.
  2. Run the following **apicup** command to enable the governance service:

     ```
     apicup subsys set <mgmt_subsystem_name> governance-enabled=true
     ```

     Where **<mgmt_subsystem_name>** is the name of the management subsystem that you are configuring.

  3. Install the new setting for the governance service by running the following command:

     ```
     apicup subsys install <mgmt_subsystem_name> --debug
     ```

     Including the **--debug** option enables the debug output for the command.

  4. Monitor the health-check output until the management subsystem is healthy by running the following command:

     ```
     apicup subsys health-check <mgmt_subsystem_name>
     ```

     If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of **1**. The following output is an example of unhealthy output while the install is running:

     ```
     Error: Cluster not in good health:
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
     ```

     When all of the health criteria are successfully met, the command displays no output, and exits with a status of **0**.
- **Disabling the governance service**

1. Open your API Connect installation project directory.
2. Run the following `apicup` command to disable the governance service:

   ```
   apicup subsys set <mgmt_subsystem_name> governance-enabled=false
   ```

   Where *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.

3. Install the new setting for the governance service by running the following command:

   ```
   apicup subsys install <mgmt_subsystem_name> --debug
   ```

   Including the `--debug` option enables the debug output for the command.

Results

Note that when the governance service is enabled, there are a number of new deployments, jobs, and pods in the `ManagementCluster` namespace. These Kubernetes governance resources have names containing either `compliance-service` or `compliance-ui`. For example:

```
kubectl get pods -n apic | grep compliance
management-compliance-service-f6cdf95fc-t4qkx                     1/1     Running     0          127m
management-compliance-ui-59897fcc4-zm25v                          1/1     Running     0          126m
management-up-compliance-service-data-populate-0-to-1-t2f4d       0/1     Completed   1          132m
management-up-compliance-service-schema-0-to-1-2lkqq              0/1     Completed   0
```

Configuring monetization on VMware

You can optionally configure monetization in API Connect on a VMware virtual machine by enabling the billing microservice.

Before you begin

Important: If the optional billing microservice is enabled, you must increase the memory for the API Manager for VMware component by 0.5 GB.

About this task

API Connect includes a subscription billing microservice that allows API providers to define pricing plans in their API Products, and monetize their API offerings. If a Product contains a pricing plan, API Consumers must enter their payment information into the Developer Portal before they can subscribe to that plan. API Connect supports integration with Stripe Subscription Billing, an independent cloud service that manages monetized product plans, customers, their payment information, and their subscription history, in order to generate monthly invoices and charge customers automatically. With this integration, Stripe serves as both the subscription billing system and the payment processing system.

Note:

- These instructions apply only to VMware installations. For Kubernetes installations, see Configuring monetization on Kubernetes.
- To use Stripe as your credit card processing vendor, you must have port 443 open to HTTPS communication between the Stripe API and your Developer Portal management and the Management cluster servers. See Firewall requirements and Firewall requirements on VMware for more information about this requirement.
- Provider organizations cannot add any billing integrations until the billing microservice is enabled.
- After provider organizations have added billing integrations, the billing microservice must not be disabled.
- All of the commands must be run in the `apicup` management project directory.

To enable or disable the billing microservice, you must configure a management subsystem extra-values file. See the following instructions:

- **Enabling the billing microservice**
- **Disabling the billing microservice**

Procedure

- **Enabling the billing microservice**
  1. Create, or edit if one already exists, a management subsystem extra-values file in the `apicup` management project directory, and enter the following configuration details:

     ```
     spec:
       billing:
         enabled: true
     ```

  2. Save the extra-values file with a filename of your choice, but it must have a .yaml or .yml extension.
  3. Update the VMware `extra-values-file` attribute to point to the new or updated management subsystem extra-values file.
     Run the following `apicup` command to insert the location of the extra-values file:

     ```
     apicup subsys set <mgmt_subsystem_name> extra-values-file <extra_values_file_path_and_name>
     ```

     Where:
     - *<mgmt_subsystem_name>* is the name of the management subsystem that you are configuring.
     - *<extra_values_file_path_and_name>* is the fully qualified path and name of your extra-values file.

     For example:

     ```
     apicup subsys set ds10-management extra-values-file /workspace/v10011/monetization.yaml
     ```

  4. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

     ```
     apicup subsys get <mgmt_subsystem_name> --validate
     ```

The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.

