How to backup your portal subsystem, configure scheduled database backups, and restore your portal subsystem on VMware.

A portal subsystem backup consists of the following items:

- Project directory backup
  The original project directory that was created with the `apicup` command during the initial product installation is essential for disaster recovery, see: Preparing to install API Connect in VMware.
- Portal database backup.

It is recommended that you configure the portal database backup settings during installation. If you did not do so when you installed API Connect in your runtime environment, you must configure the database backups for the portal before you can upgrade.

Important:

- You must backup both the management and portal databases at the same time to ensure synchronicity across the services.
- When restoring, the management, analytics, and developer portal subsystems must be at the same version and fix pack level.

Snapshots

Take a Virtual Machine (VM) snapshot of all your portal VMs; see Using VM snapshots for infrastructure backup and disaster recovery. Taking snapshots does require a brief outage while all the VMs in the subsystem cluster are shut down - do not take snapshots of running VMs, as they might not restore successfully. VM snapshots can provide faster recovery when compared to redeploying OVAs and restoring from a database backup.

Important: VM snapshots are not an alternative to the standard API Connect backups that are described in this section. Do not rely solely on VM snapshots for your backups.

- **Configuring portal database backups**
  Use the `apicup` command to configure scheduled portal database backups on VMware.
- **Running an on-demand backup of the portal database**
  When your portal database backup settings are configured, you can use `apicup` to create an on-demand backup of the portal database.
- **Restoring the portal database backup**
  Use the `apicup` command to restore the portal subsystem database.
- **Portal subsystem disaster recovery**
  Recover the portal subsystem on VMware.

Configuring portal database backups

Use the `apicup` command to configure scheduled portal database backups on VMware.

About this task

You can configure portal database backup settings before installation (before you create the portal ISO file), or after installation.

You can update the portal database backup settings at any time.

- Supported remote storage for portal database backups:
  - IBM Cloud Object Storage
  - AWS S3
- SFTP. OpenSSH key authentication for SFTP is supported.

Important: A portal database backup alone cannot be used for disaster recovery. Ensure that you also always have a recent Project directory backup.

Procedure

1. From your API Connect project directory, run the following commands to set the remote backup location and schedule:

   ```
   apicup subsys set <subsystem name> <property>=<value>
   ```

   For example:

   ```
   apicup subsys set ptl site-backup-host=mybackuphost.com
   apicup subsys set ptl site-backup-port=22
   apicup subsys set ptl site-backup-auth-user=mybackupauthusername
   apicup subsys set ptl site-backup-auth-pass=mybackupauthpassword
   apicup subsys set ptl site-backup-path=/site-backups
   apicup subsys set ptl site-backup-protocol=sftp
   apicup subsys set ptl site-backup-certs=<custom-s3-server-CA-cert>
   apicup subsys set ptl site-backup-s3-uri-style=<host-or-path>
   apicup subsys set ptl site-backup-schedule="0 2 * * *"
   apicup subsys set ptl site-priority-list=portal.a1.example.com/test-1/spacecatalog,portal.a1.example.com/test-
   4/cat3,portal.a1.example.com/test-3/cat1
   apicup certs set <subsystem name> site-backup-auth-ssh-key <ssh-key-file-path>
   ```

   The backup parameters are detailed in the following table.

Table 1. Portal backup parameters

Parameter	Description

`site-backup-host`	The fully qualified domain name of the backup server, in lowercase only.
	• For `objstore` type backup, specify the S3 endpoint with the corresponding S3 region in the format `<S3endpoint>`, or with an optional S3 region in the format `<S3endpoint>/<S3region>`.
	`apicup subsys set ptl site-backup-host=s3.eu-gb.cloud-object-storage.appdomain.cloud`
	or
	`apicup subsys set ptl site-backup-host=s3.cloud-object-storage.appdomain.cloud/eu-gb`
	• For `sftp` type, the SFTP server hostname
	`apicup subsys set ptl site-backup-host=my.sftp.backup.domain.example.com`

`site-backup-port`	The port for the protocol to connect to the `site-backup-host`. Defaults to `22` if not explicitly set. The backup port is not required for object storage but if specified, is typically port 443. `apicup subsys set ptl site-backup-port=22`
`site-backup-auth-user`	The username for the host that is specified in `site-backup-host`. If you are using an object-store, the username is the S3 Secret Key ID. `apicup subsys set ptl site-backup-auth-user=<user name>`
`site-backup-auth-pass`	The password for the host that is specified in `site-backup-host`. If you are using an object-store, the password is the S3 Secret Access Key parameter. The password is stored in Base64 encoded format, and must not be edited directly in the apiconnect-up.yml file. `apicup subsys set ptl site-backup-auth-pass=password`

Parameter	Description
site-backup-auth-ssh-key	OpenSSH key for database backups by using SFTP. Important: • Use **apicup certs** to set this value. Do not use **apicup subsys**. • Only OpenSSH keys are supported.[1] **apicup certs set ptl site-backup-auth-ssh-key=<*ssh-key-file-path*>**
site-backup-path	The location of the backups on the remote host: • S3 - the name of your S3 bucket to store backup data, optionally followed by a **/** and then any subdirectories inside the bucket. Valid examples: **bucket** **bucket/path** **bucket/lots/of/paths** Example: **apicup subsys set ptl site-backup-path=apic-backup** • SFTP - the full absolute path of the folder on the SFTP server, beginning with **/**. **apicup subsys set ptl site-backup-path=<*/folder*>** When you specify a file path in a backup setting, be sure to escape any blank spaces in the path.
site-backup-protocol	The protocol that is used to communicate with your remote backup endpoint. Specify one of the following values: • **sftp** - for secure file transfer protocol • **local** - for local storage • **objstore** - for S3 compatible object storage Starting with v10.0.3.0, the default protocol is **local** (earlier releases used **sftp** as the default). For example: **apicup subsys set ptl site-backup-protocol=local**
site-backup-certs	The name of a custom certificate that contains your upstream custom object-store CA certificate. This field accepts the name of the Kubernetes secret that contains your upstream custom S3 CA certificate. The key of the secret must be **ca.crt** and the value is the base64-encoded value of the CA certificate. If the server certificate that your object-store presents is signed by a well-known CA and includes any intermediate certificates in the chain, then you do not need to provide the CA certificate. If you are not sure what CA certificate your object-store uses, then configure portal database backups without setting **site-backup-certs** and verify that backups work and no TLS errors are logged. If you do need to provide the CA certificate then you must provide the entire chain in the **ca.crt** member of the secret, as follows: **intermediate-certificate-1** **intermediate-certificate-2** **. . .** **intermediate-certificate-*n*** **root-certificate** Where the first certificate in the **ca.crt** member (intermediate-certificate-1) is the issuer of the object-store server certificate, and each subsequent certificate in the **ca.crt** member is the issuer of the preceding certificate. The root certificate in the **ca.crt** member must be self-signed. If there are no intermediate certificates, then the **ca.crt** member contains only the root certificate. Follow these steps to create and assign the CA certificate: a. Log in to your portal VM. If you have a three replica deployment, log in to any of the portal VMs. **ssh apicadm@<portal vm hostname>** b. Switch to the root user: **sudo -i** c. Copy over the **ca.crt** file or create it on the VM by creating a file of the same name and pasting in the contents. d. Create a Kubernetes secret from the **ca.crt** file: **kubectl create secret generic custom-portal-objstore-ca --from-file=ca.crt=/path/to/ca.crt** e. Take a backup of the generated Kubernetes secret: **kubectl get secret custom-portal-objstore-ca -o yaml > custom-portal-objstore-ca.yaml** Keep the generated custom-portal-objstore-ca.yaml file in your project directory. f. Exit from the VM, and set the **site-backup-certs** property to **custom-portal-objstore-ca**: **apicup subsys set ptl site-backup-certs=custom-portal-objstore-ca**

Parameter	Description
`site-backup-s3-uri-style`	Applies to object-store only. **site-backup-s3-uri-style** is an optional property. Indicates whether URIs to your object-store backup should use a host or a path value. When not specified, defaults to **host**. Valid values: **host** and **path**. Some custom object-store providers require the URI style to be set to **path**. For example, MinIO supports both **host** and **path** style setup. You can create a MinIO S3 server to accept only **path** style client communications. Important: Contact your object-store administrator before you set this property. If not properly configured, an object-store can reject connections from the client.

`site-backup-schedule`	The schedule for how often automatic portal backups are run. The format for the schedule is any valid cron string, as follows:
	
	`* * * * *`
	`- - - - -`
	`| | | | |`
	`| | | | +----- day of week (0 - 6) (Sunday=0)`
	`| | | +------- month (1 - 12)`
	`| | +--------- day of month (1 - 31)`
	`| +----------- hour (0 - 23)`
	`+------------- min (0 - 59)`
	
	For example: `30 22 * * 1` runs backups at 22:00 on Mondays.
	The default backup schedule is `0 2 * * *` (runs every day at 02:00).
	
	The time zone for backups is Coordinated Universal Time.
	
	`apicup subsys set ptl site-backup-schedule="0 2 * * *"`

`site-priority-list`	Optional list of prioritized sites to restore. Default: empty.
	
	`apicup subsys set <subsystem name> site-priority-list <comma-separated-list-of-sites>`
	
	For example:
	
	`apicup subsys set ptl site-priority-list portal.a1.example.com/e2etest-1/spacecatalog,portal.a1.example.com/e2etest-4/cat3,portal.a1.example.com/e2etest-3/cat1`

2. You can review your portal backup settings with the **apicup get** command:

   `apicup subsys get <subsystem name>`

   The output from this command lists all of the subsystem settings, including backup, and indicates whether there are any errors. Fix any errors before you continue.

   For SFTP, to view the SSH key, use the **apicup certs** command:

   `apicup certs get ptl site-backup-auth-ssh-key`

3. Validate the installation with the new backup parameters by running the following command:

   `apicup subsys get <subsystem name> --validate`

   Correct any invalid values before you continue.

4. Activate the backup settings by running the following command:

   `apicup subsys install <subsystem name>`

5. Ensure that the changes were applied successfully:

   `apicup subsys health-check <subsystem name>`

[1] PuTTY style keys can be converted to OpenSSH by using the PuTTY Key Generator (PuTTYgen) application; see https://www.puttygen.com/.

Running an on-demand backup of the portal database

When your portal database backup settings are configured, you can use **apicup** to create an on-demand backup of the portal database.

About this task

A complete portal database backup consists of the following items:

- System configuration backup. All configured portal subsystem settings that apply to all sites.
- Site backups. Each portal site has its own database backup.

You can backup the system configuration, the sites, or both.

Important: A portal database backup alone cannot be used for disaster recovery. Ensure that you also always have a recent Project directory backup.

Procedure

1. Ensure that your portal subsystem is healthy:

   `apicup subsys health-check <subsystem name>`

When successful, the command returns silently with an exit code of `0`.

2. Create a backup:

   ```
   apicup subsys backup <subsystem name> <flags>
   ```

   Set *<flags>* according to the type of backup you want:
   - To backup the portal system configuration (and not the sites), specify `--type system`:

     ```
     apicup subsys backup <subsystem name> --type system
     ```

   - To backup a specific portal site or all sites, specify `--type site` and `--site-name`:

     ```
     apicup subsys backup <subsystem name> --type site --site-name <site ID>
     ```

     where *<site ID>* is a specific site UUID or URL, or to backup all sites set `--site-name installed`.
   - To backup the entire portal subsystem (the system and all installed sites), do not specify any flags:

     ```
     apicup subsys backup <subsystem name>
     ```

3. To view your backups and their status:

   ```
   apicup subsys list-backups <subsystem name>
   ```

Restoring the portal database backup

Use the `apicup` command to restore the portal subsystem database.

Before you begin

You must have database backups of both the portal system and portal sites on your remote SFTP server or object-store. See Configuring portal database backups and Running an on-demand backup of the portal database.

To maintain synchronization with the management subsystem, restore the management subsystem database first. The backups of the management and portal databases must be taken at the same time to ensure that the portal sites are consistent with management database.

Important: A portal database backup alone cannot be used for disaster recovery. Ensure that you also always have a recent Project directory backup.

About this task

A complete portal database backup consists of the following items:

- System configuration backup. All the portal subsystem settings that apply to all sites.
- Site backups. Each portal site has its own database backup.

You can restore the system configuration, the sites, or both. If you have a problem with a specific site, it is recommended to restore just that site, and not the complete portal database.

Procedure

1. To view the available backups and their status:

   ```
   apicup subsys list-backups <subsystem name>
   ```

2. Complete a dry-run of the restore.
   To see what restore actions are done when the `apicup subsys restore <subsystem name>` command is run, you can use the `--dry-run` flag:

   ```
   apicup subsys restore <subsystem name> --dry-run --timestamp [now|YYYYMMDD.HHMMSS]
   ```

   Set `--timestamp` to `now` so the newest backup restored. If you want to restore an older backup, you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time (searching backwards from the timestamp).

   Note:
   - With the `--dry-run` option, the utility runs through the restore steps without executing them. You can use this option to see whether the restore from the selected backup would succeed.
     The `--dry-run` option starts with the following output message:

     ```
     Starting restore...please check later for completion status of restore
     PortalRestore is Running
     ```

     To view the results of the dry-run, run:

     ```
     apicup subsys list-restores <subsystem name>
     ```

     Status values can be: `Ready`, `Completed`, `Failed`, or `Running`.
3. Run the restore:

   ```
   apicup subsys restore <subsystem name> --timestamp [now|YYYYMMDD.HHMMSS] [flags]
   ```

   Set `--timestamp` to `now` so the newest backup restored. If you want to restore an older backup, you can specify a timestamp in the format of `YYYYMMDD.HHMMSS` to retrieve the nearest backup file to a specified time (searching backwards from the timestamp).

The restore operation downloads the system backup and all the site backups from the remote server, and then restores them. If a backed up site is already installed, then the site is deleted and replaced with the backup. If you have multiple sites to restore, then these sites are queued for restoration.

- By default the restore is a complete restore of the portal database (system configuration and all sites).
  The restore uses the **priorityList** property that you specified in Configuring portal database backups.
- To restore just the portal system configuration (and not any sites), run the following command:

  ```
  apicup subsys restore <subsystem name> --type system --system-name <arg>
  ```

  where *<arg>* can be a **.tgz** file name or a **backup ID** (if **TYPE=system** and **CR TYPE=record** from the **list-backups** command.)
- To restore just a portal site, run the following command:

  ```
  apicup subsys restore <subsystem name> --type site --site-name <site ID>
  ```

  where *<site ID>* can be the site backup tgz file name or URL.
- To restore all portal sites (but not the portal system configuration), set **--site-name all**.

4. To view your restore and its status, run:

   ```
   apicup subsys list-restores <subsystem name>
   ```

5. To list the portal backup sites, use the portal CLI command. See Using the **sites** commands.
6. To list the portal system sites, use the portal CLI command. See Using the **platforms** commands.

Portal subsystem disaster recovery

Recover the portal subsystem on VMware.

Before you begin

Successful disaster recovery depends on recovery of both the management subsystem and the portal subsystem. To recover a portal deployment after a disaster, you must first recover the management subsystem, and then recover the portal subsystem.

About this task

Recovering the portal subsystem involves re-creating your portal ISO files, redeploying your portal VMs with the new ISO files, and then restoring the portal database from your backup.

Important points:

- In a three replica deployment, if any one VM is corrupted then all the VMs in the cluster must be redeployed. You cannot replace just a single corrupted VM in a cluster.
- The disaster recovery process is intended for restoration of API Connect in the same VMware environment with the same endpoints.
  If you want to restore in a different VMware environment, all configured API Connect endpoints must be valid in the new environment. If the original host name or IP address was not used in any of your API Connect endpoints, then you can give your VMs a different hostname and IP address.

  If you want to change API Connect endpoints or migrate to a different form-factor, see Migrating from v10 to v10 on a different form factor.

All operations must be run from your existing project directory, or a restore of your project directory backup,.

Procedure

1. Re-create your portal ISO files:

   ```
   apicup subsys install <subsystem name> --out <subsystem name>plan-out
   ```

   The **--out** parameter specifies the directory where the ISO files are created. In this example, the ISO files are created in the <project diretory>/*<subsystem name>*plan-out directory.
   Note: If your original ISO files are still available and you did not upgrade from the original installation, you can reuse them. However, if you upgraded your original deployment, you must create new ISO files. For example, do not attempt to deploy v10.0.8.x OVAs with ISO files that were created with **apicup** v10.0.6.0.
   If you are restoring in a different VMware environment, you can change the hostname, IP address, and other properties that you set with **apicup iface create** before you create the ISO files. Use **apicup iface create** to define your new network interface, and then **apicup iface delete** to delete the original one. Do not update any other settings with **apicup**, and if your original VM hostname was used in any of your API Connect endpoints, then you cannot change the hostname.

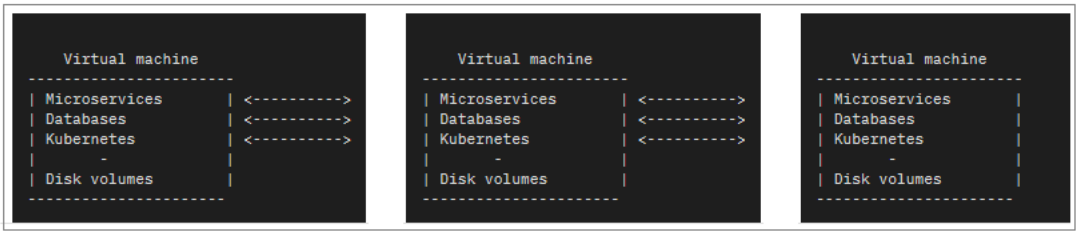
2. Deploy the files into the replacement VMs. See Deploying the portal subsystem OVA.
3. Verify the deployment. See Verifying installation of the portal subsystem.
4. Restore your portal database backup: Restoring the portal database backup.
5. If your created multiple portal endpoints, then recreate the certificates for the endpoints. See Defining multiple portal endpoints for a VMware environment.

Backing up and restoring the analytics subsystem

Backup your analytics subsystem project directory and configure scheduled database backups. The analytics database can be backed up to a remote SFTP server or object-store.

For analytics subsystem backup and restore instructions, see the analytics section: Backing up your analytics subsystem.

Using VM snapshots for infrastructure backup and disaster recovery



You can use VM snapshots to backup and restore API Connect on VMware, and also for infrastructure disaster recovery.

Backup and restore procedures for API Connect on VMware are described in Backing up and restoring on VMware. The standard backup procedures back up all the state that API Connect requires but does not include the underlying infrastructure software.

In some scenarios, you might want to take backups at the infrastructure layer. You can do this by taking snapshots of the virtual machines or underlying storage volumes, providing that you follow the constraints that are described here.

Important: VM snapshots must not be used as an alternative to taking subsystem database backups, a Project directory backup, and a Management certificates backup. Always take and maintain backups of your project directory, management certificates, and subsystem databases.
Ideal times to take VM snapshots are after initial installation and configuration, and before and after upgrades. If your API Connect deployment is lost in a disaster, reverting to the last snapshot and then restoring your subsystem database backups can be faster than the standard Disaster recovery procedures.

- Requirements for taking a consistent backup of an API Connect system at the infrastructure level
  - An API Connect VMware deployment is shown in the following diagram:

  - The API Connect deployment consists of multiple virtual machine images that are running Kubernetes, subsystem databases, and the API Connect micro services. Transactional communication runs between the virtual machines at all levels and all the time, even if the systems appears idle.
  - Within the API Connect deployment, multiple stateful or database layers exist that maintain a consistency protocol. For example `etcd` (upon which Kubernetes is based) uses the Raft consensus algorithm. These algorithms depend for consistency on the basic assertion that time flows forwards on all systems together. If one of the virtual machine's state where to move backwards relative to the others by even the smallest quantum of time, then consistency is lost and the system might fail.

    If VM snapshots are taken across multiple virtual machines, it is certain that these snapshots cannot all be taken at precisely the same time. It is possible that the VM snapshots are restored and might appear to work correctly, but hidden deep within the VMs can be undetected inconsistencies that cause unpredictable errors. These issues can be difficult to diagnose.

    It is also possible that you can test this procedure successfully multiple times and observe no problems. Irrespective of the apparent success of tests, corruption might be present in the system state. For this reason, taking VM snapshots or clones of running API Connect VMs is not supported.

- How to take a consistent backup of an API Connect system at the infrastructure level
  - The only way to take a consistent backup of an API Connect system with VM snapshots and clones is to shut down ALL of the VMs before you take the snapshots or clones.
  - When the VMs are stopped, snapshots can be taken. Clones can be made from the snapshots. The set of clones represent a valid, consistent state that the API Connect system was in when it was shut down.
  - When all the snapshots and clones are taken, the API Connect VMs can be restarted.
- Restoring an API Connect deployment from VM clones:
  - The cloned VMs represent a valid state of the original API Connect deployment. They restart in the same way as the original system restarted.
  - If the objective is to stand up another instance of the cloned API Connect system for testing or DR purposes, the following must be true:
    - The original system and the cloned system must be isolated from one another. The clone uses the same hostnames and IP addresses as the original and so must be stood up in a separate VM hosting environment with Network Address Translation between itself and any network to which the original system is stood up.
    - The cloned system must be stood up in an identical environment in terms of its hardware, software, and network.
- Disaster Recovery by using Disk Replication:
  - A common DR approach is to use disk-based replication. In this case, a storage controller such as IBM's SAN Volume Controller provides Copy Services. You can use Copy Services to create a consistent copy of a set of disks. IBM calls this feature *Synchronous Remote Copy* or *MetroMirror*. Other storage vendors have similar features.
  - If you use Remote Copy to synchronize disk images to a DR site, then IBM supports API Connect used with these systems if the copy at the DR site is consistent. Ensuring this consistency is the responsibility of the storage controller and its configuration. It is **critically important** to ensure that ALL of the disk volumes for all the VMs or nodes in the entire API Connect deployment are in the same remote copy consistency group as shown in the following image. This ensures that DR scenarios do not create inconsistent volumes. If the disks are not in the same consistency group, then the copy is not managed consistently, and the system is not supported.

- Infrastructure-based backup of API Connect using vSphere
  - The following procedure outlines steps to clone a VMware instance of API Connect using the following topology:
    - 3 Management VMs
    - 3 Portal VMs
    - 3 Analytics VMs
    - 3 Gateways
  - Each of these components has a load balancer with its own IP address. The load balancers all sit on a single VM. The cluster is installed and configured on 13 VMs. In this example, the system was populated with data and APIs. These must first be tested to ensure that all published APIs respond as expected. When this is done, use vSphere UI to complete the following steps:
    1. Power off VMs.
       To power off the VMs in sync, schedule a “shutdown guest OS” such that all the VMs shutdown at the same time. Although the shutdown does not occur at the same instant, this does allow the shutdown for every VM to be as close in time as possible.
    2. Take snapshots.
       Take snapshots of each VM after shutdown. Using the scheduling feature in the UI, schedule a snapshot of all the VMs at the same instant. If cloning might adversely affect the system in any way, then the original VMs can be reverted to these snapshots.
    3. Clone VMs.
       Use the clone feature of the UI to create a clone of each VM. This VM must sit in the same resource pool as the original cluster. This is an exact copy of the disks of the original VM. The clones and originals are in no way coupled.
    4. Power on clones.
       Schedule the power-on for each clone VM such that all the clone VMs power on simultaneously. When this is done, test the cluster to ensure that the APIs respond as expected. For the example cluster topology shown earlier on this page, it can take a couple of hours after power-on for all the APIs to respond as expected.

Disaster recovery

Recover your API Connect deployment after a disaster event.

Note: Backups are for recovery of the API Connect subsystems in the same VMware environment where the backups were taken.
If you want to restore API Connect subsystem backups in a different VMware environment, be aware of the following points:

- Every API Connect network endpoint that was defined with **apicup** and all URLs specified in the API Connect UIs must resolve correctly in the new environment. For example, if you configured your platform API endpoint as **`platform.myapiconnect.com`**, that endpoint must be valid in your new environment.

  It is only possible to change endpoints for an API Connect deployment by following the form factor migration procedure.
- If you did not use the original VM hostnames or IP addresses in your API Connect endpoints, then you can deploy your new VMs with different hostnames and IP addresses.

Note: For information about how to maintain a two data center deployment, including failover and recovery procedures, see Maintaining a two data center deployment.
To recover your API Connect deployment after a disaster, follow these steps:

1. If your project directory was lost in the disaster, restore it from your Project directory backup.
2. Restore your management subsystem: Management subsystem disaster recovery.
3. Restore your portal subsystem: Portal subsystem disaster recovery.
4. Restore your analytics subsystem: Analytics subsystem disaster recovery.
5. Restore your gateways.

Disabling and re-enabling the analytics subsystem on VMware

Disable the analytics subsystem by shutting down the VM that hosts it.

Before you begin

This operation requires the use of the Analytics CLI.

About this task

Disabling the analytics subsystem stops the collection and storage of data as well as making the subsystem unavailable.

When you disable analytics, there will be no data in either the API Manager Dashboards or third-party offloads.

Procedure

1. Back up your analytics data as explained in Backing up and restoring the analytics subsystem.
2. Shut down the analytics VMs.
   You can shut down the VMs using one of the following methods:
   - Use the VMware console
   - **`ssh`** into the images and run the **`shutdown`** command

Re-enabling analytics

3. Start your analytics VMs.

Maintaining a two data center deployment

How to maintain a two data center disaster recovery (DR) deployment on VMware, including information about normal operation, failure handling, and recovery.

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see Two data center warm-standby deployment strategy on VMware.

See the following topics for information about failure handling, backup, upgrade, and removing a 2DCDR deployment.

- **Backup and restore considerations for a two data center deployment**
  Points to consider when you configure backups and restoring a two data center disaster recovery (2DCDR) deployment on VMware.
- **How to failover a two data center deployment**
  If a failure occurs in your active data center, then failover to your warm-standby data center.
- **Removing a two data center deployment**
  You can remove your two data center disaster recovery deployment on VMware.

- Installing a two data center deployment

Backup and restore considerations for a two data center deployment

Points to consider when you configure backups and restoring a two data center disaster recovery (2DCDR) deployment on VMware.

The 2DCDR backup requirements are different for the portal and management subsystems.

Management 2DCDR backup requirements

- Different remote backup locations must be specified for each data center.
- Both active and warm-standby management subsystems run the scheduled backup job.
- To restore a backup, 2DCDR must be disabled first.

Portal 2DCDR backup requirements

- The backup settings for both the active and warm-standby portal must be identical.
- Only the active data center portal takes backups. On failover, the backup job of the new warm-standby is disabled, and the backup job of the new active is enabled.
- Portal restores are only done on the active data center.

Configuring backups for 2DCDR deployments

Keeping the different portal and management 2DCDR backup requirements in mind, the actual steps for configuring backups for both subsystems are the same as for a single API Connect deployment: Backing up and restoring on VMware.

Related concepts

- Two data center warm-standby deployment strategy on VMware

Related tasks

- Installing a two data center deployment

How to failover a two data center deployment

If a failure occurs in your active data center, then failover to your warm-standby data center.

Before you begin the failover process, first confirm that failover is the correct action to take.

Failover to the warm-standby is the appropriate action to take in the following circumstances:

- The failure is with the active data center itself, for example:
  - All VMs in the active data center are down.
  - Network connectivity to the active data is down.
- The API Connect deployment in the active data center is in a failed state. For example, the `health-check` command returns errors, and you are not able to resolve these errors.

  ```
  apicup subsys <subsystem name> health-check
  ```

The failover steps that you must follow depend on the condition of your active data center:

- **Failover steps when active site is responsive**
  Demote your active data center to warm-standby, and then promote your warm-standby data center to active.
- **Failover steps when active site is inaccessible**
  Disable network access to your failed active data center, and promote your warm-standby data center to active.

Failover steps when active site is responsive

Demote your active data center to warm-standby, and then promote your warm-standby data center to active.

About this task

The steps in this topic cover how to complete a failover in the following scenarios:

- When the active management and portal subsystems are in a healthy state.
- The problem that the active management or portal subsystem has (that requires the failover) does not prevent the running of the **apicup** commands that are necessary to convert the active to warm-standby.

If the active site is not accessible, or responsive to **apicup** commands, then refer to Failover steps when active site is inaccessible.
For both management portal subsystems, the order in which failover is done is critical to prevent an active-active scenario that can cause a split-brain. The first step in failover is to demote the active data center to warm-standby, confirm that this demotion was successful, and then promote the original warm-standby to active.

In the steps provided in this topic, the active data center is called DC1, and the warm-standby data center is called DC2.

Procedure

- **Management subsystem failover**
  1. Set DC1 to be warm-standby.
     a. Set the `multi-site-ha-mode` property to `passive` in DC1:

        ```
        apicup subsys set <DC1 management> multi-site-ha-mode=passive
        ```

     b. Apply the update to DC1:

        ```
        apicup subsys install <DC1 management> --accept-dr-data-deletion
        ```

        Note: When an active management subsystem is converted to warm-standby, all contents of its management database are deleted (to be replaced by the contents from the other data center when it becomes the active). The `--accept-dr-data-deletion` flag is acknowledgment that you accept this temporary loss of data.
     c. Monitor the progress of the conversion to warm-standby:

        ```
        apicup subsys health-check <DC1 management> -v
        ```

     Important: If the management subsystem does not successfully convert to warm-standby, then do not proceed any further. Treat DC1 as an inaccessible data center, and refer to Failover steps when active site is inaccessible.
  2. Set DC2 to be the active data center.
     a. Confirm that DC2 is ready for promotion to active:

        ```
        apicup subsys health-check <DC2 management> -v
        ```

        Output should show:

        ```
        ...
        ReadyForPromotion
        ...
        ```

b. Set the `multi-site-ha-mode` property to `active` in DC2:

```
apicup subsys set <DC2 management> multi-site-ha-mode=active
```

c. Apply the update to DC2:

```
apicup subsys install <DC2 management> --skip-health-check
```

3. Monitor the failover process:

```
apicup subsys health-check <subsystem name>
```

When failover is complete the health-check command returns no output in either data center. Use the `-v` flag to see more information:

```
apicup subsys health-check <subsystem name> -v
```

4. Update your dynamic router to redirect all management subsystem traffic to DC2 instead of DC1.

- **Developer Portal service failover**
  The following instructions show how to failover DC1 to DC2 for the Developer Portal service. If you have multiple portal services, then you must repeat these steps for each Developer Portal service that you want to failover.

1. Set DC1 to be warm-standby.
   a. Set the `multi-site-ha-mode` property to `passive` in DC1:

```
apicup subsys set <DC1 portal> multi-site-ha-mode=passive
```

   b. Apply the update to DC1:

```
apicup subsys install <DC1 portal> --skip-health-check
```

   c. Monitor the progression to warm-standby
      i. Login to one of the portal VMs in DC1 using SSH:

```
ssh apicadm@<portal hostname>
```

      ii. Switch to root user:

```
sudo -i
```

      iii. Run `kubectl describe ptl`, and look for `HA Mode` in the `Status` section of the output:

```
kubectl describe ptl

...
Status:
  ...
  HA Mode: progressing to passive
```

When `Status.HA Mode` shows `progressing to passive`, set portal in DC2 to be active, as described in step 2.

Warning: The `Spec` section of the output also has an `HA mode` property, take care to ensure that you are checking the `HA mode` in the `Status` section.

2. Set DC2 to be active.
   a. Set the `multi-site-ha-mode` property to `active` in DC2:

```
apicup subsys set <DC2 portal> multi-site-ha-mode=active
```

   b. Apply the update in DC2:

```
apicup subsys install <DC2 portal> --skip-health-check
```

3. Monitor the failover process:

```
apicup subsys health-check <subsystem name>
```

When failover is complete the health-check command returns no output in either data center. Use the `-v` flag to see more information:

```
apicup subsys health-check <subsystem name> -v
```

4. Update your dynamic router to redirect all traffic to DC2 instead of DC1.

Results

How long it takes to complete the failover varies, and depends on hardware speed, network latency, and the size of the databases. However, here are some approximate timings:

For the management subsystem:

- `warm-standby` to `active` approximately 5 minutes
- `active` to `warm-standby` approximately 15 minutes

For the portal subsystem:

- `warm-standby` to `active` 15 - 40 minutes
- `active` to `warm-standby` approximately 10 minutes

Failover steps when active site is inaccessible

Disable network access to your failed active data center, and promote your warm-standby data center to active.

About this task

Follow the steps in this procedure when your active site is inaccessible, or the API Connect subsystems in your active site are not responding to **apicup** operations.

Procedure

1. Update the network configuration in your failed data center to isolate the API Connect subsystems in this data center, so that they cannot communicate with each other, nor with the warm-standby data center. Network isolation is necessary to prevent a split-brain situation, which occurs if your active site recovers unexpectedly and starts communicating with your other subsystems.
2. Promote your warm-standby management subsystem to active:

   ```
   apicup subsys set <mgmt_subsystem> multi-site-ha-mode=active
   ```

   Apply the change with:

   ```
   apicup subsys install <mgmt_subsystem> --force-promotion --skip-health-check
   ```

   Monitor the progress of the promotion with:

   ```
   apicup subsys health-check <mgmt_subsystem>
   ```

   when the command returns no output, the promotion to active is complete.
   Use the `-v` flag to see more information:

   ```
   apicup subsys health-check <subsystem name> -v
   ```
3. Promote your warm-standby portal subsystem to active:

   ```
   apicup subsys set <portal_subsystem> multi-site-ha-mode=active
   ```

   Apply the change with:

   ```
   apicup subsys install <portal_subsystem>
   ```

   Monitor the progress of the promotion with:

   ```
   apicup subsys health-check <mgmt_subsystem>
   ```

   when the command returns no output, the promotion to active is complete.
   Use the `-v` flag to see more information:

   ```
   apicup subsys health-check <subsystem name> -v
   ```
4. Update your dynamic router to redirect all traffic to DC2 instead of DC1.

What to do next

If API Connect in your failed data center cannot be recovered, do not leave your remaining data center as a 2DCDR active with no functioning warm-standby. You have the following options:

- Convert your remaining data center to a stand-alone, and continue with one data center. See Removing a two data center deployment.
- Install a new warm-standby data center to replace the failed one. See Installing a two data center deployment.

If you are able to recover your failed data center, before you re-enable network access, set the management and portal subsystems to warm-standby:

1. Set the `multi-site-ha-mode` property to `passive` for the management subsystem in DC1:

   ```
   apicup subsys set <DC1 management> multi-site-ha-mode=passive
   ```
2. Apply the update to DC1:

   ```
   apicup subsys install <DC1 management> --accept-dr-data-deletion
   ```

   Note: When an active management subsystem is converted to warm-standby, all contents of its management database are deleted (to be replaced by the contents from the other data center when it becomes the active). The `--accept-dr-data-deletion` flag is acknowledgment that you accept this temporary loss of data.
3. Monitor the progress of the conversion to warm-standby:

   ```
   apicup subsys health-check <DC1 management> -v
   ```
4. Set the `multi-site-ha-mode` property to `passive` for the portal subsystem in DC1:

   ```
   apicup subsys set <DC1 portal> multi-site-ha-mode=passive
   ```
5. Apply the update to DC1:

   ```
   apicup subsys install <DC1 portal> --skip-health-check
   ```
6. Monitor the progress of the conversion to warm-standby:

   ```
   apicup subsys health-check <DC1 portal> -v
   ```
7. When you have confirmed that both management and portal subsystems in DC1 are set to warm-standby, you can re-enable the network to the DC1 API Connect subsystems, and the two data centers should synchronize their API Connect data.
   Monitor the health at both data centers with:

   ```
   apicup subsys health-check <DC1 management> -v
   ```

Removing a two data center deployment

You can remove your two data center disaster recovery deployment on VMware.

Before you begin

Ensure that you understand the concepts of a 2DCDR deployment in API Connect. For more information, see Two data center warm-standby deployment strategy on VMware.

About this task

If you decide to remove your two data center disaster recovery (DR) deployment, you go from two data centers to one. The active data center remains as the only working system. The warm-standby data center has its data deleted.

Warning: If the active data center is offline, do not disable 2DCDR in the warm-standby data center, as this action deletes all the data from the management and portal databases.
As part of the installation, you configured the `multi-site-ha` settings on each data center, as described in the following table:

Table 1. The `multi-site-ha` settings

Setting	Description
`multi-site-ha-enabled`	Indicates whether two data center DR deployment is enabled. Set to `true` to enable two data center DR. Set to `false` to disable two data center DR. The default value is `false`.
`multi-site-ha-mode`	The state of the data center in the context of the two data center deployment. Valid values are: • `active` - indicates the primary data center • `passive` - indicates the warm-standby data center
`management-replication`	Required only for the management subsystem. The external ingress name for the management subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`portal-replication`	Required only for the portal subsystem. The external ingress name for the portal subsystem in the current data center in the two data center deployment. The name is a unique fully qualified hostname that the other data center uses to communicate with the current data center.
`replication-peer-fqdn`	The ingress hostname for the other data center in the two data center deployment. This information is required so that the two data centers can communicate with each other.

If you want to revert to a single data center topology, or temporarily remove the warm-standby data center from DR, you must disable the `multi-site-ha` configuration on the active data center, and then remove the warm-standby data center. If the active data center is offline, you must first change the warm-standby data center to be active, and then disable the `multi-site-ha` configuration on the now active data center.

Procedure

- Disable the `multi-site-ha` configuration on the active data center:
  1. Disable the `multi-site-ha` configuration on the management subsystem of the active data center:

     ```
     apicup subsys set mgmt multi-site-ha-enabled=false
     apicup subsys install mgmt
     ```

  2. Disable the `multi-site-ha` configuration on the portal subsystem of the active data center:

     ```
     apicup subsys set ptl multi-site-ha-enabled=false
     apicup subsys install ptl
     ```

- Disable the `multi-site-ha` configuration on the warm-standby data center:
  Note:
  Disabling 2DCDR on the warm-standby results in deletion of all data on the warm-standby.

  If you do not plan to keep the warm-standby installation, you can uninstall API Connect on the warm-standby, you do not need to convert it to a stand-alone before you uninstall.
  1. Disable the `multi-site-ha` configuration on the management subsystem of the warm-standby data center:

     ```
     apicup subsys set mgmt multi-site-ha-enabled=false
     apicup subsys install mgmt --accept-dr-data-deletion
     ```

  2. Disable the `multi-site-ha` configuration on the portal subsystem of the warm-standby data center:

     ```
     apicup subsys set ptl multi-site-ha-enabled=false
     apicup subsys install ptl
     ```

Related concepts

Monitoring and health checks

Monitor your deployment and complete health checks on subsystems.

See:

- **Checking cluster health on VMware**
  You can use **apicup** to check the health of the API Connect clusters in your VMware deployment.
- **Monitoring Postgres disk usage on VMware**
  Monitor disk usage by the Postgres database in the management subsystem, when deployed on VMware.
- **Obtaining simple health check data of Developer Portal sites by using a REST API call**
  Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.
- **Monitoring with SNMP**
  Presents a table of OID trees that you can poll using SNMP Get.

Checking cluster health on VMware

You can use **apicup** to check the health of the API Connect clusters in your VMware deployment.

The **health-check** command checks a number of criteria to determine the health of their cluster. When all criteria are successfully met, the command displays no output, and exits with a status of **0**. When one or more criteria are not met, the command stops processing and displays a message with the failure and exits with a status of **1**.

The command takes no arguments. The only option is the **--verbose** flag. If **--verbose** is set the command prints all checks that were performed.

The **health-check** is run against the namespace that is specified in apiconnect-up.yaml.

The health check is run on the specified subsystem.

The command verifies that for the specified subsystem:

- The **apicup** version matches the API Connect release version.
- All cluster members are running the same API Connect release version.
- All cluster members have a deployment status of **Done**.
- Docker is running.
- **kubelet** is running
- All Kubernetes-defined nodes are running.
- The Kubernetes Control Plane pods are running:
  - **etcd/kube-apiserver**
  - **kube-system.kube-controller**
  - **kube-scheduler**
  - **kube-apiserver-proxy**
- The add-on Kubernetes Deployments are fulfilled:
  - **coredns**
  - **metrics-server**
- The add-on Kubernetes DaemonSets are fulfilled:
  - **calico-node**
  - **ingress-nginx-ingress-controller**
  - **kube-proxy**

Syntax:

```
Usage:
  apicup subsys health-check <SUBSYS>  [flags]

Flags:
  -h, --help                help for health-check
      --kubeconfig string   (optional) absolute path to the kubeconfig file (default "/Users/<username>/.kube/config")
  -v, --verbose             Verbose output

Global Flags:
      --accept-license   Accept the license for API Connect
      --debug            Enable debug logging
```

Example usage, for a subsystem named **mgmt**:

```
../apicup subsys health-check mgmt
```

Note:

- The command flag **--kubeconfig string** does not apply to deployments on VMware.
- In a multi-node OVA cluster, the **apicup subsys health-check** command does not return status information if a majority of the nodes are down. To obtain status information, start more nodes. Status is returned only when a quorum is achieved.

Monitoring Postgres disk usage on VMware

Monitor disk usage by the Postgres database in the management subsystem, when deployed on VMware.

Postgres Database is the core database used in Management Subsystem. It is important to monitor the Postgres disk usage.

The APIConnect operator tracks the current disk usage of the Postgres components, and regularly updates **apic health-check** command.

APIConnect operator regularly updates the **ManagementCluster** instance status which is reflected in the **apic health-check** command.

apic health-check command reports WARNING state when disk utilization reaches 60%.

apic health-check command reports ERROR state when disk utilization reaches 70% and Postgres is brought down.

Management Cluster disk stats

The **ManagementCluster** instance has **.status.postgresDataStats** where the operator prints the current disk usage of Postgres components. Use **kubectl** to view the status.

To use **kubectl**, first ssh into the appliance as **root**.

```
kubectl get mgmt -o json | jq .status.postgresDataStats
[
  {
    "instanceName": "management-site1-db-1",
    "podName": "",
    "pvcCapacity": 51200,
    "pvcName": "",
    "pvcType": "WAL",
    "pvcUsed": 400,
    "pvcUsedPercentage": 8
  },
  {
    "instanceName": "management-site1-db-1",
    "podName": "",
    "pvcCapacity": 184320,
    "pvcName": "",
    "pvcType": "PostgreSQL",
    "pvcUsed": 95,
    "pvcUsedPercentage": 8
  }
]
```

Warning condition is populated at 60% usage

When one of the Postgres components occupy 60% usage, the operator marks the overall status of the **ManagementCluster** to **Warning** with an appropriate warning message, which is included in the output from **apic health-check** command.

The warning condition explains why the warning condition was set.

To use **apic**, first ssh into the appliance as **root**.

```
apic health-check
```

```
FATA[0007] Cluster not in good health:
ManagementCluster is not Ready or Complete | State: 17/17 Phase:
  Warning Message: Current WAL disk usage of nihar-stac-3955b42d-site1-postgres is 61 percent.
  DATABASE SHUTDOWN starts at 70 percent utilization. Please contact IBM Support immediately
```

If you encounter the warning, contact IBM support to fix the root cause.

Error condition is populated at 70% usage

An error condition is populated when the operator brings down Postgres because it is using 70% of available disk space. Postgres is brought down to avoid problems, such as disk corruption, that can occur if the disk becomes completely filled.

To use **apic**, first ssh into the appliance as **root**.

```
apic health-check
```

```
FATA[0011] Cluster not in good health:
ManagementCluster is not Ready or Complete | State: 17/17 Phase:
  Error Message: Current WAL disk usage of nihar-stac-3955b42d-site1-postgres is more than 70 percent,
  initiating DATABASE SHUTDOWN
```

If you encounter the error, contact IBM support to fix the root cause.

Important:
On VMware, because the entire disk is allocated to the worker node, in some cases before the operator reacts to 70% usage, , Kubernetes itself can face disk pressure and starts evicting pods. In these cases, increase the disk allocated to worker node in order to stabilize the worker node. See Adding disk space to a VMware appliance.

Obtaining simple health check data of Developer Portal sites by using a REST API call

Call a simple health check API from your external load balancer to dynamically determine whether a specific Developer Portal site in a cluster is working. This API call can be used by a load balancer to help determine where to route traffic.

About this task

You can use the site health REST API to determine whether a particular Developer Portal site is running. The site health API returns the current system time of the site if both the database and web server are running. This API is fast and puts no load on the system, so it is ideal for use with load balancers to help them determine where to route traffic.

Procedure

To call the site health REST API, append **/health** to the end of your Developer Portal site URL in your web browser, as follows:

***site_url*/health**

Where ***site_url*** is the URL of the Developer Portal site that you want to check.
If both the database and web server of the site are running, the web browser returns the current system time. For example:

```
1511367695
```

If either the database or the web server of the site is not running, the web browser returns an error that the site can't be reached.
If you do get an error from the **/health** endpoint, refer to gather logs and obtain the **portal-www web** logs, so that you can see more information on the error.

Monitoring with SNMP

Presents a table of OID trees that you can poll using SNMP Get.

Simple Network Management Protocol (SNMP) collects information from network devices, such as servers, printers, hubs, switches, and routers on an Internet Protocol (IP). SNMP employs addresses for network devices using a hierarchical numbering system called Object Identifiers (OID). The following table provides OID addresses for polling in SNMP to monitor API Connect servers.

Note:

- Only SNMP v2 and SNMP v3 are supported. However, it is not recommended to enable SNMP v2. Instead, configure SNMPv3 as shown in Configuring SNMPv3, and then enable it as shown in Enabling SNMP.
- If the server has two or more network interfaces, the SNMP request is sent only to the first network interface.
- SNMP is disabled by default for all hosts.
- This information applies to API Connect deployments in VMware environments. It does not apply to Kubernetes deployments.

Each entry in the table represents many individual items. Use snmpwalk or another SNMP polling utility to see the complete list. You can poll the following OID trees:

Table 1. Default SNMPv2 configuration

OID	SNMP Name	Notes
.1.3.6.1.2.1.1	SNMPv2-MIB::system	
.1.3.6.1.2.1.2	IF-MIB::interfaces	
.1.3.6.1.2.1.4	IP-MIB::ip	
.1.3.6.1.2.1.5	IP-MIB::icmp.	
.1.3.6.1.2.1.6	TCP-MIB::tcp	
.1.3.6.1.2.1.7	UDP-MIB::udp	
.1.3.6.1.2.1.11	SNMPv2-MIB::snmp	
.1.3.6.1.2.1.25.1	HOST-RESOURCES-MIB::hrSystem	Excluding .1.3.6.1.2.1.25.1.3 HOST-RESOURCES-MIB::hrSystemInitialLoadDevice Excluding .1.3.6.1.2.1.25.1.4 HOST-RESOURCES-MIB::hrSystemInitialLoadParameters
.1.3.6.1.2.1.25.2	HOST-RESOURCES-MIB::hrStorage	
.1.3.6.1.2.1.25.3	HOST-RESOURCES-MIB::hrDevice	
.1.3.6.1.4.1.2021.4	UCD-SNMP-MIB::memory	
.1.3.6.1.4.1.2021.10	UCD-SNMP-MIB::laTable	CPU Load Average
.1.3.6.1.4.1.2021.11	UCD-SNMP-MIB::systemStats	

Configuring SNMPv3

From an OVA shell prompt as root edit the file **/etc/snmp/snmpd.conf** so that its content is:

```
createUser readOnlyUser SHA authpassphrase AES privpassphrase
rouser readOnlyUser
agentAddress udp:161,udp6:[::1]:161
```

- Replace ***authpassphrase*** with the passphrase to be used for authentication,
- Replace ***privpassphrase*** with the passphrase to be used for privacy (encryption) of the communications.

Enabling SNMP

It is not recommended to start SNMP without first configuring it for SNMPv3. See Configuring SNMPv3.

Enable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl start snmpd
systemctl enable snmpd
```

Sample output:

```
root@mgmt:~# systemctl start snmpd
root@mgmt:~# systemctl enable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install enable snmpd
insserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
insserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

Disabling SNMP

Disable SNMP on each individual OVA node with the following commands from an OVA shell prompt as root:

```
systemctl stop snmpd
systemctl disable snmpd
```

Sample output:

```
root@mgmt:~# systemctl stop snmpd
root@mgmt:~# systemctl disable snmpd
snmpd.service is not a native service, redirecting to systemd-sysv-install
Executing /lib/systemd/systemd-sysv-install disable snmpd
insserv: warning: current start runlevel(s) (empty) of script `snmpd' overrides LSB defaults (2 3 4 5).
insserv: warning: current stop runlevel(s) (0 1 2 3 4 5 6) of script `snmpd' overrides LSB defaults (0 1 6).
```

Checking SNMP status

Check whether SNMP is enabled on each individual OVA node with the following commands from an OVA shell prompt:

```
systemctl status snmpd
```

Sample output when SNMP is enabled and running:

```
apicadm@mgmt:~$ systemctl status snmpd
  snmpd.service - LSB: SNMP agents
   Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
   Active: active (running) since Wed 2019-02-06 03:53:02 UTC; 2 days ago
     Docs: man:systemd-sysv-generator(8)
    Tasks: 1
   Memory: 6.0M
      CPU: 3min 1.641s
   CGroup: /system.slice/snmpd.service
           └─1366 /usr/sbin/snmpd -Lsd -Lf /dev/null -u snmp -g snmp -I -smux mteTrigger mteTriggerConf -p /run/snmpd.pid
...
```

Sample output when SNMP is stopped and disabled:

```
root@mgmt:~# systemctl status snmpd
   snmpd.service - LSB: SNMP agents
   Loaded: loaded (/etc/init.d/snmpd; bad; vendor preset: enabled)
   Active: inactive (dead)
     Docs: man:systemd-sysv-generator(8)
...
```

Logging

Configure logging for your deployment on VMware.

See:

- **Configuring remote logging for a VMware deployment**
  Logging collection is required for IBM Support to assist with troubleshooting. You can configure fluent-bit to collect and forward logs to a remote Syslog server.
- **Gathering logs in a VMware environment**
  How to gather the API Connect system logs and configuration information for use in troubleshooting and diagnostics.
- **Changing logging levels**
  You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

Configuring remote logging for a VMware deployment

Logging collection is required for IBM Support to assist with troubleshooting. You can configure fluent-bit to collect and forward logs to a remote Syslog server.

Before you begin

The fluent-bit service is already installed on the appliances and is configured to forward container logs to /var/log/syslog on the local machine.

Important: This article refers to third-party software that IBM does not control. As such, the software may change and this information might become outdated. In addition, the fluent-bit service was tested only for simple container log routing to local and remote Syslog servers as configured in the instructions that follow. Any customization of other fluent-bit settings (for example, to set up parsers or filters) is at your own risk and should be performed with caution by referring to the fluent-bit documentation.

About this task

Remote logs created with fluent-bit use the following format:

```
Mar 1 00:38:44 apicdev1147 calico-node-gqbv_42428a8ade169ad3 2023-03-01 00:38:44.684 [INFO][208] felix/int_dataplane.go 1245:
Applying dataplane updates
```

Where:

- `Mar 1 00:38:44` is the time the log arrived on the remote server.
- `apicdev1147` is the hostname of the log source.
- `calico-node-gqbv_42428a8ade169ad3` is a portion of the pod name/container_id where the log is coming from.
- `2023-03-01 00:38:44.684` is the timestamp at which the logged event actually took place within the container.
- The rest of the log is the log message itself.

Logs posted to your local server look different, as in this example:

```
Feb 28 23:47:03 apicdev1147 fluent-bit[2332273]: [2] kube.var.log.containers.kqn2-management-portal-proxy-647b96b89f-
pkz5w_default_portal-proxy-74a1723512574fdc23fb9c014b80c7e83aff225b9d44d995736251edd18c49b4.log: [1677628023.503190040,
{"_p"=>"F", "log"=>"Tue, 28 Feb 2023 23:47:03 GMT express:router expressInit  : /healthz", "tag"=>"kqn2-management-
_74a1723512574fdc", "time"=>"2023-02-28T23:47:03.503190005Z", "stream"=>"stderr"}]
```

On the local log, the whole fluent-bit JSON object is logged, which provides slightly more information (for example, the full file name of the log file) than in the remote log.

To configure remote logging, use the appropriate instructions for your deployed version of API Connect:

- Configuring remote logging
- Updating the remote logging configuration

Configuring remote logging

About this task

The fluent-bit service is already installed on the appliance and is configured to forward container logs to `/var/log/syslog` on the local machine. If you want to change the output destination to a remote Syslog server, complete the following steps:

Procedure

1. Create the /etc/fluent-bit/append-tag.lua file.
   a. Paste the following code into the new file:

```
function append_tag(tag, timestamp, record)
    new_record = record
    local pod_name = string.sub(string.match(tag, "^kube%.var%.log%.containers%.(.+)$"), 1, 16)
    local container_id = string.sub(string.match(tag, "-([^-]+)%.log$"), 1, 16)

    new_record["tag"] = pod_name .. "_" .. container_id
    return 1, timestamp, new_record
end
```

   b. Save and close the file.
2. Create the /etc/fluent-bit/fluent-bit-override.conf file.
   a. Add the following statements to the new file::
   Replace the variables in the `[OUTPUT]` section with values for your deployment:

```
[SERVICE]
        Daemon Off
        Flush 1
        Log_Level info
        Parsers_File parsers.conf
        HTTP_Server On
        HTTP_Listen 0.0.0.0
        HTTP_Port 2021
        Health_Check On

[INPUT]
        Name tail
        Path /var/log/containers/*.log
        multiline.parser docker, cri
        Tag kube.*
        Mem_Buf_Limit 5MB
        Skip_Long_Lines On

[INPUT]
        Name systemd
        Tag host.*
        Systemd_Filter _SYSTEMD_UNIT=kubelet.service
        Read_From_Tail On

[FILTER]
        Name kubernetes
        Match kube.*
        Merge_Log On
        Keep_Log Off
        K8S-Logging.Parser On
        K8S-Logging.Exclude On

[FILTER]
        Name lua
        Match kube.*
        Script /etc/fluent-bit/append-tag.lua
        call append_tag

[OUTPUT]
        Name syslog
        Match *
        Host <host>
        port 514
        mode udp
        syslog_format rfc5424
```

```
        syslog_maxsize 2048
        syslog_hostname_key hostname
        syslog_hostname_preset <hostname of local machine/log source>
        syslog_appname_key tag
        syslog_message_key log
```

Note: The default values shown in the `[OUTPUT]` section can be modified as explained in the fluent-bit documentation.

b. Save and close the file.