5. Update the management VMware with the updated billing value.
   Install the new setting for the billing microservice by running the following command:

   ```
   apicup subsys install <mgmt_subsystem_name> --debug
   ```

   Including the `--debug` option enables the debug output for the command.
6. Monitor the health-check output until the management subsystem is healthy by running the following command:

   ```
   apicup subsys health-check <mgmt_subsystem_name>
   ```

   If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

   ```
   Error: Cluster not in good health:
    ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
    ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
   ```

   When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
   The billing microservice is now enabled, and provider organization owners can create billing integration resources for API providers in the API Manager UI. For more information, see Monetizing your Products.

- **Disabling the billing microservice**
  Important: After provider organizations have added billing integrations, the billing microservice must not be disabled.
  1. Edit the management subsystem extra-values file in the `apicup` management project directory, and change the `enabled` configuration option to `false`:

     ```
     spec:
       billing:
         enabled: false
     ```

  2. Save the changed extra-values file.
  3. Verify that the configuration settings are valid in the apiconect-up.yaml by running the following command:

     ```
     apicup subsys get <mgmt_subsystem_name> --validate
     ```

     The output lists each setting and adds a check mark after the value once the value is validated. If the setting lacks a check mark and indicates an invalid value, reconfigure the setting.
  4. Update the management VMware with the altered billing value.
     Install the updated setting for the billing microservice by running the following command:

     ```
     apicup subsys install <mgmt_subsystem_name> --debug
     ```

     Including the `--debug` option enables the debug output for the command.
  5. Monitor the health-check output until the management subsystem is healthy by running the following command:

     ```
     apicup subsys health-check <mgmt_subsystem_name>
     ```

     If one or more of the health criteria are not met, the command stops processing and displays a message with the failure, and exits with a status of `1`. The following output is an example of unhealthy output while the install is running:

     ```
     Error: Cluster not in good health:
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
      ManagementCluster (current ha mode: active) is not ready | State: 15/17 Phase: Pending
     ```

     When all of the health criteria are successfully met, the command displays no output, and exits with a status of `0`.
     The billing microservice is now disabled.

Enabling UI feature flags on VMware

Use a template override to update the installation CR with settings that control UI features.

About this task

You can add a template override to the Management subsystem CR and use it to control whether specific features are available in the UI. Some features can be optionally disabled by users (by disabling them in the browser) provided you have enabled the feature for the cluster as a whole. Table 1 describes the available feature flags.

Table 1. Flags and settings for controlling UI features

Feature ID	Default Value	Partial Override For	Description
`ffAdvancedPublish`	`true`		Enable advanced publish option (deprecated)
`allOmniSearch`	`true`		Enables OmniSearch for all lists. This flag is used in conjunction with other flags.
`draftsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for drafts list
`catalogProductsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for catalog
`orgsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for org lists
`appsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apps

Feature ID	Default Value	Partial Override For	Description
`subscriptionsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for subscriptions, if disabled, subscription lists will be removed from catalog list
`requestedApprovalsOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for requested approvals
`approvalTasksOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for approvals
`productApisOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for apis within products
`membersOmniSearch`	`true`	`allOmniSearch`	Enable OmniSearch for member lists

Procedure

1. Add the template override to the `management-extra-values.yaml` file.
2. In the file, append the feature-flag definition to the end of the `spec:` section, making sure to adhere to the spacing used in the file.
   The following example enables the OmniSearch feature on all possible UI pages.

```
spec:
  template:
    - name: ui
      containers:
      - name: ui
        env:
          - name: APIC_UI_FEATURES
            value: allOmniSearch=always
```

   `APIC_UI_FEATURES` is a URL-encoded string. Each parameter is formed as `featureId=$featureValue`, and you can list multiple parameters with the `&` delimiter (`featureId=$featureValue&featureId=$featureValue`).

   Use the `featureId` values from Table 1. For each feature, specify one of the following `featureValue` settings:

   - `true` - On by default, but can be overridden by the user, for their browser alone
   - `false` - Off by default, but can be overridden by the user, for their browser alone
   - `never` - Off regardless of browser setting, disabled in feature flag page
   - `always` - On regardless of browser setting, disabled in feature flag page
3. Save the file.
4. Run the following command to update the deployment:

```
apicup subsys set <management_subsystem> extra-values-file <path_to_management-extra-values.yaml_file>
```

   The cluster is updated to enable or disable features as specified.

Configuring rate limits on the gateway nodes on VMware

Create an env.yaml file on each Gateway node to configure the default rate limit.

The Gateway uses scale limits (instead of strict limits) by default to enforce rate limits. This improves the gateway's performance by providing the ability to handle large amounts of rate-limited traffic.