3. Run the following command to restart the fluent-bit service so it picks up the configuration changes:

```
systemctl restart appliance-manager && systemctl restart fluent-bit
```

Updating the remote logging configuration

To update the fluent-bit configuration, complete the following steps:

Procedure

1. Run the following command to edit the configuration file:

```
vim /etc/fluent-bit/fluent-bit-override.conf
```

2. Complete your configuration changes, then save and close the file.
3. Run the following command to restart the appliance-manager:

```
systemctl restart appliance-manager
```

Gathering logs in a VMware environment

How to gather the API Connect system logs and configuration information for use in troubleshooting and diagnostics.

When you open a support case for API Connect, system logs and environment data are normally required to help diagnosis. Several tools are used for gathering this data:

- The apic-mustgather tool tool collects all the logs and system information from the management, portal, and analytics VMs.
- The apicops tool gathers extra debug information about the synchronization of the management subsystem with the gateways.
- DataPower error reports and debug logs provide the information that is required from the gateway appliance.

Installing the apic-mustgather tool

Download the latest version of the apic-mustgather tool from https://github.com/ibm-apiconnect/v10-postmortem/releases/latest/download/apic-mustgather, copy it to your API Connect VMs, and give it execute permissions. For example:

```
curl -L -O https://github.com/ibm-apiconnect/v10-postmortem/releases/latest/download/apic-mustgather
```

```
scp apic-mustgather apicadm@<API Connect VM hostname>:/home/apicadm
```

```
ssh apicadm@<API Connect VM hostname>
```

```
sudo chmod +x apic-mustgather
```

Important: If you downloaded this tool previously, check that you still have the latest version:

```
sudo ./apic-mustgather --version
```

The **apic-mustgather** tool gathers OS-level information from each VM, so if you have a three replica API Connect deployment, it is recommended to install and run the **apic-mustgather** tool on each VM in the cluster.

The **apic-mustgather** tool gathers the logs of the currently running processes. The logs have a maximum size and older log messages are not retained when the maximum size is reached. To ensure that the logs gathered cover the time when the problem occurred, reproduce the problem and then gather the logs without delay. Offboarding the logs to an external server is the best practice for long-term storage of log data. See Configuring remote logging for a VMware deployment.

Gathering the management subsystem data on VMware

1. Install the **apic-mustgather** tool and apicops on all your management VMs.
2. Re-create the problem that you want to diagnose.
3. On each API Connect VM, run the following commands:

```
sudo ./apic-mustgather
```

```
sudo apic status > apic_status.out
```

```
sudo apic version > apic_version.out
```

4. Copy off the generated files from each VM:
   - /tmp/apic-mustgather-*.tar.gz (**apic-mustgather** tool output)
   - apic_status.out
   - apic_version.out
5. Create an archive of your project directory:

```
sudo tar -cf projectdir.tar <project directory path>
```

6. Upload the files to the support case:
   - /tmp/apic-mustgather-*.tar.gz (**apic-mustgather** tool output)

- apic_status.out
- apic_version.out
- `projectdir.tar`

Gathering the portal subsystem data on VMware

1. Install the `apic-mustgather` tool and apicops on all your management VMs.
2. Re-create the problem that you want to diagnose.
3. On each API Connect VM, run the following commands:

```
sudo ./apic-mustgather
```

```
sudo apic status > apic_status.out
```

```
sudo apic version > apic_version.out
```

4. Copy off the generated files from each VM:
   - /tmp/apic-mustgather-*.tar.gz (**apic-mustgather** tool output)
   - apic_status.out
   - apic_version.out
5. Create an archive of your project directory:

```
sudo tar -cf projectdir.tar <project directory path>
```

6. Upload the files to the support case:
   - /tmp/apic-mustgather-*.tar.gz (**apic-mustgather** tool output)
   - apic_status.out
   - apic_version.out
   - `projectdir.tar`

Gathering the analytics subsystem data on VMware

1. Install the `apic-mustgather` tool and apicops on all your management VMs.
2. Re-create the problem that you want to diagnose.
3. On each API Connect VM, run the following commands:

```
sudo ./apic-mustgather
```

```
sudo apic status > apic_status.out
```

```
sudo apic version > apic_version.out
```

4. Copy off the generated files from each VM:
   - /tmp/apic-mustgather-*.tar.gz (**apic-mustgather** tool output)
   - apic_status.out
   - apic_version.out
5. Create an archive of your project directory:

```
sudo tar -cf projectdir.tar <project directory path>
```

6. Upload the files to the support case:
   - /tmp/apic-mustgather-*.tar.gz (**apic-mustgather** tool output)
   - apic_status.out
   - apic_version.out
   - `projectdir.tar`

Gathering the DataPower appliance subsystem data

Before you reproduce the problem, configure DataPower and management subsystem logging as described in the following steps:

1. Use SSH to log in to each gateway and access the DataPower CLI. For more information about accessing the DataPower CLI, see *Command-line access* in the DataPower documentation.
2. Configure the log target in the API Connect application domain. Repeat these steps for each gateway server in the cluster:

```
sw <apiconnect domain>
configure terminal
logging target gwd-log
type file
format text
timestamp zulu
size 50000
local-file logtemp:///gwd-log.log
event apic-gw-service debug
exit
apic-gw-service;admin-state disabled;exit
apic-gw-service;admin-state enabled;exit
write mem
exit
```

3. OPTIONAL: Enable debug of gateway-peering on each gateway.

```
sw <apiconnect domain>
diagnostics
gateway-peering-debug <gw peering object name>
exit
```

Replace *<gw peering object name>* with the correct name of the peering object. To identify the peering object name, run the following command within the API Connect domain:

```
show gateway-peering-status
```

4. Install the **apic-mustgather** tool and apicops on all of your management subsystem VMs.

Reproduce the problem, taking note of the exact time of the reproduction, and then follow these steps to gather the logs:

1. Gather the management subsystem logs, following the steps in Gathering the management subsystem data on VMware.
2. On one of the management VMs, run the apicops command and collect the output:

   ```
   ./apicops debug:info
   ```

3. Generate an error-report on each gateway in your gateway cluster:

   ```
   sw default
   conf; save error-repor
   ```

4. If you enabled gateway peering debug, then get the log file and disable debug logging. Run the following command for each gateway in the cluster. Replace *<gw peering object name>* with the correct peering object name.

   ```
   sw <apiconnect domain>
   diagnostics
   gateway-peering-dump <gw peering object name>
   no gateway-peering-debug <gw peering object name>
   exit
   ```

   To identify the *<gw peering object name>*, run the following command within the API Connect domain:

   ```
   show gateway-peering-status
   ```

Upload the following to the support case:

- Management subsystem **apic-mustgather** and **apicops** output.
- Gateway service logs: Upload the logs at logtemp://gwd-log.log within the API Connect domain.
- Gateway error reports: Include the error report file named <error report filename>.txt.gz.
- If you enabled gateway peering debug, then upload gatewaypeering.log and gatewaypeeringmonitor.log from temporary:///<name of gateway peering object in API Connect application domain>.
- Optional: Other data for troubleshooting specific APIs:
  - Temporary files: Include all relevant files that are located under temporary://.
  - Configuration and YAML Files: Upload YAML files related to the failing API and the DataPower configuration for the application domain.
  - Transaction Probes: Provide data from the probe of the failing transaction as outlined in the API probe configuration instructions.
- Optional: Special considerations for v5-compatible gateways:
  - YAML Files: Include related YAML files.
  - Transaction probes: Upload data from the probe of the failing transaction.
  - Document cache: Provide an export of the document cache for **webapi** and **webapi-internal**.

Important: Ensure to update the support case with the date and time of when the problem occurred or was reproduced.

Changing logging levels

You can enable logging for entry and exit trace and for large payloads for apim-v2 pods.

About this task

For apim-v2 pods, the default logging settings do not include entry and exit trace and logging of large payloads.

Logging of large payloads is typically needed if you are logging **apim:webhookPayload** or other processes that log large variables.

You can also set the debug level without needing to restart the pods.

You can enable the settings through either the APIM deployment YAML file, the toolkit, or the REST APIs. Note, you must use the toolkit or REST API to set the debug level without restarting the pods.

Procedure

- Updating the settings in the APIM deployment YAML file
  Note: This action causes a pod restart.
  - The DEBUG variable works the same as prior releases.

    ```
    - env:
        - name: DEBUG
          value:
    audit,bhendi:error,bhendi:probe,bhendi:flags,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:
    *
    ```

    To enable entry and exit trace, add **trace:*** to the start of the debug string:

    ```
    - env:
        - name: DEBUG
          value: trace:*,audit,bhendi:error,bhendi:probe,bhendi:flags,bhendi:webhookAudit,bhendi:cassandra-
    transactions,apim:server,apim:error,apim:routes:*,apim:routesc:*,apim:oidc,apim:oidc:*,apim:taskmanager:info
    ```

- To enable large object logging:

```
- env:
    - name: VELOX_LOG_FULL_PAYLOAD
      value: "true"
```

- Updating the settings by using the toolkit
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  apic log-spec:get
  apic log-spec:update  LOG_SPEC_FILE
  ```

  Where the spec file contains:

  ```
  {"specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error", "large_objects": true}
  ```

- Updating the settings by using the REST API
  Note: This action does not cause a pod restart. Also, this action is for a single APIM pod environment only.

  ```
  GET /cloud/api/log-spec
  PUT /cloud/api/log-spec
  ```

  For example, to set debug level and large objects logging:

  ```
  curl -k https://172.16.140.212:3003/api/cloud/log-spec -X PUT -H "Authorization: Bearer $BEARER"
      -H "Accept: application/json" -d '{"specification":
  "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error","large_objects": true}'
      -H "Content-Type: application/json"
  ```

  The command responds with:

  ```
  {
      "specification": "apim:routes:log_spec,audit,bhendi:error,apim:server,apim:error",
      "large_objects": true,
      "message": "Successfully changed the log specification on all apim-v2 pods. Success on IP(s): 172.16.140.212,
  172.16.140.213"
  }
  ```

  Note: The response might include the following warning, which can be ignored:

  ```
  WARNING: Could not change the log specification on all apim-v2 pods. Success on IP(s): 4.5.6.7  Failed on IP(s): 1.2.3.4
  ```

  To view the REST APIs for logging, go to API Connect REST APIs, and select IBM API Connect Platform - Cloud Management API 2.0.0 reference > Resource: Log Spec.

Troubleshooting

Troubleshoot your deployment on VMware.

Note: In the  Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
See:

- **Recreating a calico pod that is in the CrashLoopBackOff state**
  If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it.
- **Running a filesystem check on a VMware root partition**
  You can run a filesystem check on the appliance root filesystem at boot time.
- **Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment**
  In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.
- **Troubleshooting analytics on VMware**
  If your API Connect analytics subsystem encounters problems, see the analytics troubleshooting topics.

Recreating a calico pod that is in the `CrashLoopBackOff` state

If you complete an upgrade and find that one or more of the calico pods are in the `CrashLoopBackOff` state, you can delete the pod to recreate it.

Complete the following steps:

1. Get the names of the calico pods:

   ```
   kubectl -n kube-system get pods | grep calico
   ```

2. Recreate each pod by deleting it with the following command:

   ```
   kubectl -n kube-system delete pod <calico_pod_name>
   ```

Running a filesystem check on a VMware root partition

You can run a filesystem check on the appliance root filesystem at boot time.

About this task

If the appliance root filesystem is mounted read-only because it is corrupt, use the following steps to run **fsck** on root partition:

Procedure

1. Access to the VMware console for the Appliance, and after causing it to reboot, make sure to bring up a console to the appliance (as needed to give focus to the window by clicking the mouse into it), and press the `Esc` key repeatedly.
   You will see a boot screen similar to the following:

   ```
   GNU GRUB v2.02
   .
   .
   - Ubuntu
   - Advanced options for Ubuntu
   .
   .
   .
   Press Enter to boot the selected OS, 'e' to edit the commands
   before booting or 'c' for a command-line
   ```

2. Press **e** to edit the commands before booting, and add the lines `fsck.mode=force` and `fsck.repair=yes`.
   For example, the boot screen contents resemble:

   ```
   GNU GRUB v2.02
   .
   .
   set params 'Ubuntu'
       fsck.mode=force
       fsck.repair=yes
   .
   .
   .
   Press Ctrl-x or F10 to boot
   .
   ```

3. Press F10 to boot.
4. The following command should show that **fsck** was run recently:

   ```
   root@ip-230:~# sudo tune2fs -l /dev/sda1 | grep "Last checked"
   Last checked:             Wed Jul  1 19:32:25 2020
   ```

Dynamically re-registering and reconfiguring a Gateway service in a VMware deployment

In API Connect, Gateway services do not persist their configuration settings by default. Instead, the master configuration is stored on the Management server and the *Dynamic Reregistration and Reconfiguration* (DRR) mechanism resynchronizes configuration data when needed. The DRR process is used when proper High Availability/Disaster Recovery (HA/DR) is not configured, or if a manual resynchronization is required.

If a Gateway service is not configured properly for resiliency and is restarted, the gateways in the Gateway service will lose the configuration from the Management server. Configuration data from the Management server is maintained on the gateway service according to the gateway peering configuration on the gateways.

Preventing the loss of configuration data

For high availability in production environments, use a minimum of three gateways in the Gateway service. In non-production environments, if a single gateway is used, then availability can be improved by ensuring the persistence setting on the gateway peering configuration is set to `local://` or `RAID`; these settings apply to virtual and physical appliances only.

Forcing re-population of the configuration data

To repopulate the configuration data, complete the steps in the following section to trigger an outage-less DRR.

Triggering an outage-less DRR

To force a Dynamic Reregistration and Reconfiguration across a peer group from within the gateway service without requiring a restart, complete the following steps using the CLI. This process flushes the primary peering object configured for the apic-gw-service. This task can only be performed with CLI, and requires the default admin ID for running the `diag` command.

1. Use `ssh` to connect to gateway service.
2. Switch to the API Connect application:

   ```
   switch <APIC_APP_DOMAIN>
   ```

3. Show the current gateway-peering-status:

   ```
   show gateway-peering-status
   ```

4. If the server to which the ssh connection was made is not primary for the apic-gw-service gateway-peering object, force this server to become primary:

   ```
   config; gateway-peering-switch-primary <gateway-peering-name-for-apic-gw-service>;
   ```

5. Flush the apic-gw-service gateway-peering object:

   ```
   diag; gateway-peering-flush <gateway-peering-name-for-apic-gw-service>; exit
   ```

6. Disable and then re-enable the apic-gw-service object for every member of the gateway service:

   ```
   config; apic-gw-service; admin-state disabled; exit
   apic-gw-service; admin-state enabled; exit; exit
   ```

7. Confirm that the apic-gw-service was flushed and is now waiting for gateway service registration:
   Look in the debug log target for the apic-gw-service, located in logtemp:/// and check for a message similar to the following example:

   ```
   20200618T232339.332Z [0x88e000d7][apic-gw-service][notice]
   apic-gw-service(default): tid(2653): Waiting for gateway service registration.
   ```

   The DRR will be triggered by the next arrival of a webhook event. The Management server sends a heartbeat to the gateway at five-minute intervals, prompting the gateway to check whether it has lost its configuration and if so, trigger a DRR. In addition, if the Management server has previously marked a Catalog or cloud as being unavailable for a particular gateway service, a successful heartbeat triggers synchronization for that Catalog or cloud on that gateway service.

8. (Optional) Force a BAU webhook event to be sent from API Manager to trigger the DRR:
   If you do not want to wait for the Management server to send a heartbeat, you can trigger the DRR manually by completing the following steps:

   a. Open the API Manager.
   b. Open the Catalog.
   c. Click Settings > Edit.
   d. Update the Summary field with some text so that it is modified.
   e. Click Save.

When the event is received, the DRR is initiated.

Troubleshooting analytics on VMware

If your API Connect analytics subsystem encounters problems, see the analytics troubleshooting topics.

For problems with the analytics subsystem, see Troubleshooting analytics.

Migrating v5-compatible APIs to API Gateway

Use the migration utility to automate the migration of v5-compatible APIs to DataPower API Gateway APIs.

About this task

If your deployment includes v5-compatible APIs, they can only be used with the DataPower v5-compatible Gateway (also known as the v5c gateway). To use the v5-compatible APIs with the DataPower API Gateway, you must migrate the APIs to the newer format.

The migration process involves the following tasks:

1. Install and configure the required version of API Connect and migration tools.
2. Plan and test your migration to ensure all tools work as intended.
3. Use the API Connect operations tool (`apicops`) to extract API data from your v10.0.8.0 (or later) deployment.
4. Use the API Connect migration utility (AMU) to unpack the data into YML files for porting to the newer format.
5. Review the unpacked data and port the v5-compatible APIs to the format required by the DataPower API Gateway.
6. Use the AMU to load the ported APIs back into your v10.0.8.0 (or later) deployment.

- **Preparing the environment**
  Install all of the required applications before attempting to migrate v5-compatible APIs to the DataPower API Gateway.
- **Planning your API migration**
  Plan how you will migrate your v5-compatible APIs and then test the process.
- **Downloading and extracting the data to migrate**
  Use `apicops` to download data from API Connect, and then use the AMU to extract the data from the downloaded archive.
- **Converting v5-compatible API definitions**
  To convert v5-compatible APIs to the format required by the DataPower API Gateway, you must map all v5-compatible gateway services to DataPower API Gateway services, optionally specify any configuration settings to be used in the conversion, and use the AMU to port the API definitions.
- **Pushing custom policies and gateway extensions to the DataPower API Gateway**
  Use the AMU to push the Cloud Manager admin organization's data to the Management server, which pushes custom policies and gateway extensions to your DataPower API Gateway Services.
- **Pushing provider organization data**
  Use the AMU to push the provider organization data to the Management server.

Preparing the environment

Install all of the required applications before attempting to migrate v5-compatible APIs to the DataPower API Gateway.

About this task

Migrating v5-compatible APIs to the DataPower API Gateway requires the following applications:

- API Connect v10.0.8.0 or later
- API Connect operations (**apicops**) tool, latest v10 release
- API Connect migration utility (AMU), release v10.0.8.0-R0 or later
- Node version 20.15.1 or later

Complete the following steps to set up your environment with the required applications:

Procedure

1. Upgrade to API Connect v10.0.8.0 or later.
   Your API Connect deployment must be at 10.0.8.0 or later. Refer to the upgrade instructions in the Installing and maintaining IBM API Connect section.
2. Download and configure the latest release of the **apicops** tool.
   Download the **apicops** binary for your operating system from GitHub at latest release and rename the file to apicops.

   Review the associated README for requirements and instructions for using the tool.
3. Download the migration utility v10.0.8.0-R0 or later.
   The API Connect migration utility (AMU) is available from IBM Fix Central. On Fix Central, set the Installed version to 10.0.8.0 or later, and search for the text "migration" to locate the AMU.
4. Install Node version 20.15.1 or later.

What to do next

After you have installed the required applications for your environment, complete the following tasks to migrate your v5c-compatible APIs.

Planning your API migration

Plan how you will migrate your v5-compatible APIs and then test the process.

About this task

Plan the migration process, migrate a small set of APIs, and then test the results. You can refine settings and repeat the process as needed.

Procedure

1. Review all of the migration topics to ensure you understand the requirements, the general process, and important considerations.
2. Plan how you will migrate your v5-compatible APIs to the DataPower Gateway.
   Make sure you know exactly which APIs you want to migrate, and in which provider organizations and catalogs they are stored.
3. Migrate a proof-of-concept deployment.
   Migrate 10 to 20 of your most commonly used v5-compatible APIs to ensure that your migration tools are configured correctly and the migration process works as intended. Plan to run several test iterations of migration.

   You can use the migration utility's **--dry-run** option to perform iterations of the migration push without actually uploading data to API Connect. The test runs offer an opportunity to test for errors and warnings that need to be resolved before you perform the actual data push.

   You can use the migration utility's **--move-subscriptions** parameter to move subscriptions during the push operation that uploads converted data back into API Connect.
4. Test the APIs that you migrated as proof-of-concept.
   Testing the migrated APIs helps you to determine which migration utility settings you need for successfully converting the v5-compatible APIs to DataPower API Gateway. If needed, you can move or delete the results, modify the configuration settings, and run the migration again. When you rerun the migration **port** command using the same target folder for output, the utility skips artifacts that have already been converted to DataPower API Gateway.

Downloading and extracting the data to migrate

Use **apicops** to download data from API Connect, and then use the AMU to extract the data from the downloaded archive.

Procedure

1. Use **apicops** to extract and download data from API Connect as a .pgdmp archive file.
   Run the following command:

   ```
   apicops postgres:pg_dump -e <archive_name>.pgdmp
   ```

   where ***<archive_name>*.pgdmp** is a name that you create for the archive file that will contain the downloaded data; for example, v10_backup.pgdmp.
2. Copy the .pgdmp archive file to the location where you installed the AMU, storing it in the same directory as the AMU.

3. Use the AMU to unpack the archive stored in the .pgdmp archive file.
   Run the following command in the same directory where you stored the downloaded .pgdmp archive file (see Table 1 for available the parameters):

   On Windows: open a command window with Administrator privileges, and omit the "./" from the command.

   ```
   ./apicm archive:unpack-v10 <archive_name>.pgdmp
   ```

   The first time you use the AMU, you are prompted to accept the license. You must accept the license to continue.

   Table 1. AMU `archive:unpack-v10` parameters

Parameter	Description
<archive_name> .pgdmp	Required. The .pgdmp archive file created containing the data downloaded from API Connect.
`--provider-orgs`	Optional. A comma-separated list containing one or more provider organization names. Use this parameter to unpack only the data for the specified provider organizations instead of unpacking the entire archive. Example: `./apicm archive:unpack-v10 <archive_name>.pgdmp --provider-orgs=<pOrg1_name>,<pOrg2_name>,<pOrg3_name>`

   When the command completes, the data is unpacked to the /cloud-v10 directory, which is located in the same directory as the AMU, and is populated with YAML files representing the configuration objects in the .pgdmp file.

   Important: The unpack directory must be named /cloud-v10. Do not rename the directory.

Converting v5-compatible API definitions

To convert v5-compatible APIs to the format required by the DataPower API Gateway, you must map all v5-compatible gateway services to DataPower API Gateway services, optionally specify any configuration settings to be used in the conversion, and use the AMU to port the API definitions.

Procedure

1. Map your v5-compatible Gateway Services to DataPower API Gateway services.
   You must map your v5-compatible Gateway Services (the v5c gateway) to DataPower API Gateway services so that the AMU command has a target for migrating custom policies and gateway extensions, and can migrate the configured gateway services for each catalog and space.

   a. In the unpacked data, locate the gateway services.
      Each of the gateway services in stored in cloud-v10/admin-org/availability-zones/*<az_name>*/gateway-services/.

   b. For each v5-compatible gateway service, create a mapping.yml file that contains the name of the DataPower API Gateway Service you want to map to.
      Create the mapping.yml file directly in the directory containing the v5-compatible gateway service. The file must contain 3 statements:
      - The artifact type, which is always `gateway-service:`
      - The name of the DataPower API Gateway service (not the Title or ID)
      - The gateway type for that gateway service, which is always `datapower-api-gateway` for converting to DataPower API Gateway service

      For example, the following mapping.yml file maps the v5-compatible gateway service to the DataPower API Gateway service named "gateway-10-1" and specifies a target gateway of type `datapower-api-gateway`:

      ```
      gateway-service:
        name: gateway-10-1
        gateway-type: datapower-api-gateway
      ```

      If you have several v5-compatible gateway services and you want to map each of them to the same DataPower API Gateway service, copy the mapping.yml file into the directory for each of those v5-compatible gateway services.

      Important: If you are running on API Connect 10.0.8.1 the **Enable AI Gateway** field needs to be set to **false** for any DataPower API Gateway services. If it is set to true the AMU will not be able to push policy information to the DataPower API Gateway service.
      Make sure to map all of the v5-compatible gateway services to DataPower API Gateway services before attempting to port the APIs in the next step.

2. Optional: Create a configuration file that defines settings for migrating the v5-compatible APIs.
   In the directory where the AMU is stored, create a file called `config.yml` and use it to specify configuration settings (see Table 1 for the configuration settings).

   Example `config.yml` file:

   ```
   custom-policies-scope: global
   emulate-v4-plan-rate-limit: false
   deploy-policies:
     - proxy_1.5.0
     - redact_1.5.0
     - invoke_1.5.0
     - gatewayscript_1.0.0
   rewrite-apis:
     enable-api-logging: false
     proxy-policy: proxy_1.5.0
     redact-policy: redact_1.5.0
     invoke-policy: invoke_1.5.0
     xslt-policy: xslt_2.0.0
     gatewayscript-policy: gatewayscript_1.0.0
     if-policy: switch_2.0.0
     switch-policy: switch_2.0.0
     optimize-gws: false
     no-retitle: true
   ```

   If you omit the config.yml file, you can optionally specify configuration settings as parameters on the command line when you port the APIs in the next step.

   Table 1. Migration configuration settings

Parameter	Valid values	DataPower version required	Description
`activity-log-policy`	`activity-log_1.5.0`, `set-variable_2.0.0`	DP 10.0.4.0+	Defines how to process the v5 activity-log policy when the migration utility rewrites the API assembly. The default value is `activity-log_1.5.0`, which changes the activity-log version to 1.5.0. When set to `set-variable_2.0.0`, the migration utility sets context variables based upon the value of the activity-log content and error-content configuration values.
`chunked-uploads`	`true / false` The default value is `false`.	For `invoke_1.5.0`: 10.0.1.1+, 10.0.2.0+ For `invoke_2.0.0`: 10.0.0.0+	If an `invoke_1.5.0` or `proxy_1.5.0` policy exists in an assembly in the API, then set `chunked-uploads` to `true` to enable chunked encoding for HTTP 1.1 requests to the target server. If an `invoke_2.0.0` policy exists in an assembly after the migration, then set `chunked-uploads` to `false` explicitly for the policy, as the default value for `chunked-uploads` in API Gateway is `true`.

`client-id-header-override`	String. The string cannot contain spaces. Follow the guidelines for `apiKey name:`. No default value.	10.0.0.0+	Override the existing `X-IBM-Client_Id` name value with the new value. In API Gateway, `x-key-type` makes it possible to define custom naming for `client_id` and `client_secret`.
			
			Example:
			
			`--client-id-header-override="acme-foo"`
			
			In this example, the `securityDefinitions` property is changed from:
			
			`foo:`
			`  type: apiKey`
			`  name: X-IBM-Client-Id`
			`  in: header`
			
			to the following:
			
			`foo:`
			`  type: apiKey`
			`  name: acme-foo`
			`  in: header`
			`  x-key-type: client_id`
			
			Calls to this API must supply `acme-foo: <client-id>` in the request header instead of the original `X-IBM-Client-Id: <client-id>`.

`client-id-query-override`	String. The string cannot contain spaces. Follow the guidelines for `apiKey name:`. No default value.	10.0.0.0+	Override the existing `client_id` name value with the new value. In API Gateway, `x-key-type` makes it possible to define custom naming for `client_id` and `client_secret`.
			
			Example:
			
			`--client-id-query-override="acme-foo"`
			
			In this example, the `securityDefinitions` property is changed from:
			
			`foo:`
			`  type: apiKey`
			`  name: client_id`
			`  in: query`
			
			to the following:
			
			`foo:`
			`  type: apiKey`
			`  name: acme-foo`
			`  in: query`
			`  x-key-type: client_id`
			
			Calls to this API must supply `?acme-foo=<client-id>` in the query parameter instead of the original `?client_id=<client-id>`.

`client-secret-header-override`	String. The string cannot contain spaces. Follow the guidelines for `apiKey name:`. No default value.	10.0.0.0+	Override the existing `X-IBM-Client-Secret` name value with the new value. In API Gateway, `x-key-type` makes it possible to define custom naming for `client_id` and `client_secret`.
			
			Example:
			
			`--client-secret-header-override="acme-foo"`
			
			In this example, the `securityDefinitions` property is changed from:
			
			`foo:`
			`  type: apiKey`
			`  name: X-IBM-Client-Secret`
			`  in: header`
			
			to the following:
			
			`foo:`
			`  type: apiKey`
			`  name: acme-foo`
			`  in: header`
			`  x-key-type: client_secret`
			
			Calls to this API must supply `acme-foo: <client-secret>` in the request header instead of the original `X-IBM-Client-Secret: <client-secret>`.

Parameter	Valid values	DataPower version required	Description
client-secret-query-override	String. The string cannot contain spaces. Follow the guidelines for **apiKey name:**. No default value.	10.0.0.0+	Override the existing **client_secret** name value with the new value. In API Gateway, **x-key-type** makes it possible to define custom naming for **client_id** and **client_secret**. Example: **--client-secret-query-override="acme-foo"** In this example, the **securityDefinitions** property is changed from: **foo:** **type: apiKey** **name: client_secret** **in: query** to the following: **foo:** **type: apiKey** **name: acme-foo** **in: query** **x-key-type: client_secret** Calls to this API must supply **?acme-foo=<client-secret>** in the query parameter instead of the original **?client_secret=<client-secret>**.
copy-id-headers-to-message	**true / false** The default value is **false**.	10.0.1.1+, 10.0.2.0+	When set to **true**, the **client-id** header is copied from **request.headers** to **message.headers** to be passed to the backend server. Set this parameter to **true** if your invoke backend services expect the **client-id** to be passed through.
custom-policies-scope	**catalog / global** The default value is **catalog**.	10.0.0.0+	When set to **catalog**, the original v5 or v5-compatible catalog that contains the custom policy is staged for pushing to the target catalog and organization in API Gateway. When set to **global**, the custom policy is staged for pushing to API Gateway and is visible to all organizations and catalogs within that gateway. **archive:port-to-apigw-v10** sets up the custom policies for pushing to API Gateway, but does not do the pushing. If **global** scope is used, **archive:push-v10** of the admin organization will push all custom policies associated with the configured gateways. If **catalog** scope is used, then the **archive:push-v10** of the admin organization will initialize the custom policies on the gateway. A subsequent **archive:push-v10** of the provider organization is needed to advertise the custom policies in the catalogs contained within the provider organization. Note: Potential conflicts between custom policies of the same name and version are resolved according to the following rules: • When set to **global** and two policies under the same gateway service have the same name, version, and md5 hash value, then the duplicates are discarded and a message is generated. • When set to **global** and two policies under the same gateway service have the same name, version, and a differing md5 hash value, then global scope cannot be applied. Catalog scope is used and a warning is generated. • When set to **catalog**, **<orgname>_<catname>_** is appended to the zip filename to maintain uniqueness.
deploy-policies	Any combination of the following values: **gatewayscript_1.0.0,if_1.5.0, invoke_1.5.0, proxy_1.5.0,redact_1.5.0, switch_1.5.0, validate-usernametoken_1.0.0, xslt_1.0.0** The default values are: **if_1.5.0, invoke_1.5.0, proxy_1.5.0, redact_1.5.0, switch_1.5.0, validate-usernametoken_1.0.0, xslt_1.0.0**	For **invoke_1.5.0**, **proxy_1.5.0**, **gatewayscript_1.0.0**, and **xslt_1.0.0**: 10.0.0.0+ For **if_1.5.0** and **switch_1.5.0**: 10.0.1.1+, 10.0.2.0+ For **redact_1.5.0**: 10.0.3.0+ For **validate-usernametoken_1.0.0**: 10.0.1.3+, 10.0.2.0+	Defines which backwards-compatible policies should be advertised by DataPower to API Manager. Note: Any legacy policies that are specified in the **config.yml** file or by using the **apicm** command must also be specified by using **deploy-policies**. If these policies are not specified by using **deploy-policies**, an error is returned.
emulate-v4-plan-rate-limit	**true / false** The default value is **false**.	10.0.1.2+, 10.0.2.0+	Determines whether all APIs emulate the v4 plan rate limit. If set to **true**, then API operations do not share the rate limit. This setting matches the behavior of the **x-ibm-gateway-emulate-v4-plan-rate-limit** v5 option.
enable-api-logging	**true / false** The default value is **true**.	10.0.0.0+	Log all changes that the migration utility makes when rewriting APIs. These changes are logged as comments in the API YAML file.
enforce-required-params	**true / false** The default value is **false**.	10.0.1.1+, 10.0.2.0+	When set to **true**, required parameters are enforced, which is the default behavior in API Gateway. When set to **false**, required parameters are not enforced, even if the required parameter checkbox selected.

Parameter	Valid values	DataPower version required	Description
gatewayscript-policy	One of the following values: **gatewayscript_1.0.0**, **gatewayscript_2.0.0** The default value is **gatewayscript_2.0.0**.	10.0.0.0+	Defines which gatewayScript policy the migration utility uses when rewriting the API assembly. **gatewayscript_1.0.0**: A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use **gatewayscript_1.0.0** if the gatewayScript policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings. **gatewayscript_2.0.0**: The migration utility rewrites the existing API to gatewayScript 2.0.0. This policy supports the **header-metadata** module for compatibility with the v5-compatible gateway. Specifying **gatewayscript_2.0.0** can cause migration errors or run-time errors. Use **gatewayscript_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
if-policy	One of the following values: **if_1.5.0**, **switch_2.0.0** The default value is **if_1.5.0**.	For **if_1.5.0**: 10.0.1.1+, 10.0.2.0+ For **switch_2.0.0**: 10.0.0.0+	Defines which **if** policy the migration utility uses when rewriting the API assembly. **if_1.5.0**: The migration utility rewrites the existing API to if 1.5.0. **switch_2.0.0**: The migration utility rewrites the existing API to switch 2.0.0. Specifying **switch_2.0.0** can cause migration errors or run-time errors. Use **switch_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
invoke-policy	One of the following values: **invoke_1.5.0**, **invoke_2.0.0** The default value is **invoke_1.5.0**.	10.0.0.0+	Defines which invoke policy the migration utility uses when rewriting the API assembly. **invoke_1.5.0**: The migration utility rewrites the existing API to invoke 1.5.0. **invoke_2.0.0**: The migration utility rewrites the existing API to invoke 2.0.0. Specifying **invoke_2.0.0** can cause migration errors or run-time errors. Use **invoke_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
no-retitle	**true / false** The default value is **false**.	10.0.0.0+	Defines whether to append the porting suffix to the **title** of the migrated API, product, or OAuth provider. Set this option to **true** if you want the **title** of the migrated API, product, or OAuth provider to match the original **title** in the v5-compatible YAML file.
optimize-gws	**true / false** The default value is **false**.	10.0.0.0+	When set to **true**, gatewayScript policies are modified to map v5 functions to API Gateway functions. Setting **optimize-gws** to **true** is valid only for the **gatewayscript_2.0.0** policy. If it is set to **true** for gatewayscript_1.0.0, an error is generated. Note: Setting **optimize-gws** to **true** can result in performance enhancements. However, the modifications to gatewayScript policies by the migration utility can cause problems. When using this setting, review all gatewayScript policy modifications after migration.
porting-suffix	A string containing alphanumeric, dash, underscore and dot characters. The default value is **-apigw**.	10.0.0.0+	Defines the suffix to be used when renaming APIs, Products, OAuth Providers, and other ported artifacts. The suffix is appended to the version on APIs, Products and other ported artifacts that have versions, and onto the name for OAuth Providers and other ported artifacts that do not have versions. If **porting-suffix** is not specified then a value of **-apigw** will be used. The porting suffix can contain alphanumeric, dash, underscore and dot characters. Prior to AMU 10.0.5.4 the porting suffix could not be overridden and **-apigw** was appended to the name for all ported artifacts.
proxy-policy	One of the following values: **proxy_1.5.0**, **invoke_2.0.0** The default value is **proxy_1.5.0**.	10.0.0.0+	Defines which proxy policy the migration utility uses when rewriting the API assembly. **proxy_1.5.0**: The migration utility rewrites the existing API to **proxy 1.5.0**. **invoke_2.0.0**: The migration utility converts the proxy policy to invoke 2.0.0. Specifying **invoke_2.0.0** can cause migration errors or run-time errors. Use **invoke_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
redact-policy	One of the following values: **redact_1.5.0**, **redact_2.0.0** The default value is **redact_1.5.0**.	10.0.3.0+	Defines which redact policy the migration utility uses when rewriting the API assembly. **redact_1.5.0**: The migration utility rewrites the existing API to **redact 1.5.0**. **redact_2.0.0**: The migration utility rewrites the existing API to **redact 2.0.0**. Specifying **redact_2.0.0** can cause migration errors or run-time errors, including changes to what is redacted, particularly with redactions meant for JSON payloads. Use **redact_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file. Note: Starting in v10.0.8.1 we will no longer allow **redact_2.0.0** and the only allowable value will be **redact 1.5.0**.
repair-wsdl-apis	**true / false** The default value is **true**.	10.0.1.1+, 10.0.2.0+	If an API ported from V5 is created from WSDL, the WSDL is read and checked for accuracy. If **repair-wsdl-apis** is set to **true**, then the API and WSDL are automatically repaired. For example, if the WSDL ZIP file contains unnecessary files, they are automatically removed if **repair-wsdl-apis** is **true**.
return-v5-responses	**true / false** The default value is **false**.	10.0.1.1+, 10.0.2.0+	When set to **true**, OAuth-related messages are printed in the v5 response format. When set to **false**, OAuth-related response messages are printed in API Gateway response format.

Parameter	Valid values	DataPower version required	Description
`switch-policy`	`switch_1.5.0`, `switch_2.0.0` The default value is `switch_1.5.0`.	For `switch_1.5.0`: 10.0.1.1+, 10.0.2.0+ For `switch_2.0.0`: 10.0.0.0+	Defines which switch policy the migration utility uses when rewriting the API assembly. `switch_1.5.0`: The migration utility rewrites the existing API to switch 1.5.0. `switch_2.0.0`: The migration utility rewrites the existing API to switch 2.0.0. Specifying `switch_2.0.0` can cause migration errors or run-time errors. Use `switch_2.0.0` if you are able to review and verify all changes made by the migration utility in the API YAML file.
`use-config-file`	`true / false` The default value is `false`.	10.0.0.0+	Use the `config.yml` file that is in the same directory as the `apicm` binary file that is being executed. If this file is used, configuration options cannot be set using the command line. The purpose of the config file is to specify the command inputs given on this page, but in an easy-to-read file format (YAML).
`v5-request-headers`	`true / false` The default value is `true`.	10.0.1.2+, 10.0.2.0+	When set to `true`, the following v5-compatible request headers are set: `Via`, `X-Global-Transaction-ID`, `X-Client-IP`. When set to `false`, these request headers are not set.
`validate-usernametoken-policy`	`validate-usernametoken_1.0.0` The default value is empty.	10.0.1.3+, 10.0.2.0+	Defines whether or not to use the `validate-usernametoken` v5 emulation policy when the migration utility rewrites the API assembly. When empty, the migration utility takes no action on the policy.
`xslt-policy`	One of the following values: `xslt_1.0.0`, `xslt_2.0.0` The default value is `xslt_1.0.0`.	10.0.0.0+	Defines which gatewayscript policy the migration utility uses when rewriting the API assembly. `xslt_1.0.0`: A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use `xslt_1.0.0` if the xslt policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings. `xslt_2.0.0`: The migration utility rewrites the existing API to xslt 2.0.0. Specifying `xslt_2.0.0` can cause migration errors or run-time errors. Use `xslt_2.0.0` if you are able to review and verify all changes made by the migration utility in the API YAML file.

3. Use the AMU `port` command to convert the v5-compatible APIs to the DataPower API Gateway format.
   When you run the `port` command with the AMU, there are 3 options for specifying configuration settings for your APIs:

   - Store the settings in the config.yml migration configuration file.
     You must name the configuration file config.yml. Specify the `--use-config-file=true` parameter on the command line when you port the APIs.
   - Include the configuration settings on the command line (see Table 2 for the configuration settings).
     Specify the settings as parameters on the command line. If you also specify a configuration file, any configuration settings specified as parameters directly on the command line are ignored.
   - Accept the default configuration settings.
     If you don't specify a configuration file and also don't specify any configuration parameters on the command line, the AMU uses the default configuration when porting the APIs.

   To port the APIs, run the following command:

   On Windows: open a command window with Administrator privileges, and omit the "./" from the command.

   ```
   ./apicm archive:port-to-apigw-v10 <path_to_APIs> --enable-api-logging=false --use-config-file=true
   ```

   where `<path_to_APIs>` represents one of the following locations:
   - The top-level /cloud-v10 directory containing all of the extracted archive:
     The AMU ports all artifacts within the directory, including APIs, Products, OAuth providers, and custom policies. Running a subsequent `archive:push-v10` command pushes all of the converted artifacts to the DataPower API Gateway. Custom policies and OAuth providers are not migrated if a directory other than /cloud-v10 is specified.
     Attention: Running the `port` command on any subdirectory within the unpacked /cloud-v10 directory could leave the directory in an inconsistent state, and cause the subsequent `archive:push-v10` command to fail.
   - A single API file, or a directory that contains only APIs or Products:
     When you are testing your migration settings, you might want to convert just a few APIs or Products to verify the settings. When you use this approach, you cannot use the high-level `archive:push-v10` command to push the artifacts to the DataPower API Gateway. Instead, you must push the ported artifacts into API Manager using either the toolkit or the user interface.

     When testing is complete, you can delete the artifacts from testing and run the `port` command on the top-level /cloud-v10 directory to convert all of the artifacts in one operation, and then use the `archive:push-v10` command to push them all to the DataPower API Gateway in a second operation.

Table 2. Parameters for the `port` command

Parameter	Description
`--enable-api-logging=false`	Optional. Disable logging. By default, logging is enabled for the conversion and all changes that the migration utility makes when rewriting APIs are logged as comments within the API's YAML file.
`--use-config-file=true`	Optional. When converting APIs, apply the configuration settings specified in the config.yml file that is stored in the same directory as the AMU.
Parameters from Table 1, Migration configuration settings.	Optional. Follow the format shown in Table 1, and prefix each parameter with the -- symbol and leave a blank space before the next parameter as shown in the example command.

4. Review the ported artifacts.
   The API conversion process annotates the YAML file and logs with information regarding the artifacts that it attempts to convert. For cases where additional information is available or further action is required, the YAML input file and logs contain links to documentation.

   Review the entire draft output YAML file for conformance, performance, and errors. Review the log files for messages about any manual actions that might be needed. For more information, see Reviewing APIs converted to DataPower API Gateway. By default, all changes that the migration utility makes when rewriting APIs are logged as common.

Because of differences between the programming models of v5-compatible APIs and DataPower API Gateway APIs, the command might not be able to convert all items; you might need to manually convert the failed items. In these cases, messages generated by the **apicm archive:port-to-apigw-v10** command provide links to documentation that provides more details about changes you must make for the items to be compatible with DataPower API Gateway.

- **Reviewing APIs converted to DataPower API Gateway**
  The migration utility **apicm archive:port-to-apigw** and **apicm archive:port-to-apigw-v10** commands, which assists in the conversion of v5 APIs for use with the v10 DataPower® API Gateway, provides draft output YAML files containing the results of the conversion process.
- **Messages generated during conversion of APIs to DataPower API Gateway**
  Reference information about the messages generated by the migration utility commands **apicm archive:port-to-apigw** and **apicm archive:port-to-apigw-v10**.
- **Parse actions added to the API assembly after migration**
  The migration utility **apicm archive:port-to-apigw** and **apicm archive:port-to-apigw-v10** commands add parse actions to the API assembly depending on the policies specified in your migration configuration.
- **Fine-tuning APIs after migration**
  After running the migration utility **apicm archive:port-to-apigw** or **apicm archive:port-to-apigw-v10** command, review the converted APIs to determine if any of the changes made by the migration utility can be modified to enhance performance and usability.

Reviewing APIs converted to DataPower API Gateway

The migration utility **apicm archive:port-to-apigw** and **apicm archive:port-to-apigw-v10** commands, which assists in the conversion of v5 APIs for use with the v10 DataPower® API Gateway, provides draft output YAML files containing the results of the conversion process.

Procedure

1. Review the entire output YAML files for conformance, performance, and errors.
   The conversion process annotates the YAML file and logs with information regarding the artifacts that are converted. For cases where additional information is available or further action is required, the YAML file and logs contain links to documentation.
2. Make any necessary changes to port APIs to DataPower API Gateway.

Activity log messages

- ACT06
- ACT07
- ACT09

ACT06 `activity-log` policy set to `activity-log_1.5.0`, converting `activity-log` to `activity-log_1.5.0`.

Explanation

See message text.

Severity

info

ACT07 `activity-log` policy set to `set-variable_2.0.0`, converting `activity-log` to `set-variable_2.0.0`.

Explanation

The `activity-log` success and error values are saved into context variables. A subsequent log policy will reference these variables, which will generate the analytics log data based upon the desired log level.

Severity

info

ACT09 For `activity-log` policy set to `set-variable_2.0.0`, added a `switch` policy with `log` policies into the API finally clause to utilize the `activity-log` variables that were set.

Explanation

A `switch` policy determines if the analytics log level should be based upon the success of the API or on error `activity-log` settings. The context variable set in a prior `set-variable` policy is used as the `log` policy log level to gather the appropriate level of data in the analytics log.

API01 The specified API YAML input file is of gateway type `datapower-api-gateway`. This utility accepts only v5-compatible APIs of gateway type `datapower-gateway`.

Explanation

The input API YAML file must be of gateway type **`datapower-gateway`**. If the gateway type is **`datapower-api-gateway`**, the API does not need to be converted. Any other gateway type is not supported.

Response

Review your input file to confirm that it is v5 compatible.

Severity

error

API02 Input API policy is already version 2.0.0. This version is reserved for API Gateway policies only. Skipping conversion of this policy.

Explanation

The input API YAML file must be of gateway type **`datapower-gateway`**. Every policy within that API must be version 1.0.0. Version 2.0.0 policies are reserved for the API Gateway, which should be included only in APIs with gateway type **`datapower-api-gateway`**. No conversion is performed for this policy.

Severity

error

API04 Added missing `/` to the front of the basepath.

Explanation

A v5 API with a **`basepath`** property value that does not start with a **`/`** will have the character **`/`** added at the beginning of the **`basepath`** property of the API Gateway.

Severity

info

API05 Trailing slashes (`/`) removed from the basepath to conform to the API Gateway specification.

Explanation

A v5 API with a **`basepath`** property value that is not a **`/`** but ends with the **`/`** character will have the ending **`/`** character removed in the **`basepath`** property of the API Gateway.

Response

Calls to the API might need to be updated to conform to the new basepath.

Severity

warn

API06 Changed gateway type to `datapower-api-gateway`.

Explanation

See message text.

Severity

info

API07 Moved `assembly request` into `assembly execute`.

Explanation

Older v5 APIs might include the **execute** property within an assembly **request** property. This **execute** property is moved to the API Gateway **assembly**` property.

Severity

info

API08 Moved `assembly implementation` into `assembly execute`.

Explanation

Older v5 APIs might include the **execute** property within an assembly **implementation** property. This **execute** property is moved to the API Gateway **assembly** property.

Severity

info

API09 Moved `assembly response` into `assembly execute`.

Explanation

Older v5 APIs might have the **execute** property within an assembly **response** property. This **execute** property is moved to the API Gateway **assembly** property.

Severity

info

API10 Removed `x-ibm-gateway-invoke-v4-nomap-emulation` API property and replaced it with a `gatewayscript` policy to conform to the API Gateway specification.

Explanation

This v5 API property applies only to the **invoke** policy. In API Gateway, this property has been replaced by a **gatewayscript** policy that will modify the **invoke** policy response in a similar fashion.

Severity

warn

API11 The API property `x-ibm-gateway-sourcecode-resolve-apic-variables` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

This v5 API property is not supported by the API gateway and has been removed. If the **x-ibm-gateway-map-resolve-apic-variables** property is not set, then the original value of this property will be set into the map option **mapResolveApicVariables** automatically.

Severity

error

API12 The API property `x-ibm-gateway-reencode-request-params-slash` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

This v5 API property only applies to the **invoke** and **proxy** policies. In the API Gateway, the functionality of this property has been implemented as an option in the **invoke** policy.
This change was made for the following reasons.

- The option is now clearly visible in the **invoke** policy, making it easy to identify available options.
- Each use of the **invoke** policy can now have a different setting.

Severity

error

API13 The API property `x-ibm-gateway-framework-legacy-json-encoding` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

This v5 API property is not supported by the API gateway and has been removed. If the value of the **`x-ibm-gateway-framework-legacy-json-encoding`** property is present, it will be used by the migration utility when migrating xslt, gatewayscript, and map policy source code to produce the same result as v5 would have produced based upon the property value.

Severity

error

API14 Converted v5-compatible policies to the API Gateway and updated policy versions to 2.0.0.

Explanation

See message text.

Severity

info

API15 The `x-ibm-gateway-api-enforce-response-limits` API property is enabled. Appended `parse` policy to the end of the assembly to parse the JSON response.

Explanation

The v5 API property **`x-ibm-gateway-api-enforce-response-limits`** ensures that a JSON response payload is within the defined JSON parser limits. This functionality is emulated in API Gateway by adding a **`parse`** policy at the end of the assembly.

Severity

info

API16 Removed the `x-ibm-gateway-api-enforce-response-limits` API property and replaced it with a `parse` policy to conform to the API Gateway specification.

Explanation

The v5 API property **`x-ibm-gateway-api-enforce-response-limits`** ensures that a JSON response payload is within the defined JSON parser limits. This functionality is emulated in API Gateway by replacing it with a **`parse`** policy.

Severity

info

API17 Setting `x-ibm-soap` to `%s`.

Explanation

The v5 API path does not have a **`x-ibm-soap`** property with a **`soap-action`** child property, but the schema referenced by this path is for a SOAP document. The **`x-ibm-soap`** property is added with a child property of **`soap-action`** into this path of the APIgateway. The **`soap-action`** property will be determined from the schema encountered.

Severity

info

API18 This `set-variable` policy is used to add the client identification header to the message headers for use by a subsequent `invoke` policy.

Explanation

Typically, the client identification header as defined by the security definition is **`X-IBM-Client-Id`**. This header will be removed from the message headers at the start of the API. A **`set-variable`** policy will add this header back into the message headers, as the v5 API specifies not to suppress this header from being sent by subsequent **`invoke`** policies.

Severity

info

API19 Skipping appending of a `parse` policy for the `x-ibm-gateway-api-enforce-response-limits` API property, as this `parse` policy already exists at the end of the assembly and contains the same `input` and `output` values.

Explanation

See message text.

Severity

info

API20 Added `parse` policy to the beginning of the assembly to parse incoming data.

Explanation

The v5-compatible implementation implicitly parses messages. However, by requiring explicit parsing for every assembly wherever parsing is required, the API Gateway provides greater control over when and how parsing is performed.
The **parse** policy is added in API Gateway for the following purposes.

- To explicitly control when parsing occurs.
- To determine which threat protection settings to apply to a parse.
- To determine which kinds of output to allow.
- To determine how to gather metadata from the parse.

By separating the parsing time from the processing time of the assembly, explicit parsing can also enhance performance.

API Gateway has no implicit parsing. The assembly must explicitly parse when parsing is desired, which ensures that the correct limits and input checks are done.

Response

You should retain the added **parse** policy for any of the following reasons.

- You need non-well-formed XML or JSON documents to abort and call the **catch**.
- The data is still streaming and you need to keep a copy of the data for various reasons.
- You need to use the payload data with another policy.

If you do not need the **parse** policy, remove it. If you retain the **parse** policy, consider the following questions.

- Which threat protection settings do you want to enforce with this **parse** policy?
- Does the use of this **parse** policy remove the need for an additional **parse** policy?
- Do you want to use the metadata from the parse, such as document size and complexity?

Severity

info

API21 Moved catalog specific `x-ibm-gateway-*` API Property: `%s` under catalog: `%s` to API level for further processing.

Explanation

x-ibm-gateway catalog-level properties are not supported in API Gateway. The properties have been moved to the top-level properties section in the API for further processing by the migration utility.

Severity

info

API22 Skipped adding `parse` policy since an adjacent parse of the same properties was already added.

Explanation

The **invoke** policy might add a **parse** policy next to it in the assembly. If this **parse** policy is detected, another parse is not added because it would result in duplicate parses in the assembly. This prevention of duplicate parses applies only if both parses are found to have the same properties.

Severity

info

API23 Removed redundant `parse` policy from end of the assembly.

Explanation

The tool added a duplicate **parse** policy to the end of the assembly. The duplicate policy has been removed as it performs the same action as another **parse** policy in the assembly.

Severity

info

API24 Removed redundant `parse` policy from the beginning of the assembly.

Explanation

The tool added a duplicate **parse** policy to the beginning of the assembly. The duplicate policy has been removed as it performs the same action as another **parse** policy in the assembly.

Severity

info

API25 Removed unsupported `name` property from the Swagger info property.

Explanation

An empty **name** property under the **info** property is not supported in API Gateway. If an API is published with an empty **name** property, an error is generated. Therefore, the migration utility removes the empty **name** property if it is found.

Severity

info

API26 Removed empty `description` property from the Swagger info property.

Explanation

An empty **description** property is not supported in API Gateway. If an API is published with an empty **description** property, an error is generated. Therefore, the migration utility removes the empty **description** property if it is found.

Severity

info

API27 Removed empty `security` property from the Swagger file.

Explanation

An empty object **security** property is not supported in API Gateway. If an API is published with an empty object **security** property, an error is generated. Therefore, the migration utility removes the empty object **security** property if it is found.

Severity

info

API28 Moved `%s` from API properties to this policy option `%s` and set to [%s].

Explanation

In the API Gateway, the functionality of this property has been implemented as a policy option.

Severity

info

API29 Preserved API Property `%s` in YAML.

Explanation

The API property was preserved because there is a 1.0.0 or 1.5.0 policy that requires it.

Severity

info

API30 Removed API Property `%s` from YAML.

Explanation

This property is obsolete and has been removed from the YAML file.

Severity

info

API31 The API property `x-ibm-gateway-custom-policy-with-gws-action` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

In v10, this property is not required to control the behavior of a custom policy that includes a GatewayScript action, as both **true** and **false** scenarios are handled as expected.

Severity

error

API32 The `$ref %s` was not found in the swagger.

Explanation

A **$ref** could not be dereferenced because the reference content was not found in the v5 YAML.

Response

Review the v5 file to confirm that the `$ref` references are valid and exist in the YAML.

Severity

warn

API33 Found usage of inline parameters: `%s` in `%s` policy.

Explanation

API Gateway does not support inline parameters in the Gatewayscript 2.0.0 or XSLT 2.0.0 policies.

Response

Modify the policy to use context variables instead of inline parameters. The following tables show examples of inline parameters in v5 and how they can be rewritten to use context variables in API Gateway.

Table 1. GatewayScript 2.0.0 examples

v5	API Gateway
If `test.data` is a variable: `$(test.data)`	`context.get('test.data');`
If `test.body` is a message: `$(test.body)`	`context.getMessage('test').body;`
`{test.example}`	`context.get('request.parameters.test.example')`

For more GatewayScript 2.0.0 examples, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Table 2. XSLT 2.0.0 example

v5	API Gateway
`$(request.parameters.example)`	`apigw:get-variable('request.parameters.example')` Note: Be sure to use the `apigw` namespace.
`{example}`	`apigw:get-variable('request.parameters.example')`

For more XSLT 2.0.0 examples, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Severity

error

API34 Found `x-ibm-gateway-*` catalog specific property: `%s` under catalog section: `%s`, within an unpublished API.

Explanation

The API was most likely found under the drafts folder of an organization. Because it is not published to a specific catalog, the migration utility cannot determine which API to apply the properties to.

Response

Apply the `x-ibm-gateway-*` properties to the policies of the assembly manually before publishing.

Severity

info

API35 Found `x-ibm-gateway-*` catalog specific property: `%s` under catalog section: `%s`. This API is published under catalog: `%s`

Explanation

The API is published to a specific catalog, and other catalog-specific `x-ibm-gateway-*` properties were found under other catalogs.

Response

If you want to move this API to other catalogs, apply these properties manually to the policies in the assembly.

Severity

info

API36 `x-ibm-gateway-*` API Property: `%s` found to have invalid value: `%s`.

Explanation

See message text.

Response

Check the API to ensure that the API property has the correct value. For more information on the API property, see the appropriate section of the IBM API Connect Knowledge Center.

Severity

error

API37 JSON Schema contains an invalid reference.

Explanation

See message text.

Response

Confirm that your schema definitions are valid. If you find errors, fix them.

Severity

info

API38 XSD generation ignoring references beyond limit set by property.

Explanation

XSD generation from JSON schema uses the `x-ibm-gateway-schema-definition-reference-limit` property value to determine how many recursions to go in circular references.

Response

Severity

info

API39 An error occurred while generating the XSD for `%s` definition.

Explanation

See message text.

Response

Confirm that your JSON schema is valid before continuing.

Severity

warn

API40 Skipping JSON Schema definition: `%s` with multiple roots or not intended for XML data.

Explanation

See message text.

Severity

info

API41 Set `chunked-uploads` value to `false` to emulate v5 behavior.

Explanation

For information about the Allow chunked uploads property in the Invoke policy, see Invoke.

Severity

info

API42 Input option `chunked-uploads` set to `true`, which is the API Gateway `chunked-uploads` default. All invoke and proxy 1.5.0 and 2.0.0 policies will use this default value.

Explanation

For information about the Allow chunked uploads property in the Invoke policy, see Invoke.

Severity

info

API43 Created `compatibility:` section for API-wide toggles set by migration utility.

Explanation

The migration utility generates a compatibility section that allows DataPower to read in custom settings to for compatibility between v5 and API Gateway.

Severity

info

API44 Set compatibility toggle `%s` to value: `%s`.

Explanation

See message text.

Severity

info

API45 Compatibility toggle: `%s` set to value: `%s`, which is the same as the API Gateway default.

Explanation

The migration utility input specified to set a compatibility toggle to a value that is already the default. Therefore, no change was made in the API as the default will automatically be used.

Severity

info

API46 Updated `securityDefinition`: `%s` with new name: `%s` as specified in toggle input: `%s`.

Explanation

See message text.

Severity

info

API47 `application-authentication` was found to be set, adding `application-authentication-source` and `custom-header-name` defaults.

Explanation

In v5, **`application-authentication-source`** does not exist. In API Gateway, it is a new option that must be set if authentication is set. Therefore, the migration utility automatically sets **`application-authentication-source`** to its most-compatible default, and as a result also sets **`custom-header-name`**. If **`application-authentication`** is not set in the v5 API, the migration utility does not set **`application-authentication-source`** and **`custom-header-name`**.

Severity

info

API48 `%s` found in API definition `%s`, changing the value to a string null.

Explanation

See message text.

Severity

info

API49 Changed `$(request.body*)` to `$(request.parsed_body*)` in: `%s` to use parsed copy of data.

Explanation

In the API Gateway, the **`request.body`** context is never parsed and cannot be evaluated. The parse policy added to the beginning of the assembly automatically copies **`request.body`** into **`request.parsed_body`** and parses that copy. The reference to **`request.body`** has been changed to use this new context.

Severity

warn

API51 Added missing path parameter definition for path `%s` operation `%s` parameter `%s`.

Explanation

See message text.

Severity

info

API52 Added missing path parameter reference for path `%s` operation `%s` parameter `%s`.

Explanation

See message text.

Severity

info

API53 A path parameter reference `%s` is not a path parameter.

Explanation

See message text.

Severity

warn

API54 A parameter reference `%s` is not defined.

Explanation

See message text.

Severity

warn

API55 Definition: %s is missing property 'Body' or 'properties', this is an invalid SOAP definition.

Explanation

The structure of the SOAP definition is invalid. For example, if the definition contains a SOAP fault that is not within the SOAP body, then the definition is invalid.

Severity

error

API56 Catalog specific API Property found without a corresponding default property: %s for catalog: %s, created empty string default property at the API level.

Explanation

See message text.

Severity

info

API57 Definition reference: %s is incorrect, and should be a string of form '#/definitions/foo' where 'foo' is an existing definition

Explanation

See message text.

Response

For example, the following reference is invalid:

```
moreDetails:
          $ref: '#definitions/MoreDetails'
```

To make this a valid reference, use the following form:

```
moreDetails:
          $ref: '#/definitions/MoreDetails'
```

Severity

error

API58 `securityDefinition` property encountered without a `security` property. An empty `security` property is added.

Explanation

See message text.

Severity

info

API59 The missing referenced definition `%s` was added to the swagger.

Explanation

See message text.

Severity

info

API60 The API property name `%s` is invalid and has been removed from the swagger.

Explanation

API properties with an invalid characters such as `$` and parentheses are ignored.

Severity

info

API61 Set buffering property to true.

Explanation

APIs will always have buffering enabled, as v5 did not support streaming.

Severity

info

API62 A query based security definition `%s` was present. A new security definition `%s` was created to match implicit v5 behavior.

Explanation

The security definitions in v5 for an API key that was specified as a query parameter were configured using the key names `client_id` and `client_secret`. However, this behavior implicitly provided the ability to also use query parameters `app_id` and `app_secret`. The specification of `app_id` and `app_secret` must be done explicitly in v10.

Severity

info

API63 A security set was created with security definition references `%s` to match implicit v5 behavior.

Explanation

The security definitions in v5 for an API key that was specified as a query parameter were configured using the key names `client_id` and `client_secret`. However, this behavior implicitly provided the ability to also use query parameters `app_id` and `app_secret`. The specification of `app_id` and `app_secret` must be done explicitly in v10.

Severity

info

API64 Suffix %s appended to API `version`.

Explanation

See message text.

Severity

info

API65 The referenced definition %s was changed to %s.

Explanation

The referenced definition contained a / character in the name and was not defined in the API. The / character has been removed to allow the API to publish during `archive:push`.

Severity

info

API66 Security has been removed as there are no associated security definitions.

Explanation

The API security is extraneous without associated security definitions.

Severity

info

API67 The API property `x-ibm-gateway-framework-preserve-escaped-reverse-solidus` does not exist in the API Gateway. The property has been removed from the YAML file.

Explanation

This v5 API property is not supported by the API gateway and has been removed. If the `x-ibm-gateway-framework-preserve-escaped-reverse-solidus` API property is present with a `true` value, it will be used by the migration utility when migrating xslt, gatewayscript, and map policy source code to produce the same result as v5 would have produced.

Severity

info

API68 For path %s, the property name %s is invalid and has been removed from the swagger.

Explanation

A property of an API path that has a null value is invalid and will be removed from the path.

Severity

info

- GWS26

GWS02 This `gatewayscript` policy was added before the newly converted `switch` policy in the assembly to assist with the condition logic.

Explanation

A conditional policy from a v5 API is converted to a `switch` policy in the API Gateway. The v5 API uses GatewayScript for the `if` and `switch` policies, whereas the API Gateway condition syntax is JSONata based. These conditions have been moved into a `gatewayscript` policy that will execute immediately before the `switch` policy. The switch conditions will use results from the `gatewayscript` policy to execute the correct assembly path.

Response

Review the changes to ensure that the `switch` policy result will be consistent with the v5 API.

Severity

info

GWS04 Found `gatewayscript` policy. Porting might be required.

Explanation

Review the `gatewayscript` policy and make any necessary changes. The following list includes examples of some of the differences between `gatewayscript` code in v5-compatible APIs and API Gateway.

- Calls that reference the `request.parameters` context variable in v5-compatible APIs might not produce the same results in API Gateway. For example, consider the following call in a v5-compatible API.

  ```
  apim.getvariable('request.parameters.org_name')
  ```

  This call is not equivalent to the following call in an API Gateway API.

  ```
  context.get('request.parameters.org_name')
  ```

  The `context.get()` call in API Gateway supports multiple occurrences of the same parameter variable. Therefore, it returns structured JSON for retrieving parameters, as in the following example return.

  ```
  "{\"locations\":[\"query\"],\"values\":[\"sandbox-test-org\"]}"
  ```

  For this example, the `apim.getvariable` call should be changed to the following call in API Gateway.

  ```
  ((context.get('request.parameters.org_name)  || {}).values || []).slice(-1)[0]
  ```

- Access to `header-metadata` is not supported in API Gateway. In some cases, the call can be edited to conform to the API Gateway specification. For example, the call `hm.current.remove("Accept-Encoding");` can be replaced in API Gateway with `context.message.header.remove("message.headers.Accept-Encoding")` or `context.clear("message.headers.Accept-Encoding").`
  However, if you are using `header-metadata` to set the response message header before the `proxy` policy, you must add a `gatewayscript` policy after the `invoke` policy to set the header on the response message.
- In v5 and in v10 API Gateway, `apim.getvariable()` returns an XML node set if an XML node set was set in the variable being retrieved. In v10 API Gateway, `context.get()` always returns an XML document, even if an xml node set was set in the variable. The API may require modification to work properly.
- In both v5 and v10 API Gateway, using the `apim.getvariable()` function on XML data returns an XML NodeList object. In v10 API Gateway, using the `context.get()` function on XML data returns an XML document. Consider this change before switching to `context.get()` using the `optimize-gws` migration configuration option, as API behavior may change as a result.

Severity

warn

GWS05 Added `require(`apim`)` function to `gatewayscript` policy to conform to the API Gateway specification.

Explanation

See message text.

Response

Review the changes to ensure that the `gatewayscript` policy result will be consistent with the v5 API.

Severity

info

GWS06 Found `require('header-metadata');` in the `gatewayscript` source.

Explanation

The `header-metadata` module is not supported in the API Gateway. All API context variables in the API Gateway are in the global context module. You can access the context variables directly using `context.set()` or `context.get()`.
For more information about using context variables in `gatewayscript` policies in API Gateway, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Response

For better performance, either use the `--optimize-gws=true` toggle when running the migration utility, or use the context module for native API Gateway performance.
For more information about `header-metadata`, see Access to the headers object in the IBM DataPower Gateways documentation.

Severity

info

GWS07 Replaced `require('local:///isp/policy/apim.custom.js')` with `require('apim')` to conform to the API Gateway specification.

Explanation

The v5 `gatewayscript` compatibility module does not exist on the local file system in the API Gateway. The `require` function for this module was present in the `gatewayscript` code and has been changed for API Gateway compatibility.

Severity

info

GWS08 Empty source `gatewayscript` found.

Explanation

See message text.

Response

Consider updating the empty `gatewayscript` policy or remove it from the assembly for better performance.

Severity

warn

GWS09 Found `require('fs')` in the `gatewayscript` source.

Explanation

The `fs` module is supported in the API Gateway. Some API Gateway configuration folders have restricted access.

Severity

info

GWS10 Found `require('service-metadata')` in the `gatewayscript` source.

Explanation

See message text.

Response

The Gatewayscript examples in the following table show how the service variables map to API Gateway metric functions. To obtain the metric data, use the `getMetricData()` API of the `context.metric` object in DataPower API Gateway, as in the following example.

```
var md = context.metric.getMetricData();
```

For more information about the `context.metric` object, see context.metric object for API Gateway services in the IBM DataPower Gateways documentation.

v5 MPGW service variable	Gatewayscript example	Description
`dp:variable('var://service/time-response-complete')`	`md.filter(n => n.type === 'assembly-invoke').slice(-1).endTime`	The end time of the last assembly-invoke metric data.
`dp:variable('var://service/time-elapsed')`	`md.slice(-1).endTime`	The end time of the last element in the metric data array.
`dp:variable('var://service/time-forwarded')`	`md.filter(n => n.type === 'assembly-invoke').slice(-1).requestTime`	The request time of the last assembly-invoke metric data.
`dp:variable('var://service/URL-out')`	`md.filter(n => n.type === 'assembly-invoke').slice(-1).targetURL`	The target URL of the last assembly-invoke metric data.
`dp:variable('var://service/mpgw/request-size')`	`md.filter(n => n.type === 'assembly-invoke').slice(-1).requestSize`	The request size of the last assembly-invoke metric data.
`dp:variable('var://service/mpgw/response-size')`	`md.filter(n => n.type === 'assembly-invoke').slice(-1).responseSize`	The response size of the last assembly-invoke metric data.

Severity

info

GWS11 Found `require('mgmt')` in the `gatewayscript` source.

Explanation

The `mgmt` module is not supported in the API Gateway.

Response

Remove use of the `mgmt` module from the source code.

Severity

error

GWS12 Found `require('policy/policy-utility')` or `require('policy/policy-utility.js')` in the `gatewayscript` source.

Explanation

`policy-utility` is a DataPower module that is not supported in the API Gateway.

Response

Remove use of the `policy-utility` module from the source code.

Severity

error

GWS18 Found `gatewayscript` containing session function: `%s` and replaced with API Gateway native `%s`

Explanation

See message text.

Severity

info

GWS19 Invalid `gatewayscript` found. The gateway script could not be parsed due to `%s`

Explanation

See message text.

Severity

warn

GWS20 Found `gatewayscript` containing apim function: `%s`. No replacement was performed. The closest match is '%s', but it may not work in all situations.

Explanation

See message text.

Severity

warn

GWS21 Found `gatewayscript` containing session context function: `%s`. No replacement was performed. The closest match is '%s', but it may not work in all situations.

Explanation

See message text.

Severity

warn

GWS22 Found `gatewayscript` containing: `%s` and replaced with API Gateway equivalent context var of: `%s`

Explanation

The following context variable names differ between v5 and v10 API Gateway. The migration utility replaces the v5 variable name with the equivalent v10 API Gateway variable name. For more information, see API Connect context variables.

v5 context variable	v10 API Gateway context variable
`env.path`	`api.catalog.path`
`env.name`	`api.catalog.name`
`client.app.type`	`client.app.lifecycle-state`

Severity

info

GWS24 Found gatewayscript policy containing api.document. Adding a gatewayscript policy to populate the api.document context.

Explanation

The migration utility added a gatewayscript policy before the gatewayscript policy that contains `api.document`. The additional gatewayscript policy is required to populate the `api.document` context.

Severity

info

GWS25 Replaced TLS Profile name `webapi-sslcli-mgmt` or `api-sslcli-all` with default TLS profile name `api-ssl-client-all` to conform to the API Gateway specification.

Explanation

See message text.

Severity

info

GWS26 Removed %s `\\` characters to conform to the API Gateway specification.

Explanation

The processing of v5 API metadata would implicitly remove extraneous \\ characters. The source property of the gatewayscript policy has been changed to removed these characters as they would have been removed in v5.

- INV18
-

INV01 Moved `x-ibm-gateway-decode-request-params` from API properties to each `invoke` policy.

Explanation

This v5 API property only applies to the **invoke** and **proxy** policies. In API Gateway, the functionality of this property is implemented as an option in the **invoke** policy. This change was made for the following purposes.

- The option is now clearly visible in the **invoke** policy, making it easy to identify available options.
- Each use of the **invoke** policy can now have a different setting.

Severity

info

INV02 Moved `x-ibm-gateway-invoke-keep-payload` from API properties to the `keep-payload` `invoke` property where applicable.

Explanation

This v5 API property applies only to the **invoke** policy. In API Gateway, the functionality of this property is implemented as an option in the **invoke** policy.
This change was made for the following purposes:

- The option is now clearly visible in the **invoke** policy, making it easy to identify available options.
- Each use of the **invoke** policy can now have a different setting.

Severity

warn

INV03 Moved `x-ibm-gateway-queryparam-encode-plus-char` from API properties to each `invoke` policy.

Explanation

This API property only applies to the Invoke policy. In API gateway, this property is an option in the Invoke policy.
This change was made for the following purposes:

- The option is now clearly visible on the invoke policy, making it easy to identify available options.
- Each use of the invoke policy can now have a different setting.

Severity

info

INV04 Added `parse` policy immediately after the `invoke` policy to parse the `invoke` output.

Explanation

The **invoke** policy output context in the API Gateway is not parsed. For compatibility with the v5 API, the **invoke** policy output context will be explicitly parsed by a **parse** policy that has been added to execute immediately after the **invoke** policy.

Severity

info

INV05 Removed `x-ibm-gateway-invoke-suppress-clientid` API property from the YAML file and replaced it with allowlists and blocklists to conform to the API Gateway specification.

Explanation

This v5 API property applies only to the **invoke** policy. In API Gateway, the functionality of this property is implemented as an option in the **invoke** policy.
This change was made for the following purposes:

- The option is now clearly visible in the **invoke** policy, making it easy to identify available options.
- Each use of the **invoke** policy can now have a different setting.

Severity

warn

INV06 Found `invoke` policy. Converted to API Gateway `invoke` policy.

Explanation

See message text.

Severity

info

INV07 The API property `x-ibm-gateway-invoke-emulate-v4-soap-error` does not exist in the API Gateway.

Explanation

A **`x-ibm-gateway-invoke-emulate-v4-soap-error`** property was found. This property does not exist in the API gateway.

Response

Remove the **`x-ibm-gateway-invoke-emulate-v4-soap-error`** property from the API.

Severity

error

INV08 Incorrect timeout value of `%s` found in `%s` policy, updated to `60` seconds.

Explanation

The **`timeout`** property of the v5 **`invoke`** policy is invalid. It must be a numeric data type. It has been set to the default value of **`60`**.

Response

Correct the timeout value if the default value does not satisfy the requirements of the policy.

Severity

info

INV09 Renamed the `keepPayload` property in the `invoke` policy to `keep-payload`.

Explanation

See message text.

Severity

info

INV10 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as the `x-ibm-gateway-invoke-suppress-clientid` property is undefined or not set in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to not send the **`X-IBM-Client-Id`** HTTP header to the invoke target. The **`x-ibm-gateway-invoke-suppress-clientid`** is not provided, so the header will not be sent. The API Gateway accomplishes this behavior by adding the header to the **`invoke`** policy header-control blocklist.

Severity

info

INV11 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as the `x-ibm-gateway-invoke-suppress-clientid` property is set to `true` in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to not send the **`X-IBM-Client-Id`** HTTP header to the invoke target. The **`x-ibm-gateway-invoke-suppress-clientid`** property is provided with a value of **`true`**, so the header will not be sent. The API Gateway accomplishes this behavior by adding the header to the **`invoke`** policy header-control blocklist.

Severity

info

INV12 Removed `x-ibm-gateway-optimize-invoke` API property from the YAML file and converted the `invoke` policy to conform to the API Gateway specification.

Explanation

This v5 API property is not supported by the API Gateway.

Severity

info

INV13 Added `set-variable` policy to preserve `X-IBM-Client-Id` HTTP header before the `invoke` policy, as `x-ibm-gateway-invoke-suppress-clientid` is set to `false` in the v5c YAML input file.

Explanation

By default in the API Gateway, the **`X-IBM-Client-Id`** HTTP header is not copied from the inbound request headers to the message context headers used by the **`invoke`** policy. This request header will be copied to the message context headers so that it will be available to be sent by the **`invoke`** policy.

Severity

warn

INV14 Added `gatewayscript` policy for `x-ibm-gateway-invoke-v4-nomap-emulation` as the property is set to `true` in the v5-compatible YAML input file.

Explanation

The v5 **`invoke`** policy used this property internally, but this behavior is not supported by the API Gateway **`invoke`** policy. A **`gatewayscript`** policy that implements the behavior of this v5 API property has been added to execute after the **`invoke`** policy.

Severity

info

INV15 Invoke `keep-payload` property has been set to the value of the API property `x-ibm-gateway-invoke-keep-payload`.

Explanation

Although not supported by the v5 UI, a **`keep-payload`** property in the **`invoke`** policy is always used if present to control this behavior. If not present in the policy, the API property is used instead. The policy property is not present, but the API property is present, therefore the **`keep-payload`** property in the API Gateway will use the v5 API property.

Severity

info

INV16 Set `keep-payload` setting to `true`.

Explanation

The **`keep-payload`** setting is set based on the following conditions:

- For an **`invoke`** policy that meets all of the following criteria, the **`keep-payload`** property is always set to **`true`**.
  - The policy is at the end of the assembly.
  - The API property **`x-ibm-gateway-optimize-invoke`** is not set to **`false`**.
  - The **`invoke`** policy does not contain a **`stop-on-error`** property.
- For an **`invoke`** policy that does not meet the above criteria, the **`keep-payload property`** is set to one of the following values, in order of precedence.
  - The value of **`keepPayload`** property, if it is set.
  - The value of the API property **`x-ibm-gateway-invoke-keep-payload`**, if it is set.
- For an **`invoke`** policy that meets none of the above criteria, the **`keep-payload`** property is not set at all.
- For a **`proxy`** policy, the **`keep-payload`** property is always set to **`true`** after it is converted to an **`invoke`** policy.

Severity

info

INV17 Invoke policy set to `invoke_1.5.0`, converting invoke to `invoke_1.5.0`

Explanation

See message text.

Severity

info

INV18 Set `final-action` parameter on `invoke_1.5.0`

Explanation

If the **`invoke_1.5.0`** policy is last in the assembly, the migration utility adds the **`final-action`** parameter, which ensures that the policy sends output to the message context. If **`invoke_1.5.0`** is not last in the assembly, the policy adds a parse after the wrapper policy to parse the output.

Severity

info

JSON-to-XML policy messages

- J2X01
- J2X02

J2X01 Added a `parse` policy to execute before the `json-to-xml` policy.

Explanation

A v5 `json-to-xm` policy must have the current API Gateway context parsed explicitly prior to execution. The `parse` policy has been added to execute before the `json-to-xml` policy.

Severity

info

J2X02 Found `json-to-xml` policy and converted to API Gateway `json-to-xml`.

Explanation

See message text.

Severity

info

JWT-Generate policy messages

- JTG01
- JTG02
- JTG03

JTG01 JWE properties are missing in the `jwt-generate policy`, so encryption has been disabled.

Explanation

If `jwe-enc` or `jwe-alg` is specified, then at least one of `jwe-jwk` and `jwe-crypto` must also be specified.

Severity

warn

JTG02 JWS property is missing in the `jwt-generate policy`, so signing has been disabled.

Explanation

If `jws-alg` is specified, at least one of `jws-jwk` or `jws-crypto` must also be specified.
A private key must be specified, which can be either a JSON web key or a cypto object.

Severity

warn

JTG03 Converted the `jwt-generate` policy to the API Gateway `jwt-generate` policy .

Explanation

See message text.

Severity

info

LTPA-Generate policy messages

- LTPA01

LTPA01 Found v5-compatible `ltpa-generate` policy. Because this policy does not exist in the API Gateway, it is unchanged.

Explanation

The `ltpa-generate` policy is not available in the API Gateway.

Response

Remove the `ltpa-generate` policy from the API.

Severity

error

Map policy messages

- MAP01
- MAP02
- MAP03
- MAP04
- MAP05
- MAP06

MAP01 "Moved `%s` from API properties to each `map` policy as map option: `%s`."

Explanation

This v5 API property applies only to the `map` policy. In API Gateway, the functionality of this property is implemented as an option in the `map` policy.
This change was made for the following purposes.

- The option is now clearly visible on the `map` policy, making it easy to identify available options.
- Each use of the `map` policy can now have a different setting.

Severity

info

MAP02 Replaced %s with %s to conform to the API Gateway syntax specification.

Explanation

API Connect Version 5 treats a map value property with a string quoted with \" or \\\" as the same, specifically as a double quote. This is not supported in the API Gateway. The \\\ is converted to a single \.

Severity

info

MAP03 Converted `map` to API Gateway `map` for conformance."

Explanation

See message text.

Severity

info

MAP04 Set `map` option of `mapResolveApicVariables` to previous default of `true` for compatibility.

Explanation

If a map policy is found to not have `mapResolveApicVariables` set, the option is set to true to maintain backwards compatibility.

Severity

info

MAP05 Set `map` option of `mapParseXMLOutput` to `true` for compatibility.

Explanation

This property is always set by the migration utility to maintain compatibility with v5. If XML data is output from the `map_2.0.0` policy, then the data is parsed before it reaches `<output>.body`.

Severity

info

MAP06 Removed %s `\\` characters to conform to the API Gateway specification.

Explanation

The processing of v5 API metadata would implicitly remove extraneous \\ characters. The value properties of the map policy action have been changed to remove these characters as they would have been removed in v5.

Severity

info

Proxy policy messages

- PRX06
- PRX07
- PRX08
- PRX09
- PRX10
- PRX11
- PRX12
- PRX13
- PRX14
- PRX15

PRX01 Found `proxy` policy and converted to API Gateway `invoke` policy, as `proxy` does not exist in the API Gateway.

Explanation

A **`proxy`** policy was found. The policy was converted to an **`invoke`** policy in the API gateway.

Response

Review the changes to ensure that the **`invoke`** policy result will be consistent with the v5 API. Alternatively, you can specify that the migration utility convert **`proxy`** policies to **`proxy_1.5.0`**, which is a backward-compatible policy available in the API Gateway.

Severity

info

PRX02 Removed `x-ibm-gateway-proxy-suppress-clientid` API property from the YAML file and replaced it with allowlists and blocklists to conform to the API Gateway specification.

Explanation

This v5 API property applies only to the **`proxy`** policy. In the API Gateway, this property is represented by the header control and parameter control options in the **`invoke`** policy to either allow or restrict the **`X-IBM-Client-Id`**
`header` or **`client_id`** parameter being sent to the backend server.
This change was made for the following reasons.

- The option is now clearly visible in the **`invoke`** policy, making it easy to identify available options.
- Each use of the **`invoke`** policy can now have a different setting.

Severity

warn

PRX03 Set policy `title` to `invoke` as this is now an `invoke` policy.

Explanation

The functionality of the v5 **`invoke`** and **`proxy`** policies has been merged into the API Gateway **`invoke`** policy. The **`title`** property of the policy was changed to **`invoke`**.

Severity

info

PRX04 Proxy: Changed `No-Cache` to lowercase `no-cache`.

Explanation

See message text.

Severity

info

PRX05 Proxy: Changed `Time-to-Live` to lowercase `time-to-live`.

Explanation

See message text.

Severity

info

PRX06 Proxy: Changed `Protocol-Based` to lowercase `protocol`.

Explanation

See message text.

Severity

info

PRX07 `client_id` query parameter suppressed using parameter-control blocklist, as `x-ibm-gateway-proxy-suppress-clientid` is set to `true` in the v5-compatible YAML input file.

Explanation

The v5 default behavior is to send the **client_id** query parameter to the proxy target. The **x-ibm-gateway-proxy-suppress-clientid** property was provided with a value of **true**, indicating not to send this query parameter. The API Gateway accomplishes this behavior by adding this query parameter name to the parameter-control blocklist of the policy.

Severity

info

PRX08 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as `x-ibm-gateway-proxy-suppress-clientid` is set to `true` in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to not send the **X-IBM-Client-Id** HTTP header to the proxy target. The **x-ibm-gateway-proxy-suppress-clientid** property was provided with a value of **true**, indicating not to send this HTTP header. The API Gateway accomplishes this behavior by adding this header name to the header-control blocklist of the policy.

Severity

info

PRX09 `X-IBM-Client-Id` HTTP header suppressed using header-control blocklist, as `x-ibm-gateway-proxy-suppress-clientid` is undefined or not set in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to not send the **X-IBM-Client-Id** HTTP header to the proxy target. The **x-ibm-gateway-proxy-suppress-clientid** property was not provided, indicating not to send this HTTP header. The API Gateway accomplishes this behavior by adding this header name to the header-control blocklist of the policy.

Severity

info

PRX10 `client_id` not suppressed in query parameter, as `x-ibm-gateway-proxy-suppress-clientid` is undefined or not set in the v5-compatible YAML input file.

Explanation

The v5 default behavior was to send the **client_id** query parameter to the proxy target. The **x-ibm-gateway-proxy-suppress-clientid** property was not provided, indicating to send this query parameter. No API Gateway **invoke** policy configuration is required to emulate this behavior.

Severity

warn

PRX11 `output` deleted as this policy is the last policy in the assembly flow.

Explanation

The v5 **proxy** API can specify an output context that makes the **proxy** response available for subsequent policies, but that response was also made available as the API response, should a subsequent policy not update the message context. When the **proxy** policy is the last policy in the v5 assembly, this output is removed, which allows the API Gateway **invoke** response to be returned to the client.

Severity

info

PRX12 Added `gatewayscript` policy to copy the proxy policy headers, status, and output to `message` context.

Explanation

A v5 **proxy** policy that specifies an output response context name is not the last policy in the assembly flow. A **gatewayscript** policy has been added after the API Gateway **invoke** policy. The **gatewayscript** policy copies the contents of the response context to the message context to emulate v5 behavior.

Severity

warn

PRX13 Added `set-variable` policy to preserve `X-IBM-Client-Id` HTTP header immediately before the proxy as `x-ibm-gateway-proxy-suppress-clientid` was set to `false` in the V5-compatible YAML input file.

Explanation

By default in the API Gateway, the `X-IBM-Client-Id` HTTP header is not copied from the inbound request headers to the message context headers used by the `invoke` policy. This request header will be copied to the message context headers so that it will be available to be sent by the `invoke` policy.

Severity

info

PRX14 Proxy policy set to `proxy_1.5.0`, converting proxy to `proxy_1.5.0`

Explanation

See message text.

Severity

info

PRX15 Set `final-action` parameter on `proxy_1.5.0`

Explanation

If the `proxy_1.5.0` policy is last in the assembly, the migration utility adds the `final-action` parameter, which ensures that the policy sends output to the message context. If `proxy_1.5.0` is not last in the assembly, the policy adds a parse after the wrapper policy to parse the output.

Severity

info

Redact policy messages

- RE01
- RE02
- RE03
- RE04
- RE05
- RE06
- RE07
- RE08
- RE09
- RE10
- RE11
- RE12
- RE13
- RE14

RE01 This API Gateway `redact` policy is added to contain all v5-compatible `redact` paths targeted against the `request`.

Explanation

To redact the request body, an API Gateway `redact` policy is placed at the front of the assembly in order to redact incoming data. All redactions in v5c that are not found within a `switch`, `if`, or `operation-switch` component will be moved to this single `redact` policy.

Response

Review to confirm that this change meets the purpose of the API.

Severity

warn

RE02 API Gateway `redact` policy added to contain all v5-compatible `redact` paths targeted against `response`, `logs`, and `all`.

Explanation

In the API Gateway, `response` and `logs` data must be redacted at the end of the assembly. This API Gateway `redact` policy was added to the end of the assembly to conform to the specification. If `logs` or `all` is the v5-compatible target for the `redact` policy, then a new `log` policy will be added in `gather-only` mode to populate the `log` API context.

The API Gateway emulates the v5-compatible redact on response and logs by adding a redact action at the end of the assembly to redact the response. All redactions in v5c that are not found inside of a `switch`, `if`, or `operation-switch` component will be moved to this single `redact` policy.

Response

Review to confirm that this change meets the purpose of the API.

Severity

warn

RE03 Found v5-compatible `redact` policy. `action:path` pairs from this policy will be sorted into one or both leading and trailing API Gateway `redact` policies to conform to the API Gateway specification.

Explanation

To emulate the v5 redact on **request** and **response**, some of the **redact** policies must be moved to either the end of the assembly or beginning of the assembly. This change is necessary because the **redact** policy now works directly on the API context, so it must be placed in a specific order so that it can redact data either before it enters the assembly or after it exits the assembly.

Response

Review the changes to ensure that the **redact** policy result will be consistent with the v5 API.

Severity

warn

RE04 Found duplicate v5-compatible `redact` path of the same `redact` type. Duplicate item will not be added.

Explanation

Because multiple redactions are consolidated into the leading or trailing **redact** policy, there might be some paths that are duplicates of current paths in the consolidated **redact** policy. These paths are not added as they are redundant.

Response

Review the changes to ensure that the **redact** policy result will be consistent with the v5 API.

Severity

warn

RE05 Redaction on `request` was found in the v5-compatible YAML input file. Added first API Gateway `redact` policy to the front of the assembly after the `parse` policy to perform this redaction.

Explanation

To redact the request body, an API Gateway **redact** policy is placed at the front of the assembly in order to redact incoming data. All redactions in v5c that are not found within a **switch**, **if**, or **operation-switch** component will be moved to this single **redact** policy.

Response

Review to confirm that this change meets the purpose of the API.

Severity

info

RE06 Redact on `response`, `logs`, or `all` was found in the v5-compatible YAML input file. Added second API Gateway `redact` to the end of the assembly to perform this redaction. `log` policy also added if redact on `logs` or `all` was found.

Explanation

In the API Gateway, **response** and **logs** data must be redacted at the end of the assembly. This API Gateway **redact** policy was added to the end of the assembly to conform to the specification. If **logs** or **all** is the v5-compatible target for the **redact** policy, then a new **log** policy will be added in **gather-only** mode to populate the **log** API context.

The API Gateway emulates the v5-compatible redact on response and logs by adding a redact action at the end of the assembly to redact the response. All redactions in v5c that are not found inside of a **switch**, **if**, or **operation-switch** component will be moved to this single **redact** policy.

Response

Review to confirm that this change meets the purpose of the API.

Severity

warn

RE07 Potential JSON v5-compatible `redact` path detected.

Explanation

A v5 **redact** path has been detected that is highly likely to be targeted against JSON data. It has been converted to a JSONata path because the **redact** policy in the API Gateway uses JSONata to specify **path:**.

Response

Review to confirm that the path is meant for JSON data and it is formed properly.

Severity

warn

RE08 XML v5-compatible `redact` path detected. Converted to `redact` XPath: `%s` to JSONata: `%s`.

Explanation

A v5-compatible **redact** path has been detected that is highly likely to be targeted against XML data. It has been converted to JSONata to meet the API Gateway specification. The **redact** policy in the API Gateway uses JSONata for **path:**.

Response

Review to confirm that the path is meant for XML data and it is formed properly. Note that a malformed XPath may still publish on API Connect v10 API Gateway, but will fail subsequent API calls with a **404 API Not found** error. The API Definition DataPower object will also be in the **[down]** state because of the invalid XPath. It is also possible for an invalid XPath to work on v5 but fail on API Gateway. For example, the XPath **/test/path/** is invalid because of the trailing slash. However, this XPath will work in v5, and fail with the above scenario in v10 API Gateway.

Severity

warn

RE09 Common `redact` XPath `%s` replaced with JSONata `%s` to adhere to the API Gateway `redact` specification.

Explanation

The **redact** policy in API Gateway uses JSONata to specify the **path:**. All v5-compatible **redact** paths are converted to JSONata.

Response

Review to confirm that the changes conform to the purpose of the **redact** policy.

Severity

info

RE10 Invalid redact action: `%s` found.

Explanation

A v5-compatible **redact** policy was found to contain an invalid **action** type. Valid types include **redact** or **remove**.

Response

Review the **action** type in the **redact** policy and update to either **redact** or **remove**.

Severity

error

RE11 Added `log` policy to populate the `log` API context, because a v5-compatible `redact` policy was found targeted against `logs` or `all`. An API Gateway `redact` policy will be appended after this policy to redact the outgoing `log` data.

Explanation

The API Gateway specification requires a **log** policy in the assembly to populate the **log.request_body** and **log.response_body** context variables. After the **log** policy, the **redact** policy will then redact the contents of **log.request_body** and **log.response_body**.

Severity

warn

RE12 Added `parse` policy before `redact` policy to parse incoming data.

Explanation

The incoming data must be parsed for the **redact** policy to work properly. For example, if the incoming data contains unparsed but well-formed XML data, the **redact** policy does nothing and the data passes through. With this added **parse** policy, the XML data is parsed properly and the redaction works as expected.

Response

Review the changes to ensure that the **redact** policy result will be consistent with the v5 API.

Severity

warn

RE13 Found v5-compatible `redact` policy inside of a `switch` policy. Converted all paths to JSONata.

Explanation

If a v5-compatible **redact** policy is found within a **switch**, **if**, or **operation-switch** component, it will be left in place. If the redaction is on the response and there is an **invoke** policy at the end of the assembly, problems could arise.

Response

Review and confirm that this redaction conforms to the purpose of the API.

Severity

warn

RE14 Invalid `redact` action found: path is empty.

Explanation

The v5-compatible **redact** policy was found to have an empty path. This configuration is invalid

Response

To make the API functional, update the path in the **redact** policy.

Severity

error

Set-Variable policy messages

- SV01
- SV02
-
- SV05
- SV06
- SV07
- SV08

SV01 Found `set-variable` policy and converted to API Gateway `set-variable` policy.

Explanation

See message text.

Severity

info

SV02 Cannot recognize `set-variable` `action` `%s`. It must be `set`, `add`, or `clear` with a valid variable name.

Explanation

The v5 **set-variable** policy contains an action that is not **set**, **add**, or **clear**. The API Gateway **set-variable** policy should be modified to use the correct settings.

Severity

error

SV05 Required property `type` not found. Added `type` of `any` to conform to the API Gateway specification.

Explanation

The v5 **set-variable** policy does not have a **type** property. The type is inherent in the data type of the value. The API Gateway includes this property, which is set to the data type of the value. In conditions where the data type would be determined at runtime (for example, with a variable substitution), the value is set to **any**.

Response

Consider changing the added **type** to a more specific **type**.

Severity

warn

SV06 Required property `type` not found. Added `type` of `%s` to conform to the API Gateway specification, and it is consistent with the provided `value`.

Explanation

See message text.

Severity

info

SV07 The set-variable policy has no valid actions and has been removed from the assembly.

Explanation

See message text.

Severity

info

SV08 The set-variable action name '%s' has spaces in the name. Changing the action name to '%s'.

Explanation

See message text.

Severity

- SW04
- SW05
- SW06
- SW07
- SW08
- SW09
- SW10
- SW11
- SW12
- SW13

SW01 Found `operation-switch_1.0.0` and converted to API Gateway `operation-switch_2.0.0`.

Explanation

See message text.

Severity

info

SW03 Found `switch` policy and converted to the API Gateway `switch` policy.

Explanation

A **`switch`** policy from a v5 API is converted to an API Gateway **`switch`** policy. The v5 API uses GatewayScript syntax for conditions, whereas the API Gateway uses JSONata syntax. The conditions have been moved to a **`gatewayscript`** policy that will execute immediately before the **`switch`** policy. The **`switch`** conditions will use results from the **`gatewayscript`** policy to execute the correct assembly path.

Response

Review the changes to ensure that the **`switch`** policy result will be consistent with the v5 API.

Severity

info

SW04 Found `if` policy and converted to API Gateway `switch` policy.

Explanation

An **`if`** policy from a v5 API is converted to an API Gateway **`switch`** policy. The v5 API uses GatewayScript syntax for conditions, whereas the API Gateway uses JSONata syntax. The conditions have been moved to a **`gatewayscript`** policy that will execute immediately before the **`switch`** policy. The **`switch`** conditions will use results from the **`gatewayscript`** policy to execute the correct assembly path.

Severity

info

SW05 Found `switch` condition: `%s` and converted it to JSONata: `%s` to conform to the API Gateway specification.

Explanation

A v5 **`switch`** policy condition was converted directly into a JSONata condition. This condition does not require a **`gatewayscript`** policy that would be executed prior to the switch.

Severity

warn

SW06 `switch` condition: `%s` could not be converted to JSONata. (Error code: `%d`).

Explanation

Cannot convert an **`if/switch`** condition to JSONata. A GatewayScript policy will be added to handle the Switch logic instead. Changes are needed only if highest performance is desired. See the Response section for more details on performance. This message can appear for the following reasons.

Error code	Explanation
`1`	The auto-generated JSONata mapping file was not found.
`2`	The condition was not found in the auto-generated JSONata mapping file.
`3`	The condition resolved to empty.
`4`	An unknown error occurred

Response

To improve performance, review the condition in the v5 API and provide the JSONata for this condition.
If an **`indexOf()`** method is used to determine whether a substring is present in a value, consider using the **`$contains()`** JSONata string function . If **`indexOf()`** is used to get a substring before or after the match, consider using the **`substringBefore()`** or **`$substringAfter()`** JSONata string functions.

For more information about using JSONata to write switch conditions, see Writing switch condition scripts - DataPower® API Gateway.

Severity

warn

SW07 `switch` condition: `%s` could not be converted to JSONata or handled by `gatewayscript`.

Explanation

The **`if/switch`** condition cannot be converted to JSONata. This error can occur for the following reasons:

- A condition contains invalid Javascript.
- The condition contains multiple expressions.

Response

Review the contents of the condition and edit as necessary.

Severity

error

SW08 `switch` policy set to `switch_1.5.0`, converting `switch` to `switch_1.5.0`.

Explanation

See message text.

Severity

info

- VAL04
- VAL05
- VAL06
- VAL07
- VAL08

VAL01 Found v5-compatible `validate-usernametoken` policy. This policy does not exist in the API Gateway. No action has been taken.

Explanation

A `validate-usernametoken` policy was found. This policy does not exist in the api gateway and has been ignored.

Response

Remove the `validate-usernametoken` policy from the API.

Severity

error

VAL02 Converted `validate` policy into an API Gateway `validate` policy.

Explanation

A `validate` policy was found.

Response

Review the changes to ensure that the `validate` policy result will be consistent with the v5 API.

Severity

info

VAL03 Found `definition: request` and replaced it with `validate-against: body-param`.

Explanation

The **definition** property in the v5 **validate** policy contained a value of **request**. This value has been changed to a value of **body-param** in the **validate-against** property of the API Gateway **validate** policy.

Severity

info

VAL04 Found `definition: response` and replaced it with `validate-against: response-param`.

Explanation

The **definition** property of the v5 **validate** policy contained a value of **request**. This value has been changed to a value of **response-param** in the **validate-against**` property of the API Gateway **validate** policy.

Severity

info

VAL05 Found `soap-env` `validate` definition and converted it to the API Gateway `xml-schema` property.

Explanation

The **definition** property in the v5 **validate** policy references an OpenAPI definition. The definition referenced is for a SOAP document. This value has been changed to a value of **url** in the **validate-against**` property in the API Gateway **validate** policy. The **definition** property value has been moved to the **xml-schema** property.

Severity

info

VAL06 Set `xml-validation-mode` to `soap-body`.

Explanation

The **definition** property in the v5 **validate** policy references an OpenAPI definition. The definition referenced is for a SOAP document. This value has been changed to a value of **url** in the **validate-against** property in the API Gateway **validate** policy. The **xml-validation-mode** property value has been set to **soap-body**.

Severity

info

VAL07 Set `validate-against` to `%s`.

Explanation

The **definition** property in the v5 **validate** policy references an OpenAPI definition. This value has been changed to conform to the API Gateway **validate** policy property **validate-against** with a value of **definition** or **url**.

Severity

info

VAL08 Added `parse` policy before `validate` policy.

Explanation

A v5 **validate** policy that is configured to validate the current context payload against a schema definition must have the input of the current API Gateway context parsed explicitly prior to execution. The **parse** policy has been added to execute before the **validate** policy.

XML-to-JSON policy messages

- X2J01
- X2J02

X2J01 Added a `parse` policy to execute before the `xml-to-json` policy.

Explanation

A v5 **`xml-to-json`** policy must have the current API Gateway context parsed explicitly prior to execution. The **`parse`** policy has been added to execute before the **`xml-to-json`** policy.

Severity

info

X2J02 Found `xml-to-json` policy and converted to API Gateway `xml-to-json` policy.

Explanation

v5 **`xml-to-json`** policies are converted to API Gateway **`xml-to-json`** policies.
Note: When a v5 **`xml-to-json`** policy that contains the **`xml:space="preserve"`** attribute is migrated to API Gateway, spaces are not retained after curly braces, commas, and quotes in the JSON.

Response

Review the JSON and edit as necessary.

Severity

info

XSLT policy messages

- XSLT01
- XSLT02
- XSLT03
- XSLT04
- XSLT05
- XSLT06

XSLT01 Replaced `apim.custom`, `apim.setvariable`, and `webapi-util` with `apim.custom.xsl within xsl import and xsl include statements.

Explanation

The v5 **`xslt`** policy code that contains an xsl import or xsl include of v5 framework stylesheets that were found in the local directory of the file system have been changed to use the v5-compatible stylesheet in the store directory of the file system.

Severity

info

XSLT02 Added `parse` policy to execute before the `xslt` policy.

Explanation

A v5 **`xslt`** policy that is configured to use the current context payload as input to the stylesheet must have the current API Gateway context parsed explicitly prior to execution. The **`parse`** policy has been added to execute before the **`xslt`** policy.

Severity

info

XSLT03 Found `xslt` policy. Porting might be required.

Explanation

Review the **`xslt`** policy and make any changes required for use in API Gateway.

Response

If you want to use v5-compatible XSLT code in API Gateway, use the API Gateway extension elements and functions to ensure compatibility with API Gateway. Depending on the content of your code, you may need to make the following changes.

- Remove the `apim.setvariable-impl.xsl` stylesheet from the XSLT code. This stylesheet is not used in API Gateway. Instead, use the API Gateway extension functions to manipulate the assembly context.
- Use API Gateway extension elements to manipulate values in the assembly context. The following example uses the `apigw:set-header` extension element to set the value of the request header.