1. To configure the rate limit, create a file called env.yaml with the settings provided in Table 1:

Table 1. Rate limit settings

Setting	Type	Default	Optoins	Comments
`USE_RATE_LIMIT_DEFINITION`	boolean	`true`	• `true` Use scale limits • `false` Use strict limits	Determines the type of rate limiting to use on the Gateway node.
`RATE_LIMIT_UPDATE_MODE`	enumerated	`prior`	• `none`No limits in a plan are incremented after a limit is reached. • `all` All limits in a plan are incremented after a limit is reached. • `prior` Retains the behavior from pre-V10 releases: When the plan rate limit is reached, all limits in the plan that are sorted before that plan limit will be incremented.	Determines how the counts within a plan are incremented when a rate limit is hit. Applies only to scale limits.

Setting	Type	Default	Optoins	Comments
`RATE_LIMIT_SORT_BY_DURATION`	boolean	`true`	• `true` Sort the rate limits by duration. • `false` Revert to the previous sort order.	Determines the sort order for rate limits in a plan, which in turn determines the sequence in which they are applied.
`RATE_LIMIT_USE_OFFSET`	boolean	`false`	• `true` Prevent all rate limit counts for an interval from being reset at the same time. • `false` Allow all rate limit counts for an interval to be reset at the same time.	Allow or prevent all of the rate limit counts for an interval from being reset at the same time. Preventing the simultaneous reset protects backends from being saturated with requests by resetting the counts for different subscribers of a plan at different points with in the interval. Applies only to scale limits.
`RATE_LIMIT_DEFINITION_RESPONSE_HEADERS`	boolean	`true`	• `true` Show the `x-rate-limit` headers. • `false` Hide the `x-rate-limit` headers.	Show or hide the `x-rate-limit` headers in an API response. Applies only to scale limits.

2. Save the file in the local:/ directory on the Gateway node so that the file persists on reboots of both physical and virtual machines. The settings apply only to the node where the file is stored, so each node in the Gateway cluster requires its own copy of the file.

Backing up and restoring on VMware

Backup and restore API Connect on VMware.

Note: Backups are for recovery of the API Connect subsystems in the same VMware environment where the backups were taken.
If you want to restore API Connect subsystem backups in a different VMware environment, be aware of the following points:

- Every API Connect network endpoint that was defined with **apicup** and all URLs specified in the API Connect UIs must resolve correctly in the new environment. For example, if you configured your platform API endpoint as `platform.myapiconnect.com`, that endpoint must be valid in your new environment.

  It is only possible to change endpoints for an API Connect deployment by following the form factor migration procedure.

- If you did not use the original VM hostnames or IP addresses in your API Connect endpoints, then you can deploy your new VMs with different hostnames and IP addresses.

A complete API Connect VMware deployment backup consists of the following items:

- Project directory backup.
  The original project directory that was created with the `apicup` command during the initial product installation is essential for disaster recovery.
- Management certificates backup.
  Backup your management subsystem certificates by using the `dr-preparation` script.
- Subsystem database backups.
  Your management, portal, and analytics subsystems all have databases that contain your API Connect configuration, which includes:
  - Everything that you create and configure in the Cloud Manager and API Manager UI (APIs, products, TLS profiles, user registries, and so on), or with the toolkit CLI or REST API.
  - Your developer portal sites and customizations made.
  - Your analytics data.

  Subsystem database backups can be configured to run automatically following a `cron` schedule.

Note: For information about how to maintain a two data center deployment, including backup and restore considerations, see Maintaining a two data center deployment.

- **Project directory backup**
  Backup your project directory so that your API Connect subsystems can be recovered after a disaster.
- **Backing up and restoring the management subsystem**
  How to backup your management subsystem, configure scheduled database backups, and restore your management subsystem on VMware.
- **Backing up and restoring the portal subsystem**
  How to backup your portal subsystem, configure scheduled database backups, and restore your portal subsystem on VMware.
- **Backing up and restoring the analytics subsystem**
  Backup your analytics subsystem project directory and configure scheduled database backups. The analytics database can be backed up to a remote SFTP server or object-store.
- **Using VM snapshots for infrastructure backup and disaster recovery**
  You can use VM snapshots to backup and restore API Connect on VMware, and also for infrastructure disaster recovery.
- **Disaster recovery**
  Recover your API Connect deployment after a disaster event.

Project directory backup

Backup your project directory so that your API Connect subsystems can be recovered after a disaster.

The original project directory that was created with the **apicup** command during the initial product installation is essential for disaster recovery, see: Preparing to install API Connect in VMware. The project directory contains the YAML files that describe your deployment, encryption keys, and deployment ISO files. It is not possible to restore your subsystem database backups on a deployment that uses a new or different project directory.

Take a new backup of your project directory every time you make any configuration changes with the **apicup** command. Store your project directory backup at a remote location.

Ensure that you keep all files related to your API Connect subsystems in the project directory, so they are included in your project directory backup. For example:

- Any TLS certificate files that were used to customize subsystem certificates.
- YAML files used to customize subsystems.
- Your management extra-values.yaml file, if you created one, for example: Configuring maximum size of client requests to the Management subsystem on VMware.
- Your portal **ptl-extra-values.yaml** file, if you created one.
- Your Analytics extra-values file if you created one.

Whenever you update your API Connect deployment with the **apicup** command, take a new backup of the project directory.

Backing up and restoring the management subsystem

How to backup your management subsystem, configure scheduled database backups, and restore your management subsystem on VMware.

Management subsystem backups are intended for restoration in the same VMware environment where they were taken, or a different VMware environment that has the same network configuration, endpoints, and deployment profile.

A management subsystem backup consists of:

- Project directory backup.
  The original project directory that was created with the **apicup** command during the initial product installation is essential for disaster recovery, see: Preparing to install API Connect in VMware.
- Management certificates backup.
  Backup your management subsystem certificates by using the **dr-preparation** script.
- Management database backup.
  Your management database backup contains everything that you create and configure in the Cloud Manager and API Manager UI (APIs, products, TLS profiles, user registries, and so on), or with the toolkit CLI or REST API. You configure your management subsystem to run scheduled database backups. You can also take database backups on-demand.

  You configure your database backups with **apicup** commands ran from your project directory. Therefore, to restore the management database backup after a disaster, you must first restore your project directory.

VMware snapshots

Take a Virtual Machine (VM) snapshot of all your management VMs; see Using VM snapshots for infrastructure backup and disaster recovery. Taking snapshots does require a brief outage while all the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can provide faster recovery when compared to redeploying VMs and restoring from a database backup.

Important: VM snapshots are not an alternative to taking API Connect project directory, certificate, and database backups. Do not rely solely on VM snapshots for your backups.

- **Backing up your management certificates**
  How to backup your management subsystem certificates on VMware.
- **Configuring management database backups**
  Configure your management subsystem to take regular scheduled database backups, and enable on-demand database backups.
- **Running an on-demand backup of the management database**
  Create a management database backup at any time, by running an **apicup** command.
- **Restoring from a management database backup**
  Use the **apicup** command to list backups and then restore the selected backup of the management database.
- **Management subsystem disaster recovery**
  Recover the management subsystem in a VMware environment.

Backing up your management certificates

How to backup your management subsystem certificates on VMware.

Backup your management subsystem certificates by using the **dr-preparation** script.

1. Download **v10_ova_dr_files-<*version*>.tgz** from IBM Fix Central.
2. Decompress **v10_ova_dr_files-<*version*>.tgz** to extract the dr-preparation-py script:

   ```
   tar -xzf v10_ova_dr_files-<version>.tgz
   ```

3. Copy the v10-dr/dist/dr-preparation-py script to one of your management VMs:

   ```
   scp v10-dr/dist/dr-preparation-py apicadm@<management vm>:/home/apicadm
   ```

   Note: On three replica deployments, you can run this script on any of the management VMs.

4. Log in to the management VM:

   ```
   ssh apicadm@<management vm>
   ```

5. Run the dr-preparation-py script:

   ```
   sudo python3 dr-preparation
   ```

   The script creates the output file apicup-commands.txt that contains the **apicup** commands. The **apicup** commands that are generated include the encoded certificates of your management subsystem. In a disaster recovery scenario, you redeploy your management subsystems and run these **apicup** commands to re-create the certificates.