  ```
  <apigw:set-header name="'request'" value="$request" />
  ```

- Use of `dp:variable` and `dp:set-variable` functions is not supported in API Gateway. These functions should be changed to `apim:getVariable` and `apim:setVariable`. Access to session, service, and system metadata is restricted.

For more information about the API Gateway extension elements and functions, see the IBM DataPower Gateway documentation.

Severity

warn

XSLT04 `xslt` policy set to `xslt_1.0.0`, converting xslt to `xslt_1.0.0`.

Explanation

See message text.

Severity

info

XSLT05 Replaced TLS Profile name `webapi-sslcli-mgmt` or `api-sslcli-all` with default TLS profile name `api-ssl-client-all` to conform to the API Gateway specification.

Explanation

See message text.

Severity

info

XSLT06 Removed %s `\\` characters to conform to the API Gateway specification.

Explanation

The processing of v5 API metadata would implicitly remove extraneous \\ characters. The source property of the xslt policy has been changed to remove these characters as they would have been removed in v5.

Severity

info

Migration utility messages

- Catalog property updated with catalog name

Catalog property updated with catalog name Message API: {{.APIFile}}, pOrg: {{.ProviderOrg}}: Updated catalogs: property: {{.OldCatalogName}} with catalog name: {{.NewCatalogName}} based on matching catalog title: {{.FoundCatalogTitle}} since API Gateway requires catalog name instead of catalog title in `catalogs:`

Explanation

In v5, the `catalogs:` property uses names based on the Catalog Title. In API Gateway, the Catalog Name must be used. The Migration Utility attempted to find a matching Catalog Title in the same provider-org as the API, and succeeded. The `catalogs:` property that formerly used the Catalog Title has been automatically updated by the Migration Utility to use the Catalog Name of the Catalog instead.

Response

Review your API to confirm that the Catalog Name used in the `catalogs:` property is correct.

Parse actions added to the API assembly after migration

The migration utility **`apicm archive:port-to-apigw`** and **`apicm archive:port-to-apigw-v10`** commands add parse actions to the API assembly depending on the policies specified in your migration configuration.

Review the API assembly to determine if any of the parse actions or other actions added by the migration utility can be removed. For more information, see Fine-tuning APIs after migration.

Parse actions are added to the assembly according to the rules in the following tables.

Table 1. Parse actions added to the API assembly after conversion of policies to 1.0.0 or 2.0.0

Policy	Where the parse action is added
If a **POST**, **PUT**, **DELETE**, **OPTIONS**, or **PATCH** method is found	As the first action in the assembly
invoke 2.0.0	After the invoke action, except when invoke is the last action in the assembly.
json-to-xml 2.0.0	Before the json-to-xml action
proxy 2.0.0	After the proxy action
validate 2.0.0	Before the validate action
xml-to-json 2.0.0	Before the xml-to-json action
xslt 1.0.0 or 2.0.0	Before the xslt action

Table 2. Parse actions added to the API assembly after conversion of invoke and proxy policies to 1.5.0

Policy	Where the parse action is added
invoke 1.5.0	A parse action is added after the invoke if any of the following are true: • **stop-on-error** is specified • **final-action** is set to **false**. This is the default setting. • **x-ibm-gateway-optimize-invoke** is explicitly set to **false** The parse action is added because there can be a subsequent use of the output.
proxy 1.5.0	A parse action is added after the proxy if **final-action** is set to **false**.

Fine-tuning APIs after migration

After running the migration utility **apicm archive:port-to-apigw** or **apicm archive:port-to-apigw-v10** command, review the converted APIs to determine if any of the changes made by the migration utility can be modified to enhance performance and usability.

If the migration utility makes any of the following changes to your APIs, consider making the suggested changes.

- If the last policy in the assembly has output that is set to a variable that is not used afterward, remove the output set or the entire policy.
- Remove any unnecessary parse actions that the migration utility adds to the assembly. For information about the parse actions added by the migration utility, see Parse actions added to the API assembly after migration.
- If the assembly contains redact policies, verify that these policies are necessary. Delete any unnecessary redact policies.

Frequently asked questions about migrating APIs to API Gateway

Answers to some of the most frequently asked questions about migrating APIs to API Gateway.

- What is port-to-apigw?
- When is it necessary to run the port-to-apigw command, and how do I use it?
- Why is the port-to-apigw command needed for migrating to v10 API Gateway?
- What is the difference between these terms: "porting to API Gateway", port-to-apigw, and "migration"?
- What is v5 policy emulation and how does it work?
- What is the purpose of the policy parameter options in port-to-apigw?
- How do the v5 emulated policies invoke_1.5.0, proxy_1.5.0, xslt_1.0.0, and gatewayscript_1.0.0 work?
- What is the difference between the 1.5.0 and 2.0.0 versions of the invoke and proxy policies, and the 1.0.0 and 2.0.0 versions of the gatewayscript policy? Why isn't the 2.0.0 version the default version?
- Should I rewrite my GatewayScript policies?
- What is the optimize-gws option?
- What is the gateway-extension.zip file and how does it work?
- How does the migration utility migrate custom policies?
- Should I set the custom-policies-scope option to global or catalog?
- Why are my custom policies not showing up in the Assembly Editor policy palette?

What is **port-to-apigw**?

port-to-apigw is a command in the API Connect migration utility that converts all APIs, products, subscriptions, OAuth providers, and custom policies into v10 native API Gateway artifacts. These newly created artifacts live side-by-side with the original v5-compatible artifacts, and have **-apigw** appended to the end of the filename.

For more information, see Converting APIs to DataPower API Gateway.

When is it necessary to run the **port-to-apigw** command, and how do I use it?

Run this command if you are migrating to a v10 native API Gateway. Follow the migration steps that are appropriate for your v5 environment. For instructions on running the **port-to-apigw** command, see Migration steps. For information on configuring migration options, see Configuring migration options for DataPower API Gateway. For other information to help you optimize migration, see Migration considerations.

Why is the **port-to-apigw** command needed for migrating to v10 API Gateway?

The required fields, properties, settings, and configuration in v10 native API Gateway differs from v5-compatible mode. The **port-to-apigw** step in the migration process is needed to convert the artifacts to conform to the changes.

What is the difference between these terms: "porting to API Gateway", **port-to-apigw**, and "migration"?

"Porting to API Gateway" describes what the **port-to-apigw** command does in the migration utility. "Migration" is the overall purpose of the migration utility. The **port-to-apigw** step is necessary for migrating to a v10 native API Gateway. Migration can be completed without the **port-to-apigw** step if you are migrating to a v10 deployment that uses only the v5-compatible DataPower Gateway.

What is v5 policy emulation and how does it work?

The v5 policy emulation layer allows both custom policies and the 1.0.x policies to run on the native v10 API Gateway. It is deployed automatically by the API Connect migration utility to the **local:///isp** folder of the DataPower appliance when a custom policy is found in the v5 backup, or if you specify a 1.0.x policy in

the policy option for the **port-to-apigw** command. The deployment is first staged by the **port-to-apigw** command, and pushed by the **archive:push** command. Follow the steps as outlined in Migration steps.
Note that 1.5.x policies do not use v5 policy emulation, and exist only as native wrappers to the 2.0.0 implementation.

What is the purpose of the policy parameter options in **port-to-apigw**?
Input options allow you to customize your migration. If you want to use the native policies, such as invoke_2.0.0 instead of the default invoke_1.5.0-compatible option, you can select the appropriate option. However, using these options can result in migration errors that require manual changes to get your APIs up and running. If you want to be up and running quickly, it is best to use the default options for the input. The default options convert APIs in a way that is most backwards compatible with v5.
For more information about the migration configuration options, see Configuring migration options for DataPower API GatewayConfiguration parameters for migrating v5 APIs. For explanations of errors and other messages generated during migration and suggestions for manual changes to APIs, see Messages generated during conversion of APIs to DataPower API Gateway.

How do the v5 emulated policies **invoke_1.5.0**, **proxy_1.5.0**, **xslt_1.0.0**, and **gatewayscript_1.0.0** work?
When the push step of the migration utility is completed, these policies will exist on the DataPower Gateway as assembly function objects. The 1.0.x policies call the v5 policy emulation layer in order to function as if they were v5 policies. The 1.5.x policies are wrapper policies to the 2.0.0 implementation. They call the 2.0.0 policies and exist only as a compatibility layer between the original v5 policy and the new 2.0.0 policy.
What is the difference between the 1.5.0 and 2.0.0 versions of the **invoke** and **proxy** policies, and the 1.0.0 and 2.0.0 versions of the **gatewayscript** policy? Why isn't the 2.0.0 version the default version?
The 1.5.x policy implementations are native wrappers to the underlying 2.0.0 implementation. They exist only to create a compatibility layer between the v5 policy and the APIGW native policy. The **gatewayscript_1.0.0** policy uses v5 policy emulation to run as if it were on a v5 environment. The performance of the 1.0.x v5 emulation layer policies in API Gateway is the same or slightly better than the v5 and v5-compatible versions. The performance of 1.5.x policies is slightly slower than their corresponding 2.0.0 policies. You can inspect the 1.5.x wrapper implementation in Assembly Functions in DataPower Gateway.
Should I rewrite my GatewayScript policies?
Most GatewayScript policies do not require rewriting, as the native v10 API Gateway contains an enhanced compatibility layer that accepts most of the **apim** functions without modification. In most cases, GatewayScript policies require rewriting when they contain any of the following:

- inline parameters
- **require('service-metadata')** and service variables associated with it
- **require('mgmt')**
- **require('fs')**
- OAuth context variables

What is the **optimize-gws** option?
The **optimize-gws** migration option converts certain v5 gatewayscript functions to the native API Gateway implementation. This setting is optional because the compatibility layer already handles processing of original v5 gatewayscript functions. If set to true, the migration utility makes the following conversions:

- **apim.getvariable()** is converted to **context.get()**
- **apim.setvariable()** is converted to **context.set()**
- **hm.current.remove()** is converted to **context.clear()**

What is the **gateway-extension.zip** file and how does it work?
After running the **port-to-apigw** command, a **gateway-extension.zip** file is located in the **cloud/admin-org/availability-zones/default-availability-zone/gateway-services/<gateway-service>** folder. This file is automatically generated by the migration utility during the processing of the **port-to-apigw** command. It contains a **manifest.json** file, and every custom policy under the gateway service that came from the v5 backup. The **manifest.json** file contains a list of custom policies to push, and backwards-compatible policies to advertise and make available for use by APIs. These backwards-compatible policies include **invoke_1.5.0**, **proxy_1.5.0**, **xslt_1.0.0**, and **gatewayscript_1.0.0**. During the **archive:push** steps of the migration process, this zip file is pushed to the API Manager as a gateway extension.
For more information, see Gateway extensions manifest.

How does the migration utility migrate custom policies?
Custom policies are migrated in multiple steps, depending on whether the **custom-policies-scope** option is set to **global** or **catalog**. Once custom policies are pushed to the DataPower Gateway, they use the **v5 policy emulation** layer that was unpacked into the **local:///isp** folder in order to run on the native v10 API Gateway.

When **port-to-apigw** is run, the following steps are performed depending on the **custom-policies-scope** setting.

- If **custom-policies-scope** is set to **global**, and there are no duplicate custom policies with differing implementations, the custom policies under each gateway service are bundled in a **gateway-extension.zip** file. This zip file contains a **manifest.json** file that describes the contents. The **gateway-extension.zip** file is copied to the **admin-org**
gateway-service folder. These steps are performed automatically when **port-to-apigw** is run. Next, you must push the **admin-org** during the **archive:push** step, which pushes the **gateway-extension.zip** bundles (one per gateway) to the API Manager using an internal **APIC Toolkit gateway-extensions:create** call. The custom policies within the bundle are advertised on the API Manager. The custom policies and compatible legacy policies are shown in the policy pallet in the API Manager Assemble UI. These custom policies are also in the DataPower filesystem in the **local:///** folder. Note that if duplicate custom policies with the same name, version, and differing underlying implementation are found, the migration utility logs a message and automatically falls back to **catalog** scope to prevent the migration from failing.

- If **custom-policies-scope** is set to **catalog**, the custom policies under each gateway service are bundled in a **gateway-extension.zip** zip file. This zip file contains a **manifest.json** file that describes the contents. The **gateway-extension.zip** file is then copied to the **admin-org gateway-service**
folder. The custom policy definition files under each catalog are copied into the **catalog-scoped-staging** folder, where their gateway type is set to **datapower-api-gateway**. Next, you must push the **admin-org** during the **archive:push** step, which pushes the **gateway-extension.zip** bundles (one per gateway) to the API Manager using an internal **APIC Toolkit**
gateway-extensions:create call. Note that the custom policies and compatible legacy policies are not visible in the policy pallet in the UI. You can see the custom policies in the DataPower filesystem in the **local:///** folder. Before you can publish APIs that use these policies, you must push your **provider-orgs** during the **archive:push** step. The custom policy definitions as described earlier from the **catalog-scoped-staging** folder are then pushed to the API Manager automatically using an internal **APIC Toolkit policies:create** call. The APIs containing the newly migrated catalog-scoped custom policies are then published.

Note: The folders and zip files are created automatically, and you should not need to modify them. For instructions on the tasks you must perform, see Migration steps.
Should I set the **custom-policies-scope** option to **global** or **catalog**?

Global scope custom policies are visible to every catalog and org on the gateway. Catalog scope custom policies are visible only to the catalog that they were migrated from. If you plan to migrate to v10 with the intention of custom policy availability the same as it is on v5, then use the default **catalog** setting.

Why are my custom policies not showing up in the Assembly Editor policy palette?

See the following troubleshooting information: Custom policies not appearing in the policy palette after migration

Configuring migration options for DataPower API Gateway

If you are converting APIs to DataPower API Gateway, you can accept the default migration configuration or specify configuration parameters.

You can specify migration configuration parameters using either a YAML configuration file or from the command line, but not both. The **config.yml** file must be located in the same directory as the migration utility. You can specify to use this file when the migration utility is invoked using the **apicm** command with the **port-to-apigw** option, as in the following example.

```
./apicm archive:port-to-apigw <path> --use-config-file=true
```

If use of the configuration file is not specified, the migration utility uses parameters specified on the command line. If no parameters are specified, then the default parameters are used.

Some of these **port-to-apigw** configuration parameters depend upon a specific DataPower implementation to function. See the information in the following table to ensure that you have the correct version of DataPower for the parameters you want to use.

Table 1. Migration configuration options

Parameter	Valid values	DataPower version required	Description
activity-log-policy	**activity-log_1.5.0, set-variable_2.0.0**	DP 10.0.4.0+	Defines how to process the v5 activity-log policy when the migration utility rewrites the API assembly. The default value is **activity-log_1.5.0**, which changes the activity-log version to 1.5.0. When set to **set-variable_2.0.0**, the migration utility sets context variables based upon the value of the activity-log content and error-content configuration values.
chunked-uploads	**true / false** The default value is **false**.	For **invoke_1.5.0**: 10.0.1.1+, 10.0.2.0+ For **invoke_2.0.0**: 10.0.0.0+	If an **invoke_1.5.0** or **proxy_1.5.0** policy exists in an assembly in the API, then set **chunked-uploads** to **true** to enable chunked encoding for HTTP 1.1 requests to the target server. If an **invoke_2.0.0** policy exists in an assembly after the migration, then set **chunked-uploads** to **false** explicitly for the policy, as the default value for **chunked-uploads** in API Gateway is **true**.
client-id-header-override	String. The string cannot contain spaces. Follow the guidelines for **apiKey name:**. No default value.	10.0.0.0+	Override the existing **X-IBM-Client_Id** name value with the new value. In API Gateway, **x-key-type** makes it possible to define custom naming for **client_id** and **client_secret**. Example: **--client-id-header-override="acme-foo"** In this example, the **securityDefinitions** property is changed from: **foo:** **type: apiKey** **name: X-IBM-Client-Id** **in: header** to the following: **foo:** **type: apiKey** **name: acme-foo** **in: header** **x-key-type: client_id** Calls to this API must supply **acme-foo: <client-id>** in the request header instead of the original **X-IBM-Client-Id: <client-id>**.
client-id-query-override	String. The string cannot contain spaces. Follow the guidelines for **apiKey name:**. No default value.	10.0.0.0+	Override the existing **client_id** name value with the new value. In API Gateway, **x-key-type** makes it possible to define custom naming for **client_id** and **client_secret**. Example: **--client-id-query-override="acme-foo"** In this example, the **securityDefinitions** property is changed from: **foo:** **type: apiKey** **name: client_id** **in: query** to the following: **foo:** **type: apiKey** **name: acme-foo** **in: query** **x-key-type: client_id** Calls to this API must supply **?acme-foo=<client-id>** in the query parameter instead of the original **?client_id=<client-id>**.

Parameter	Valid values	DataPower version required	Description
client-secret-header-override	String. The string cannot contain spaces. Follow the guidelines for **apiKey name:**. No default value.	10.0.0.0+	Override the existing **X-IBM-Client-Secret** name value with the new value. In API Gateway, **x-key-type** makes it possible to define custom naming for **client_id** and **client_secret**. Example: **--client-secret-header-override="acme-foo"** In this example, the **securityDefinitions** property is changed from: **foo:** **type: apiKey** **name: X-IBM-Client-Secret** **in: header** to the following: **foo:** **type: apiKey** **name: acme-foo** **in: header** **x-key-type: client_secret** Calls to this API must supply **acme-foo: <client-secret>** in the request header instead of the original **X-IBM-Client-Secret: <client-secret>**.
client-secret-query-override	String. The string cannot contain spaces. Follow the guidelines for **apiKey name:**. No default value.	10.0.0.0+	Override the existing **client_secret** name value with the new value. In API Gateway, **x-key-type** makes it possible to define custom naming for **client_id** and **client_secret**. Example: **--client-secret-query-override="acme-foo"** In this example, the **securityDefinitions** property is changed from: **foo:** **type: apiKey** **name: client_secret** **in: query** to the following: **foo:** **type: apiKey** **name: acme-foo** **in: query** **x-key-type: client_secret** Calls to this API must supply **?acme-foo=<client-secret>** in the query parameter instead of the original **?client_secret=<client-secret>**.
copy-id-headers-to-message	**true / false** The default value is **false**.	10.0.1.1+, 10.0.2.0+	When set to **true**, the **client-id** header is copied from **request.headers** to **message.headers** to be passed to the backend server. Set this parameter to **true** if your invoke backend services expect the **client-id** to be passed through.
custom-policies-scope	**catalog / global** The default value is **catalog**.	10.0.0.0+	When set to **catalog**, the original v5 or v5-compatible catalog that contains the custom policy is staged for pushing to the target catalog and organization in API Gateway. When set to **global**, the custom policy is staged for pushing to API Gateway and is visible to all organizations and catalogs within that gateway. **archive:port-to-apigw** sets up the custom policies for pushing to API Gateway, but does not do the pushing. If **global** scope is used, **archive:push** of the admin organization will push all custom policies associated with the configured gateways. If **catalog** scope is used, then the **archive:push** of the admin organization will initialize the custom policies on the gateway. A subsequent **archive:push** of the provider organization is needed to advertise the custom policies in the catalogs contained within the provider organization. Note: Potential conflicts between custom policies of the same name and version are resolved according to the following rules: • When set to **global** and two policies under the same gateway service have the same name, version, and md5 hash value, then the duplicates are discarded and a message is generated. • When set to **global** and two policies under the same gateway service have the same name, version, and a differing md5 hash value, then global scope cannot be applied. Catalog scope is used and a warning is generated. • When set to **catalog**, **<orgname>_<catname>_** is appended to the zip filename to maintain uniqueness.

Parameter	Valid values	DataPower version required	Description
deploy-policies	Any combination of the following values: **gatewayscript_1.0.0**,**if_1.5.0**, **invoke_1.5.0**, **proxy_1.5.0**,**redact_1.5.0**, **switch_1.5.0**, **validate-usernametoken_1.0.0**, **xslt_1.0.0** The default values are: **if_1.5.0**, **invoke_1.5.0**, **proxy_1.5.0**, **redact_1.5.0**, **switch_1.5.0**, **validate-usernametoken_1.0.0**, **xslt_1.0.0**	For **invoke_1.5.0**, **proxy_1.5.0**, **gatewayscript_1.0.0**, and **xslt_1.0.0**: 10.0.0.0+ For **if_1.5.0** and **switch_1.5.0**: 10.0.1.1+, 10.0.2.0+ For **redact_1.5.0**: 10.0.3.0+ For **validate-usernametoken_1.0.0**: 10.0.1.3+, 10.0.2.0+	Defines which backwards-compatible policies should be advertised by DataPower to API Manager. Note: Any legacy policies that are specified in the **config.yml** file or by using the **apicm** command must also be specified by using **deploy-policies**. If these policies are not specified by using **deploy-policies**, an error is returned.
emulate-v4-plan-rate-limit	**true / false** The default value is **false**.	10.0.1.2+, 10.0.2.0+	Determines whether all APIs emulate the v4 plan rate limit. If set to **true**, then API operations do not share the rate limit. This setting matches the behavior of the **x-ibm-gateway-emulate-v4-plan-rate-limit** v5 option.
enable-api-logging	**true / false** The default value is **true**.	10.0.0.0+	Log all changes that the migration utility makes when rewriting APIs. These changes are logged as comments in the API YAML file.
enforce-required-params	**true / false** The default value is **false**.	10.0.1.1+, 10.0.2.0+	When set to **true**, required parameters are enforced, which is the default behavior in API Gateway. When set to **false**, required parameters are not enforced, even if the required parameter checkbox selected.
gatewayscript-policy	One of the following values: **gatewayscript_1.0.0**, **gatewayscript_2.0.0** The default value is **gatewayscript_2.0.0**.	10.0.0.0+	Defines which gatewayscript policy the migration utility uses when rewriting the API assembly. **gatewayscript_1.0.0**: A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use **gatewayscript_1.0.0** if the gatewayscript policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings. **gatewayscript_2.0.0**: The migration utility rewrites the existing API to gatewayscript 2.0.0. This policy supports the **header-metadata** module for compatibility with the DataPower® Gateway (v5 compatible). Specifying **gatewayscript_2.0.0** can cause migration errors or run-time errors. Use **gatewayscript_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
if-policy	One of the following values: **if_1.5.0**, **switch_2.0.0** The default value is **if_1.5.0**.	For **if_1.5.0**: 10.0.1.1+, 10.0.2.0+ For **switch_2.0.0**: 10.0.0.0+	Defines which **if** policy the migration utility uses when rewriting the API assembly. **if_1.5.0**: The migration utility rewrites the existing API to if 1.5.0. **switch_2.0.0**: The migration utility rewrites the existing API to switch 2.0.0. Specifying **switch_2.0.0** can cause migration errors or run-time errors. Use **switch_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
invoke-policy	One of the following values: **invoke_1.5.0**, **invoke_2.0.0** The default value is **invoke_1.5.0**.	10.0.0.0+	Defines which invoke policy the migration utility uses when rewriting the API assembly. **invoke_1.5.0**: The migration utility rewrites the existing API to invoke 1.5.0. **invoke_2.0.0**: The migration utility rewrites the existing API to invoke 2.0.0. Specifying **invoke_2.0.0** can cause migration errors or run-time errors. Use **invoke_2.0.0** if you are able to review and verify all changes made by the migration utility in the API YAML file.
no-rename	**true / false** The default value is **false**.	10.0.0.0+	Defines whether to append the **-apigw** suffix to artifact file names or within artifacts. When set to **false**, the files are renamed using the **-apigw** suffix and the original unpacked v5c files are also overwritten with the ported API Gateway artifacts. A **y/n** prompt appears when using this option. To bypass this prompt, use the **--accept-no-rename-deletion** option.
no-retitle	**true / false** The default value is **false**.	10.0.0.0+	Defines whether to append the **-apigw** suffix to the **title** of the migrated API, product, or OAuth provider. Set this option to **true** if you want the **title** of the migrated API, product, or OAuth provider to match the original **title** in the v5-compatible YAML file. Note that the **x-ibm-name** of API Gateway APIs and products always includes the **-apigw** suffix. The **no-retitle** option applies only to the **title**.
optimize-gws	**true / false** The default value is **false**.	10.0.0.0+	When set to **true**, gatewayscript policies are modified to map v5 functions to API Gateway functions. Setting **optimize-gws** to **true** is valid only for the **gatewayscript_2.0.0** policy. If it is set to **true** for gatewayscript_1.0.0, an error is generated. Note: Setting **optimize-gws** to **true** can result in performance enhancements. However, the modifications to gatewayscript policies by the migration utility can cause problems. When using this setting, review all gatewayscript policy modifications after migration.

Parameter	Valid values	DataPower version required	Description
`proxy-policy`	One of the following values: `proxy_1.5.0`, `invoke_2.0.0` The default value is `proxy_1.5.0`.	10.0.0.0+	Defines which proxy policy the migration utility uses when rewriting the API assembly. `proxy_1.5.0`: The migration utility rewrites the existing API to `proxy 1.5.0`. `invoke_2.0.0`: The migration utility converts the proxy policy to invoke 2.0.0. Specifying `invoke_2.0.0` can cause migration errors or run-time errors. Use `invoke_2.0.0` if you are able to review and verify all changes made by the migration utility in the API YAML file.
`redact-policy`	One of the following values: `redact_1.5.0`, `redact_2.0.0` The default value is `redact_1.5.0`.	10.0.3.0+	Defines which redact policy the migration utility uses when rewriting the API assembly. `redact_1.5.0`: The migration utility rewrites the existing API to `redact 1.5.0`. `redact_2.0.0`: The migration utility rewrites the existing API to `redact 2.0.0`. Specifying `redact_2.0.0` can cause migration errors or run-time errors, including changes to what is redacted, particularly with redactions meant for JSON payloads. Use `redact_2.0.0` if you are able to review and verify all changes made by the migration utility in the API YAML file.
`repair-wsdl-apis`	`true / false` The default value is `true`.	10.0.1.1+, 10.0.2.0+	If an API ported from V5 is created from WSDL, the WSDL is read and checked for accuracy. If `repair-wsdl-apis` is set to `true`, then the API and WSDL are automatically repaired. For example, if the WSDL ZIP file contains unnecessary files, they are automatically removed if `repair-wsdl-apis` is `true`.
`return-v5-responses`	`true / false` The default value is `false`.	10.0.1.1+, 10.0.2.0+	When set to `true`, OAuth-related messages are printed in the v5 response format. When set to `false`, OAuth-related response messages are printed in API Gateway response format.
`switch-policy`	`switch_1.5.0`, `switch_2.0.0` The default value is `switch_1.5.0`.	For `switch_1.5.0`: 10.0.1.1+, 10.0.2.0+ For `switch_2.0.0`: 10.0.0.0+	Defines which switch policy the migration utility uses when rewriting the API assembly. `switch_1.5.0`: The migration utility rewrites the existing API to switch 1.5.0. `switch_2.0.0`: The migration utility rewrites the existing API to switch 2.0.0. Specifying `switch_2.0.0` can cause migration errors or run-time errors. Use `switch_2.0.0` if you are able to review and verify all changes made by the migration utility in the API YAML file.
`use-config-file`	`true / false` The default value is `false`.	10.0.0.0+	Use the `config.yml` file that is in the same directory as the `apicm` binary file that is being executed. If this file is used, configuration options cannot be set using the command line. The purpose of the config file is to specify the command inputs given on this page, but in an easy-to-read file format (YAML).
`v5-request-headers`	`true / false` The default value is `true`.	10.0.1.2+, 10.0.2.0+	When set to `true`, the following v5-compatible request headers are set: `Via`, `X-Global-Transaction-ID`, `X-Client-IP`. When set to `false`, these request headers are not set.
`validate-usernametoken-policy`	`validate-usernametoken_1.0.0` The default value is empty.	10.0.1.3+, 10.0.2.0+	Defines whether or not to use the `validate-usernametoken` v5 emulation policy when the migration utility rewrites the API assembly. When empty, the migration utility takes no action on the policy.
`xslt-policy`	One of the following values: `xslt_1.0.0`, `xslt_2.0.0` The default value is `xslt_1.0.0`.	10.0.0.0+	Defines which gatewayscript policy the migration utility uses when rewriting the API assembly. `xslt_1.0.0`: A user-defined policy created by the migration utility. This policy uses the v5 MPGW processing rule. Use `xslt_1.0.0` if the xslt policy is dependent on v5 MPGW capabilities, such as load balancer groups or XML Manager settings. `xslt_2.0.0`: The migration utility rewrites the existing API to xslt 2.0.0. Specifying `xslt_2.0.0` can cause migration errors or run-time errors. Use `xslt_2.0.0` if you are able to review and verify all changes made by the migration utility in the API YAML file.

Example migration configurations

The following examples show configuration options using the `config.yml` file or the `apicm` command.

- The following example uses the `config.yml` file to specify the migration configuration.

```
custom-policies-scope: global
emulate-v4-plan-rate-limit: false
deploy-policies:
  - proxy_1.5.0
  - redact_1.5.0
  - invoke_1.5.0
  - gatewayscript_1.0.0
rewrite-apis:
  enable-api-logging: false
  proxy-policy: proxy_1.5.0
  redact-policy: redact_1.5.0
  invoke-policy: invoke_1.5.0
  xslt-policy: xslt_2.0.0
  gatewayscript-policy: gatewayscript_1.0.0
  if-policy: switch_2.0.0
  switch-policy: switch_2.0.0
  optimize-gws: false
  no-retitle: true
```

Use the `use-config-file` parameter when running the `apicm` command to specify that the `config.yml` file is used for migration configuration values.

```
./apicm archive:port-to-apigw <path> --use-config-file=true
```

- The following example uses the **apicm** command to specify the same settings as in the previous example.

```
./apicm archive:port-to-apigw <path> --custom-policies-scope: global --emulate-v4-plan-rate-limit: false --deploy-policies="proxy_1.5.0,redact_1.5.0,invoke_1.5.0,xslt_2.0.0,gatewayscript_1.0.0,switch_2.0.0" --enable-api-logging=false --proxy-policy="proxy_1.5.0" --redact-policy="redact_1.5.0" --invoke-policy="invoke_1.5.0" --xslt-policy="xslt_2.0.0" --gatewayscript-policy="gatewayscript_1.0.0" --if-policy="switch_2.0.0" --switch-policy="switch_2.0.0" --optimize-gws=true --no-retitle=true
```

- The following example uses the `apicm` command to specify that the default migration configuration values are used.