   Verify that the file contains the following **apicup** commands:

   ```
   apicup certs set management atm-credential --encoded-string '<encoded_string>'
   apicup certs set management consumer-toolkit-credential --encoded-string '<encoded_string>'
   apicup certs set management designer-credential --encoded-string '<encoded_string>'
   apicup certs set management toolkit-credential --encoded-string '<encoded_string>'
   apicup certs set management juhu-credential --encoded-string '<encoded_string>'
   apicup certs set management consumer-ui-credential --encoded-string '<encoded_string>'
   apicup certs set management ui-credential --encoded-string '<encoded_string>'
   apicup certs set management encryption-secret --encoded-string '<encoded_string>'
   apicup certs set management discovery-credential --encoded-string '<encoded_string>'
   apicup certs set management governance-credential --encoded-string '<encoded_string>'
   apicup subsys set management site-name='<site_name>'
   ```

   Note: If any of the certificates are missing, the script shows an error message. Resolve any errors before you continue, or you cannot successfully recover from a disaster event.
6. Copy the apicup-commands.txt file off the VM and store it with your project directory backup.

Configuring management database backups

Configure your management subsystem to take regular scheduled database backups, and enable on-demand database backups.

About this task

- You use the `apicup` command to configure database backup settings for the management subsystem.
- Database backups can be scheduled or generated manually (on-demand).
- You must backup both the management and portal databases at the same time to ensure synchronicity across the services.
- You must have a remote SFTP server or S3-compatible object-store available to store your management database backups. OpenSSH key authentication for SFTP is supported.

  Types of object-stores supported:
  - IBM Cloud Object Storage.
  - AWS S3.
  - Any custom S3, such as minIO.

- The public certificate on the object-store provider must be signed by a known certificate authority that your management subsystem trusts. Use of an untrusted authority can cause the following error during backup upload: `x509: certificate signed by unknown authority`.
- Restoring a database backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For information about the registration credentials, see Changing the registration client_id and client_secret for applications.
- You can modify any of the backup settings at any time, but if you change the `database-backup-auth-user` or `database-backup-auth-pass` settings, you must run:

  ```
  apicup subsys db-reload <subsystem_name>
  ```

  after the new settings are applied with:

  ```
  apicup subsys install <subsystem_name>
  ```

Important: A management database backup alone cannot be used for disaster recovery. Ensure that you also always have an up to date Project directory backup.

Procedure

1. Use `apicup` to specify backup settings:

   ```
   apicup subsys set <subsystem_name> <setting>=<value>
   ```

Table 1. Configuration settings for management subsystem database backup

Parameter	Description

Parameter	Description
database-backup-auth-pass	The password or access key for the SFTP server or object-store that you specified in **database-backup-host**. The password is converted and stored in Base64 encoded format. For example: **apicup subsys set *<subsystem_name>* database-backup-auth-pass '*<password>*'** Note: You cannot use the `=` sign to assign the password to **database-backup-auth-pass**. If you change this value later, to apply the change you must run **apicup subsys db-reload *<subsystem_name>*** after you run: **apicup subsys install *<subsystem_name>***
database-backup-auth-ssh-key	Applies to SFTP only. OpenSSH private key. Changing this value restarts the management database. Important: • Use **apicup certs** to set this value. Do not use **apicup subsys**. • Only OpenSSH keys are supported.[1] **apicup certs set *<subsystem_name>* database-backup-auth-ssh-key *<ssh private key filepath>***
database-backup-auth-user	The username or secret key ID for the host that you specify in **database-backup-host**. **apicup subsys set *<subsystem_name>* database-backup-auth-user *<username>*** If you change this value later, to apply the change you must run **apicup subsys db-reload *<subsystem_name>*** after you run: **apicup subsys install *<subsystem_name>***
database-backup-host	Not required if **database-backup-protocol=local**. Specify your SFTP server hostname or object-store endpoint with the corresponding object-store region in the format **<S3endpoint>/<S3region>**. Examples: • **apicup subsys set *<subsystem_name>* database-backup-host=sftp.example.com** • **apicup subsys set *<subsystem_name>* database-backup-host=s3.ibm.com/eu-west-2** • **apicup subsys set *<subsystem_name>* database-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud/eu-standard**
database-backup-path	Not required if **database-backup-protocol=local**. The path to the location of the backup. • SFTP: The absolute path of the folder on the SFTP server, beginning with /. **apicup subsys set mgmt database-backup-path=*<full path to backups directory>*** • Object-store: The bucket on your object-store, in the format **bucket-name/folder**. The use of subdirectories in the bucket name is not supported. Ensure that the bucket is empty. When your deployment includes a management subsystem in two different clusters (with active databases), the two management subsystems cannot use the same object-store bucket name in the database backup configurations. Each management subsystem must use a unique object-store bucket name. **apicup subsys set *<subsystem_name>* database-backup-path=*<bucket-name/folder>***
database-backup-port	Applies to SFTP only. The port for the protocol to connect to the **database-backup-host**. The default value is 22. **apicup subsys set mgmt database-backup-port=*<port_number>***
database-backup-protocol	Set to **objstore**, **sftp**, or **local**. Default is **local**. **apicup subsys set *<subsystem_name>* database-backup-protocol=*<protocol>***

Parameter	Description

`database-backup-schedule`	Cron schedule for when database backups are run. The format for the schedule is:
	
	`* * * * * *`
	`- - - - - -`
	`| | | | | |`
	`| | | | | +----- day of week (0 - 6) (Sunday=0)`
	`| | | | +------- month (1 - 12)`
	`| | | +---------- day of month (1 - 31)`
	`| | +------------ hour (0 - 23)`
	`| +-------------- min (0 - 59)`
	`+---------------- sec (0 - 59)`
	
	The default is an empty string, which means no backups are taken.
	
	The time zone for backups is UTC.
	
	This example schedules a backup to run daily at 01:00:
	
	`apicup subsys set <subsystem_name> database-backup-schedule="0 0 1 * * *"`

`database-backup-certs`	Applies to object-store only.
	
	If your object-store has a custom CA certificate, then you must configure your management subsystem to trust this certificate.
	
	a. Log in to one of your management VMs:
	
	`ssh apicadm@<management hostname>`
	
	b. Switch to the `root` user:
	
	`sudo -i`
	
	c. Follow the steps for creating a Kubernetes secret that contains your object-store's CA certificate, as described for Kubernetes platforms in step 2 on Configuring management database backups. Use `default` for the *<namespace>* variable.
	
	d. Exit from the VM, and use **apicup** to set `database-backup-certs` to the Kubernetes secret that you created:
	
	`apicup subsys set <subsystem_name> database-backup-certs=mgmt-custom-objstore-ca`

`database-backup-s3-uri-style`	Applies to object-store only. **Optional**: Specifies whether the URI is in the form of `host` or `path`. `apicup subsys set <subsystem_name> database-backup-s3-uri-style='<host|path>'` Supported values: • `host` • `path`
`database-backup-repo-retention-full`	The number of days of backups to retain. For example, if `database-backup-repo-retention-full` is set to 30, then backups for the last 30 days are retained. Older backups are deleted. After a restore, the count of the number of days is reset to zero. Minimum value: 1 Maximum value: 9999999 Default: none

2. Confirm that the backup settings pass validation:
   - To view all subsystem settings except `database-backup-auth-ssh-key`:

     `apicup subsys get <subsystem name> --validate`

   - To view `database-backup-auth-ssh-key`:

     `apicup certs get <subsystem name> database-backup-auth-ssh-key --type key`

   If you are configuring the backup settings before installation, then skip the remaining steps and continue with the installation process. Verify that your backups are working after installation.

3. Apply the settings:

   `apicup subsys install <subsystem name>`

4. Ensure that the changes were applied successfully:

   `apicup subsys health-check <subsystem name>`

5. Take a new backup of your project directory.
   Your backup configuration settings are stored in your project directory. Take a new backup of your project directory every time you update your backup settings or make any other configuration updates with the **apicup** command.

6. Verify that your backup settings are correct by running an on-demand backup: Running an on-demand backup of the management database.

Running an on-demand backup of the management database

Create a management database backup at any time, by running an **apicup** command.

Before you begin

- Database backup settings for the management subsystem must be configured. See Configuring management database backups.
- Take a backup of the portal database at the same time as you take a backup of the management database. The portal and management databases must remain consistent with each other.
- Do not attempt to run more than one management database backup at a time. Check that no backups are running:

  ```
  apicup subsys list-backups <management subsystem name>
  ```

  Check that the scheduled backup is not configured to run before you expect your on-demand backup to finish:
  - For Linux

    ```
    apicup subsys get <management subsystem name> |grep database-backup-schedule
    ```

  - For Windows

    ```
    apicup subsys get <management subsystem name> | findstr database-backup-schedule
    ```

Procedure

1. Check that your management subsystem is healthy:

   ```
   apicup subsys health-check <management subsystem name>
   ```

   When successful, the command returns silently with an exit code of `0`.

2. Use the **apicup** command to start the backup process:

   ```
   apicup subsys backup <management subsystem name>
   ```

3. Monitor the backup process with:

   ```
   apicup subsys list-backups <management subsystem name>
   ```

   Example output:

   ```
   NAME                                AGE     CLUSTER                 METHOD                PHASE       ERROR
   mgmt-backup-rnvx8                   15m     stv3-management-site1-db   ObjectStore   completed
   stv3-management-20240617010000   7h46m   stv3-management-site1-db   ObjectStore   completed
   ```

   For more information about the backup, use the `detailed-output` flag:

   ```
   apicup subsys list-backups <management subsystem name> --detailed-output=true
   ```

Restoring from a management database backup

Use the `apicup` command to list backups and then restore the selected backup of the management database.

Before you begin

- If you restore the management subsystem database, you must also restore the portal subsystem database from a backup that was taken at the same time. The database backups of the management and portal must be taken at the same time to ensure that the portal sites are consistent with the management database.
- Restoring the management database requires downtime and is a destructive process that deletes current data and copies backup data. During the restoration process, external traffic must be stopped.
- To restore the management database, you must use the original project directory that was created with `apicup` during the initial product installation. You cannot restore the database without the initial project directory. If necessary, restore the project directory from your Project directory backup.

About this task

Restoring a backup restores the registration credentials (client_ID, client_secret) that were in use at the time that the selected backup was created. For more information about the registration credentials, see Changing the registration client_id and client_secret for applications.

Procedure

1. List the available backups:

   ```
   apicup subsys list-backups <management subsystem name>
   ```

   Example output:

   ```
   NAME                                AGE     CLUSTER                 METHOD                PHASE       ERROR
   mgmt-backup-rnvx8                   15m     stv3-management-site1-db   ObjectStore   completed
   stv3-management-20240617010000   7h46m   stv3-management-site1-db   ObjectStore   completed
   ```

   Take note of the name of the backup that you want to restore.
   If the backup you want to restore is not listed, but you know where it is on your SFTP server or object-store, then you can restore by using the backup ID instead of the backup name, seeRestore with ID.

2. Restore the backup.
   Two methods are available to restore a backup:
   - Restore with the backup name identified in step 1.

```
apicup subsys restore <management subsystem name> --name <backupname> <flags>
```

Available flags:

```
apicup subsys restore mgmt --help
Restore management subsystem

Usage:
  restore SUBSYS [flags]

Flags:
      --backup-certs string      Backup certs which are used for TLS communication between APIC and backup server.
Currently only supported for objstore backups.
      --debug                    Enable debug logging
  -h, --help                     help for restore
      --host <host>/<myregion>   FQDN for DB backups server in format <host>/<myregion>
      --id string                ID of the backup to restore
      --name string              Name of the backup to restore
      --password string          Password for DB backups server
      --path string              Path for DB backups server
      --port int                 Server port for DB backups (default 22)
      --protocol string          Protocol for DB backups server ('objstore', 'sftp', 'local')
      --s3-uri-style string      Supports either 'host' or 'path'. Supported only for 'objstore' backups.
      --ssh-key string           OpenSSH private key file path for DB backups using SFTP only
      --username string          Username for DB backups server
      --wait                     Wait for the operation to complete or fail.
      --wait-timeout duration    Command timeout in seconds. (default 40s)
```

Example:

```
apicup subsys restore boaz-ova2-management --name mgmt-backup-qdbfn

Starting restore...
please check later for completion status of restore
ManagementRestore is RestoreInProgress
```

- Restore with the backup ID.
  If you do not have a backup name for the backup you want to restore, you can use a backup ID. Look on your SFTP server or object-store to identify the ID of the management database backup that you want to restore.

  Management database backups appear as folders that use a datestamp for their name, and are located inside the backup path. Example of a management database backup with its full path:

  ```
  apic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z/base/20230914T013040
  ```

  - `apic-mgmt-backups/impr-restore/m1-65288d1d-db-2023-09-14T01:30:40Z` is the backup path. The datestamp `2023-09-14T01:30:40Z` indicates when the management database was created (not when the backup was created). The management database is created on initial installation, and re-created when a backup restore is run. The path with the most recent datestamp should contain the most recent backups.
  - `20230914T013040` is the backup ID. The format indicates the date and time that the backup was taken.

  When you restore with a backup ID, you must include the SFTP server or object-store host, path, protocol, username, and password as flags in the restore command:

  ```
  apicup subsys restore <management subsystem name> --id <backup ID> --host <hostname> --protocol <protocol>--username
  <username> --password <password> --path <backup path>
  ```

  For example:

  ```
  apicup subsys restore boaz-ova2-management --id 20230725T162548 --host s3.eu-gb.cloud-object-
  storage.appdomain.cloud/eu-gb --username 'a05e7aace2ab43b5941326429c8c071c' --password
  '3e510a1d9b06189b57334d064badf6abc39ab5a51d9bdcf7' --path upgrade-test/boaz-ova1-management-22/management-site1-db-
  2023-11-16T12:30:02Z

  Starting restore...
  INFO[0000] Creating generic secret mgmt-restore-auth-secret.
  please check later for completion status of restore
  ManagementRestore is RestoreInProgress
  root@apicdev3067:/home/apicadm/boaz-ova2# k get mgmtr
  NAME                  STATUS              MESSAGE
  BACKUP               CLUSTER               PITR                  AGE
  NAME                  STATUS     MESSAGE                                                  BACKUP              CLUSTER
  PITR                  AGE
  mgmt-restore-t6ss5    Complete   Restore process completed (DB Restore + DRR job)   mgmt-backup-cdkv6   boaz-ova2-
  management   2023-07-25T16:25:58   127m
  mgmt-restore-tgxl2    Complete   Restore process completed (DB Restore + DRR job)                       boaz-ova2-
  management
  ```

3. Monitor the restore:

   ```
   apicup subsys list-restores <management subsystem name>
   ```

   The `list-restores` command shows `RestoreSuccessful` when the restore is complete.

What to do next

Restore your portal database backup: Restoring the portal database backup.

Management subsystem disaster recovery

Recover the management subsystem in a VMware environment.

About this task

Recovering the management subsystem involves re-creating your management ISO files, redeploying your management VMs with the new ISO files, and then restoring the management database from your backup.

Important points:

- In a three replica deployment, if any one VM is corrupted then all the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.
- When you restore the management subsystem database, you must then restore the portal subsystem database from a backup that was taken at the same time. The database backups of the management and portal must be taken at the same time to ensure that the portal sites are consistent with management database.
- The disaster recovery process is intended for restoration of API Connect in the same VMware environment with the same endpoints.
  If you want to restore in a different VMware environment, all configured API Connect endpoints must be valid in the new environment. If the original host name or IP address was not used in any of your API Connect endpoints, then you can give your VMs a different hostname and IP address.

  If you want to change API Connect endpoints or migrate to a different form-factor, see Migrating from v10 to v10 on a different form factor.

Procedure

1. Use the same project directory that you used for your original deployment, or a restore of your Project directory backup.
2. Create your ISO files:

   ```
   apicup subsys install <subsystem name> --out <output directory>
   ```

   where *<output directory>* is the directory where the ISO files are to be created.
   Note: If your original ISO files are still available and you did not upgrade from the original installation, you can reuse them. However, if you upgraded your original deployment, you must create new ISO files using the version of **apicup** that corresponds to the version your API Connect installation was on at the time of the disaster. For example, do not attempt to deploy v10.0.8.x OVAs with ISO files that were created with **apicup** v10.0.6.0.
   If you are restoring in a different VMware environment, you can change the hostname, IP address, and other properties that you set with `apicup iface create` before you create the ISO files. Use `apicup iface create` to define your new network interface, and then `apicup iface delete` to delete the original one. Do not update any other settings with `apicup`, and if your original VM hostname was used in any of your API Connect endpoints, then you cannot change the hostname.
3. Deploy your new management VMs: Deploying the management subsystem OVA.
4. Restore the management subsystem certificates with the **apicup** commands that you generated in Backing up your management certificates.
   Run the **apicup** from the apicup-commands.txt file:

   ```
   apicup certs set management atm-credential --encoded-string '<encoded_string>'
   apicup certs set management consumer-toolkit-credential --encoded-string '<encoded_string>'
   apicup certs set management designer-credential --encoded-string '<encoded_string>'
   apicup certs set management toolkit-credential --encoded-string '<encoded_string>'
   apicup certs set management juhu-credential --encoded-string '<encoded_string>'
   apicup certs set management consumer-ui-credential --encoded-string '<encoded_string>'
   apicup certs set management ui-credential --encoded-string '<encoded_string>'
   apicup certs set management encryption-secret --encoded-string '<encoded_string>'
   apicup certs set management discovery-credential --encoded-string '<encoded_string>'
   apicup certs set management governance-credential --encoded-string '<encoded_string>'
   apicup subsys set management site-name='<site_name>'
   ```

5. Verify your new management deployment, but do not log in to the Cloud Manager UI or attempt to configure or change any other settings: Verifying the management subsystem installation.
6. Restore your management database backup, using backup ID.

Backing up and restoring the portal subsystem