```
./apicm archive:port-to-apigw <path>
```

Pushing custom policies and gateway extensions to the DataPower API Gateway

Use the AMU to push the Cloud Manager admin organization's data to the Management server, which pushes custom policies and gateway extensions to your DataPower API Gateway Services.

About this task

Custom policies and gateway extensions are stored with the Cloud Manager admin organization data. To push the converted artifacts to the DataPower API Gateway Services, you push the Cloud Manager admin organization to the Management server.

Procedure

1. Log in to the Cloud Manager on the destination v10 Management Server as an Owner of the admin organization.
   Important: You must be logged in as an Owner of the admin organization to be able to migrate Cloud Manager admin organization data.
   On Windows: open a command window with Administrator privileges, and omit the "./" from the command.

   See Table 1 for the login parameters.

   Syntax:

   ```
   ./apicm login --server <cloud_manager_endpoint> --realm admin/<identity_provider> --username admin --password admin_password
   ```

   Example for standalone deployment:

   ```
   ./apicm login --server cloud-admin-ui.mgmt.dev.apic10-stack.example.test --realm admin/default-idp-1 --username admin --password 'myadminpassword'
   ```

   Example for Cloud Pak for Integration:

   ```
   ./apicm login --server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm admin/default-idp-1 --username admin --password 'myadminpassword'
   ```

Table 1. `login` parameters for the Cloud Admin organization

Parameter	Description

Parameter	Description

`--server <cloud_manager_endpoint>`	Required. The endpoint on the Management server for communication with the Cloud Manager user interface.
	
	Standalone deployment
	Example:
	`cloud-admin-ui.mgmt.dev.apic10-stack.example.test`
	The endpoint was specified when the management subsystem was installed. View the `apiconnect_api` definition in the `apiconnect-up.yml` file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples:
	• VMware: see the `cloud-admin-ui` endpoint in Deployment overview for endpoints.
	• Kubernetes: see the `spec.cloudManagerEndpoint.hosts.name` value in your management CR.
	Cloud Pak for Integration
	Syntax:
	`cpd-<APIC_namespace>.<your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance>`
	Example:
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`
	where `e2e` is *<APIC_namespace>* and `prod` is *<APIC_instance>*.
	Note: How to obtain the server URL on Cloud Pak for Integration
	Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using `oc get routes` because Zen modifies the route internally.
	a. Locate the Platform UI panel with entries for the deployment. Identify the row that has a `Type` column entry with the description `API management administration`.
	b. To display the endpoint, hover over the corresponding **prod** entry in the `Name` column for that row. The URL displays at the bottom of the panel. .
	`Name Type`
	`prod API management administration`
	`prod API management`
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/admin`
	c. Remove the trailing `/admin` from the endpoint:
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`

`--realm admin/default-idp-1`	Required. The `apicm login` example shows the expected `--realm` parameter values for a default API Connection administration organization. The default user is `admin` and the identity provider is `default-idp-1`.
	You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):`apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm`For example:
	`apic identity-providers:list --scope admin --server myserver.com --fields title,realm`
	`total_results: 2`
	`results:`
	`- title: Cloud Manager User Registry`
	`realm: admin/default-idp-1`
	`- title: Corporate LDAP user registry`
	`realm: admin/corporate-ldap`
	The `title` value indicates which identity provider to use; copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.

`--username admin`	Required. Administrative user with permissions to modify API Connect admin-org. The default user is `admin`.
`--password myadminpassword`	Required. Administrative user's password. Cloud Pak for Integration: When you installed with the top-level CR for CP4I, the password was auto-generated. To obtain the password, see step 5 in Installing API Connect:

2. Push the ported custom policies and gateway extensions to your DataPower API Gateway services.
In the same directory where you ran the `archive:unpack-v10` command, run the following command to push the ported custom policies and gateway extensions to your DataPower API Gateway services in the Cloud Manager administrative org (admin-org).

   See the parameters in Table 2 as well as the usage notes that follow the table:

   `./apicm archive:push-v10 <cloud_manager_endpoint> <path_to_admin_org> [optional flags]`

   Example for standalone deployment (optional flags omitted):

   `./apicm archive:push-v10 cloud-admin-ui.mgmt.dev.apic10-stack.example.test cloud-v10/admin-org`

   Example for Cloud Pak for Integration (optional flags omitted):

   `./apicm archive:push-v10 cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud-v10/admin-org`

   Note: If you observe error messages in your log output, you can take troubleshooting steps, and run the migration again. See Migration troubleshooting .

Table 2. Parameters for the `archive:push-v10` command

Parameter	Description

Parameter	Description
<cloud_manager_endpoint>	Required. The endpoint on the Management server for communication with the Cloud Manager user interface. Standalone deployment Example: **`cloud-admin-ui.mgmt.dev.apic10-stack.example.test`** The endpoint was specified when the management subsystem was installed. View the **`apiconnect_api`** definition in the **`apiconnect-up.yml`** file in the API Connect v10 installation project directory that you created for initial deployment of v10. Examples: • VMware: see the **`cloud-admin-ui`** endpoint in Deployment overview for endpoints. • Kubernetes: see the **`spec.cloudManagerEndpoint.hosts.name`** value in your management CR. Cloud Pak for Integration Syntax: ***<cpd-APIC_namespace.your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance>*** Example: **`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`** where **`e2e`** is *<APIC_namespace>* and **`prod`** is *<APIC_instance>*. Note: How to obtain the server parameter on Cloud Pak for Integration Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using **`oc get routes`** because Zen modifies the route internally. a. Locate the Platform UI panel with entries for the deployment. Identify the row that has a Type column entry with the description **`API management administration`** b. To display the endpoint, hover over the entry in the Name column for that row. For example, hover over the **prod** entry, as shown in bold font, and the URL displays at the bottom of the panel. **`Name Type`** **`prod API management administration`** **`prod API management`** **`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/admin`** c. Remove the trailing **`/admin`** from the endpoint: **`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`**
<path_to_admin_org>	Required, the only supported value is cloud-v10/admin-org.
`--dry-run`	Optional. Perform a dry run to test the Admin org migration output. This option creates a project directory similar to cloud-v10, but named .workdir-*<apim_admin_server>*, where you can view how the data will be loaded into your new system. This option also displays the objects that will fail due to pre-existing or missing dependencies. For more information, see the 10.0.5.x Migration Troubleshooting section on apicm command line help.

Usage notes:

- On Windows: open a command window with Administrator privileges, and omit the "./" from the command.
- Run the **`archive:push-v10`** command in the same directory where you ran the **`archive:unpack-v10`** command, and always push the ported data back to the same v10 deployment where you extracted the data.
- The **`login`** command obtains a token that expires after eight hours.
  If the token expires while the **`archive:push-v10`** command is running, the AMU generates errors. In this case, log in again and re-run the **`push`** command. The token is refreshed every time you log in. For more information, see Token expiration .
- An alternative method of viewing endpoints is to run the **`kubectl get ingress`** and get the values from the output. For example, see the values in **bold** in the following sample output:

```
r7c221d8a33-apic-portal-director api.portal.dev.apic10-stack.example.test 80, 443 21h

```

Pushing provider organization data

Use the AMU to push the provider organization data to the Management server.

About this task

Pushing the provider organization data uploads the ported OAuth Providers, draft APIs, draft products, configured gateway services, and published products to the Management server.

Procedure

1. Log in to the API Manager user interface as an Owner or Administrator of the provider organization that you want to migrate.
   If you want to login using an OIDC user registry, see Logging in to a management server with an OIDC registry.

   Important: You cannot migrate a provider organization while you are logged in with the Cloud Manager admin organization. You must be logged in as the Owner or Administrator of the provider organization whose data you will push.
   Syntax:

   ```
   ./apicm login --server <api-manager-ui-endpoint> --realm provider/<identity_provider> --username <org_username> --password <org_password>
   ```

   Example for a standalone deployment:

   ```
   ./apicm login --server api-manager-ui.dev.apic10-stack.example.test --realm provider/default-idp-2 --username org_username@example.com --password myorgpassword
   ```

   Example for Cloud Pak for Integration:

   ```
   ./apicm login --server cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod --realm provider/default-idp-2 --username org_username@ex
   ```

   Table 1. `login` parameters for Provider organizations

Parameters	Description

<api-manager-ui-endpoint>	Required. The API Manager URL endpoint on the Management server for communication with the API Manager user interface.
	
	Standalone deployment
	Example:
	`api-manager-ui.dev.apic10-stack.example.test`
	The endpoint was specified when the Management subsystem was installed. To verify your endpoint setting, do one of the following:
	• View the `apiconnect-apim-ui` definition in the `apiconnect-up.yml` file in the API Connect installation project directory.
	• In the Cloud Manager UI, select Settings > Endpoints and view API Manager URL.
	Cloud Pak for Integration
	Syntax:
	`cpd-<APIC_namespace>.<your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance>`
	Example:
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`
	where `e2e` is *<APIC_namespace>* and `prod` is *<APIC_instance>*.
	Note: How to obtain the server URL on Cloud Pak for Integration
	Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using `oc get routes` because Zen modifies the route internally.
	a. Locate the Platform UI panel with entries for the deployment. Identify the row that has a `Type` column entry with the description `API management`
	b. To display the endpoint, hover over the corresponding **prod** entry in the `Name` column for that row. The URL displays at the bottom of the panel.
	`Name Type`
	`prod API management administration`
	`prod API management`
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/manage`
	c. Remove the trailing `/manage` from the endpoint:
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`

`--realm provider/`*`identity_provider`*	Required.
	The default *identity_provider* is `default-idp-2`.You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):
	`apic identity-providers:list --scope provider --server mgmt_endpoint_url --fields title,realm`
	For example,
	`apic identity-providers:list --scope provider --server myserver.com --fields title,realm`
	`total_results: 2`
	`results:`
	`- title: Cloud Manager User Registry`
	`realm: provider/default-idp-2`
	`- title: Corporate LDAP user registry`
	`realm: provider/corporate-ldap`
	The `title` value indicates which identity provider to use; copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`
	.

`--username` *<org_username>*	Required. A user with permissions to modify the provider organization; typically this is the owner or administrator of the organization.

Parameters	Description
`--password <org_password>`	Required. The organization owner or administrator password.

2. Push the data for the provider organization.
   In the same directory where you ran the **archive:unpack-v10** command, run the following command to push the ported data to your API Manager. See the parameters in Table 2 as well as the usage notes that follow the table.

   Syntax:

   ```
   ./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> [optional flags]
   ```

   Example for standalone deployment (optional flags are omitted):

   ```
   ./apicm archive:push-v10 api-manager-ui.mgmt.dev.apic10-stack.example.test cloud-v10/provider-orgs/production_Org
   ```

   Example for Cloud Pak for Integration (optional flags are omitted):

   ```
   ./apicm archive:push-v10 cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod cloud-v10/provider-orgs/production_Org
   ```

Table 2. `archive:push-v10` parameters for provider organizations

Parameters	Description

`<api-manager-ui-endpoint>`	Required. The API Manager URL endpoint on the Management server for communication with the API Manager user interface.
	
	Standalone deployment
	Example:
	`api-manager-ui.dev.apic10-stack.example.test`
	
	The endpoint was specified when the Management subsystem was installed. To verify your endpoint setting, do one of the following:
	• View the **apiconnect-apim-ui** definition in the **apiconnect-up.yml** file in the API Connect installation project directory.
	• In the Cloud Manager UI, select Settings > Endpoints and view API Manager URL.
	Cloud Pak for Integration
	Syntax:
	`cpd-<APIC_namespace>.<your-company.domain.com>/integration/apis/<APIC_namespace>/<APIC_instance>`
	
	Example:
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`
	
	where **e2e** is *<APIC_namespace>* and **prod** is *<APIC_instance>*.
	
	Note: How to obtain the server URL on Cloud Pak for Integration
	Use the Platform Navigator UI to determine the parameter. Note that you cannot get the endpoint by using **oc get routes** because Zen modifies the route internally.
	
	a. Locate the Platform UI panel with entries for the deployment. Identify the row that has a **Type** column entry with the description **API management**
	b. To display the endpoint, hover over the corresponding **prod** entry in the **Name** column for that row. The URL displays at the bottom of the panel.
	
	Name **Type**
	
	prod **API management administration**
	prod **API management**
	
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod/manage`
	
	c. Remove the trailing **/manage** from the endpoint:
	
	`cpd-e2e.apps.test1.cp.example.com/integration/apis/e2e/prod`

`cloud-v10/provider-orgs/<pOrg_name>`	Required. The location of your provider org within the **/cloud-v10** file hierarchy you created when you ran unpacked the data archive; for example: `cloud-v10/provider-orgs/production_Org`
`--catalogs=<list_of_names>`	Optional. Push data for only the specified catalogs if you don't want to push the entire provider organization. Use this parameter to specify the names of the catalogs you want to push (to specify multiple catalogs, use a comma-separated list): `./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --catalogs=<catalog_name1,catalog_name2,catalog_name3>`
`--spaces=<list_of_names>`	Optional. Push data for only the specified spaces if you don't want to push the entire provider organization. The **--catalogs** parameter must also be specified, and exactly one catalog must be specified. Use this parameter to specify the names of the spaces you want to push (to specify multiple spaces, use a comma-separated list). For example: `./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --catalogs=<catalog_name> --spaces=<space_name1>,<space_name2>,<space_name3>`

Parameters	Description

`--products=<list_of_name:version_pairs>`	Optional. Push data for only the specified products if you don't want to push the entire provider organization. The `--catalogs` parameter must also be specified, and exactly one catalog must be specified. If spaces are enabled on the catalog, then the `--spaces` parameter must also be specified, and exactly one space must be specified. Use this parameter to specify the names and versions of the products that you want to push (to specify multiple products, use a comma-separated list of name:version pairs as shown in the following examples.
	Example: catalog with spaces
	`./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --catalogs=<catalog_name> --spaces=<space_name> --products=<prod_name1>:<prod_version1>,<prod_name2>:<prod_version2>,<prod_name3>:<prod_version3>`
	Example: catalog without spaces:
	`./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --catalogs=<catalog_name> --products=<prod_name1>:<prod_version1>,<prod_name2>:<prod_version2>,<prod_name3>:<prod_version3>`

`--dry-run`	Optional. Perform a dry run to test the Admin org migration output. This option creates a project directory similar to `cloud-v10`, but titled `.workdir-<api-manager-ui-endpoint>` where you can view how the data will be loaded into your new system. The option also displays the objects that will fail due to existing already or missing dependencies. Use this option to view the resolved URLs for where the data will be loaded, without creating resources on the new system. See Migration troubleshooting. `./apicm archive:push-v10 <api-manager-ui-endpoint> cloud-v10/provider-orgs/<pOrg_name> --dry-run`
`--no-drafts`	Optional. Do not push any draft APIs or products (draft objects are objects that have not been published). `./apicm archive:push-v10 <api-manager-ui-endpoint> <path_to_provider_org> --no-drafts` This option can be used with or without the `--catalogs` parameter.
`--drafts-only`	Optional. Only push ported draft APIs and products, and do not push any published APIs or products (draft objects are objects that have not been published). `./apicm archive:push-v10 <api-manager-ui-endpoint> <path_to_provider_org> --drafts-only` This option cannot be used with the `--catalogs` or `--no-drafts` parameters.
`--overwrite`	Optional. Overwrite any existing draft products, draft APIs, published products and their APIs, and OAuth Providers that are already on the deployment. If you set this parameter to false, these artifacts will be left intact.
`--move-subscriptions`	Optional. When this option is used, the subscriptions associated with v5-compatible-API-based products that were ported to API DataPower Gateway-based products and successfully pushed to the API Connect deployment will have their subscriptions moved to the new products, and the original v5-compatible-API-based products will be retired. This option can also be used on subsequent `archive:push-v10` commands to move the subscriptions even after the migrated products are published. Using the `--catalogs`, `--spaces`, and `--products` parameters with the `--move-subscriptions` parameters lets you narrow the set of products to have their subscriptions moved.

Usage notes:

- On Windows: open a command window with Administrator privileges, and omit the "./" from the command.
- Run the `archive:push-v10` command in the same directory where you ran the `archive:unpack-v10` command, and always push the ported data back to the same deployment where you extracted the data.
- The `login` command obtains a token that expires after 8 hours.
  If the token expires while the `archive:push-v10` command is running, the AMU generates errors. In this case, log in again and re-run the `push` command. The token is refreshed every time you log in. For more information, see Migration troubleshooting.
- The `archive:push-v10` command only pushes only the following ported objects: OAuth Providers, draft APIs, draft products, configured gateway services, and published products.
- An alternative method of viewing endpoints is to run the `kubectl get ingress` and get the values from the output. For example, see the values in **bold** in the following sample output:

```
r7c221d8a33-apic-portal-director api.portal.dev.apic10-stack.example.test 80, 443 21h

```

3. Test your newly ported products and APIs to make sure they are working as expected.
   If necessary make changes and push the updates to your API Connect deployment.

Migrating from v10 to v10 on a different form factor

Migrate an API Connect v10 deployment from one form factor to a different form factor.

If you want to move your API Connect deployment to a different platform or network environment, use the form factor migration process.

For brevity, "form factor migration" is referred to as just "migration" in the rest of this topic.

The typical use cases for the migration process are:

- Moving your API Connect deployment from one platform to another, without changing anything else. For example, if you originally deployed on Kubernetes, but want to move to OpenShift.
- Changing the endpoints of your API Connect deployment. For example, the consumer API or portal web endpoint. It is not possible to update your API Connect endpoints after installation. Also, if you want to move your API Connect deployment to a different network, it is likely that the move requires changing the API Connect endpoints.
- Combination of moving to a different platform and changing endpoints.

You do not need to use the migration process for:

- Changing your API Connect deployment profile. See:
  - Changing deployment profiles on VMware.
  - Changing deployment profiles on Kubernetes and OpenShift.
  - Changing deployment profiles on OpenShift top-level CR.
  - Changing the deployment profile on Cloud Pak for Integration.
- Backup, restore, and disaster recovery. See:
  - Backing up, restoring, and disaster recovery.
  - Backing up and restoring on VMware.

  Note:
  You can use the migration save script **`save_v10_source_configuration.py`** as an extra backup mechanism, but do not use the migration save script as an alternative to the standard backup process.

Key points and limitations of form factor migration:

- The API Connect version on the target system must match the API Connect version on the source system.
- The migration process applies only to the management and portal subsystems. The analytics and gateway subsystems do not require migration steps. The gateway receives its data from the management subsystem, and analytics database backups can be restored directly on the new deployment.

The supported migration paths are shown in the following table:

Table 1. Supported migration paths for API Connect v10

Source deployment platform of API Connect v10	Target deployment platform
Kubernetes	Cloud Pak for Integration..
Kubernetes	OpenShift Container Platform.
Kubernetes	Kubernetes.
VMware	Cloud Pak for Integration.
VMware	OpenShift Container Platform.
VMware	VMware. From V10.0.7.0 and later.
OpenShift Container Platform	Cloud Pak for Integration, keeping the same endpoints.
OpenShift Container Platform	Cloud Pak for Integration, moving to a different cluster, resulting in endpoint changes.
OpenShift Container Platform	OpenShift Container Platform, moving to a different cluster, resulting in endpoint changes.
Cloud Pak for Integration	Cloud Pak for Integration, moving to a different cluster, resulting in endpoint changes.

  Use migration scripts to migrate API Connect to another form factor, or to a different deployment on the same form factor.
- **v10 migration requirements**
  Ensure your deployment meets the migrations prerequisites and requirements.
- **v10 migration steps**
  Complete the steps that are required for your v10 migration path.
- **Migrating from OpenShift to Cloud Pak for Integration on the same cluster**
  Migrate your API Connect v10 deployment from OpenShift to Cloud Pak for Integration, while remaining on the same cluster.
- **v10 migration troubleshooting**
  Troubleshoot problems with v10 migration.

v10 migration overview

Use migration scripts to migrate API Connect to another form factor, or to a different deployment on the same form factor.

The migration process consists of the following steps:

1. Extract the data from the management and portal subsystems databases of your source system, by using the provided Python script **`save_v10_source_configuration.py`**.
2. Install your target management and portal subsystems, setting new endpoints if required.
3. Specify the mapping of any changed endpoints in a YAML file.
4. Restore the data from your source system, by using the provided Python restore scripts.

Location of v10 migration scripts

You can obtain the scripts from Fix Central, search for **`apiconnect-operator-release-files_<version_number>`**. The scripts are located in the helper_files/formFactorMigration directory:

```
apiconnect-operator-release-files_VERSION_NUMBER/helper_files/formFactorMigration
```

On Kubernetes, OpenShift, and Cloud Pak for Integration, the migration scripts are run from a client computer that has access to the Kubernetes or OpenShift cluster. Scripts are supported on Linux and macOS.

On VMware, the migration scripts are run directly on the API Connect VMs.

v10 migration planning

Consider the following information when you plan your v10 migration:

- **Data migration**
  There are two ways to migrate data:
  - Perform complete migration of data:

    Before starting migration steps on the target system, have the target system ready with the same or larger topology than what is present in the source system. This means the number of Gateways, Portals, and Analytics subsystems must be same or more than what is present in the source system. Start the migration process, map the endpoints between source and target systems, and complete the migration process. All data is migrated. The target system must be validated and tested.

    If you do not want to migrate data for some subsystems on the source system, skip those endpoints in the mapping. Then, after migration is complete, manually delete the data from Cloud Manager and the API Manager UI on the source system.
  - Perform migration in more than one step
    In this scenario, at the time of migration the API Connect target system does not have all the subsystems ready when compared to the total number of subsystems in the source system. Migration is run only for the Gateway and Portal subsystems that are available on the target system. At this point, the target system will still have some stale data related to the subsystems that are not migrated. You can then create additional subsystems (Gateways, Portals, or Analytics) on the target system, and run the necessary migration steps to complete the remaining migration process.
    - If additional Gateways or Analytics are added to the source system after completing the initial migration, you must:
      1. Add the new Gateway and Analytics related endpoints in the mapping file.
      2. Register Gateways and Portals on the target system. Complete Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
      3. Update the gateways in the catalog to point to the new Gateway systems. Complete Step 6 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
    - If additional Portals are added to the source system after completing the initial migration, you must:
      1. Add the new Portal related endpoints in the mapping file.
      2. Register gateways and portals on the target system. Complete Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
      3. Update the portals in the catalog to point to the new portal systems. Complete Step 4 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
      4. Restore portal backups for each site on the namespace where the new portal is installed. Complete Step 5 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
    - The stale data for which migration is not complete will remain on the target system until you install the additional subsystems and complete migration, or until you use the Cloud Manager or API Manager UI to manually delete it.

- Reuse of Gateways from the source system:
  1. Export the `ingress-ca` secret from the source system using the `-export_cert` flag in Preparing the source system. The secret is saved to `data/MANAGEMENT_SUBSYSTEM_NAME/ingress-ca_secret.yaml`.
  2. Install the `ingress-ca` secret manually on the target cluster. This step must be completed before you begin Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
     - **If using top-level CR on OpenShift:** The top-level CR name you are going to use while installing API Connect must be used while creating the secret name and its contents.
     - The name of the ingress-ca secret must be `TOP_CR_NAME-ingress-ca` in case of OpenShift using top-level CR, or CP4I. For Kubernetes or OpenShift using individual subsystems, it must be `ingress-ca`.
     - An example of an `ingress-ca` secret is given in the following example. If top-level CR is used, replace `TOP_CR_NAME` with the top-level CR name you are going to use to install API Connect. For Kubernetes or OpenShift using individual subsystems, all the values will be just `ingress-ca`.
     - After modifying the contents of `ingress-ca` and saving the yaml, create the secret using `oc create -f filename.yaml -n NAMESPACE`.

     ```
     apiVersion: v1
     data:
       ca.crt: CA_CRT
       tls.crt: TLS_CRT
       tls.key: TLS_KEY
     kind: Secret
     metadata:
       annotations:
         cert-manager.io/alt-names: ''
         cert-manager.io/certificate-name: TOP_CR_NAME-ingress-ca
         cert-manager.io/common-name: ingress-ca
         cert-manager.io/ip-sans: ''
         cert-manager.io/issuer-group: ''
         cert-manager.io/issuer-kind: Issuer
         cert-manager.io/issuer-name: TOP_CR_NAME-self-signed
         cert-manager.io/uri-sans: ''
       name: <TOPCR>-ingress-ca
     type: kubernetes.io/tls
     ```

  3. Run the migration steps, starting with Step 1 in Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration. Install API Connect, using the same TOP_CR_NAME (if using top-level CR), by following the remainder of the steps in Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
  4. When you complete Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration, do not map the source system gateways that are to be reused. Just skip them.
  5. Once the migration is complete, restart the gateways pods on the source system, wait for few minutes, and run the health check script to check the status of webhooks.

6. Validate the APIs running on the source system gateways.

- Delta changes
  Once the migration procedure is started, any delta changes in the source system databases are not handled by the migration scripts. These changes must be handled manually.
  - To avoid delta changes, shut down the Postgres database in the management subsystem.
    If you shutdown Postgres, you won't be able to login to the any of the API Connect UIs, or Toolkit CLI.
  - If there are delta changes to the management database after saving the configuration for the source system, you can optionally take another backup of the Management subsystem, just prior to restoring the Management subsystem. See Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Sizing
  Before installing the API Connect target system, make sure proper capacity planning is done to handle the production workloads. Ensure you have sufficient memory, CPU, and disk size as needed, based on the deployment profile being installed.
- Expected migration time
  The time required to complete migration can depend on the following:
  - The size of the management database. Backup and restore are dependent on this size.
  - Migration of the Portal and Gateway data in all the provider orgs depends on:
    - Number of provider orgs
    - Number of catalogs in these provider orgs
    - Whether Portals are configured for these catalogs
    - Total number of APIs published
  - Creation of Portal sites and restore of Portal backup depends on:
    - Deployment profile (n1, n3 etc) being used
    - Disk performance
    - Total number of Portal sites being create or restored
    - The amount of customization in a Portal site. Customization plays a role in the time needed to restore.

v10 migration requirements

Ensure your deployment meets the migrations prerequisites and requirements.

Subsystem requirements

All subsystems must be in a healthy state.

You must manually create storage classes like block storage or file system storage. Applies to all subsystems and, when installing on CP4I, to Platform Navigator.

Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

- Management subsystem:
  - You must configure management subsystems with either S3 or SFTP backups.
  - If s3 storage is being used, Postgres in the management subsystem must be stopped on the source system.
    Note:
    Shutting down Postgres is necessary in this scenario because two APIC deployments cannot both use the same S3 backup location. The target API Connect deployment will not start if Postgres on the source deployment is up and connecting to the same S3 backup location.

    When Postgres is stopped, there is no impact on the published APIs in the gateways. However, the Cloud Manager and API Manager UI will not available because the underlying microservices are down. Users are able to browse the APIs in the portal. But new consumer orgs or applications or users cannot be created.
  - If the Postgres cluster name on the target is different than the source system, restore will fail. For more information on configuring the target system, see Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Developer Portal subsystem:
  - Developer Portal subsystems must be configured with either S3 or SFTP backups.
  - For Developer Portal subsystem, you must have all the mappings between old and new endpoints and hostnames.
- Gateway subsystem:
  - If a custom gateway image is being used on the source system, the same image must be used on the target system
  - For a gateway subsystem, you must have all the mappings between old and new endpoints and hostnames.

Scripting requirements

- Python 3 and PyYAML python module must be present on the system where the scripts are run.
  To install the PyYAML module:

  ```
  pip3 install pyyaml
  ```

- Do not have any spaces in the complete directory path where the scripts are executed.
- Ensure that the API Connect version of the `apic` toolkit is the same version as for the scripts, and that the toolkit is located in the path where the scripts are executed. Validate toolkit commands to make sure the Cloud Manager and API Manager hostnames are resolved and able to run few commands. Make sure apic toolkit commands are working before trying out the scripts.
- If you are using hostnames, you may need to update the /etc/hosts file for the apic toolkit to work.
- When the scripts are run on the target system, the configuration (data directory) saved from the source system must be available in the location where scripts are present.
- Save the output logs for every script being executed.

Credentials requirements

- In all the scripts where the credentials are passed on the command line, these credentials are the admin org (Cloud Manager) credentials.
- You must be able to use **kubectl** (for native Kubernetes) or **oc** (OpenShift) commands to access the source system cluster and the target system cluster.
- To administer the admin org, you must have credentials with administrative role to access Cloud Manager.
- For provider orgs, if you do not use the migration user, and plan to use provider org credentials, you must have the provider org credentials for the API Manager interface.
- You must manually create:
  - Secrets for entitlement keys to download images from Docker registry.
  - DataPower admin credentials and secret, if the target system is native Kubernetes.
- After migration, the users on the target system will be in the same user registry as in the source system. For example, in CP4I, users from a local user registry (LUR) are not moved to a Zen user registry.

How to obtain hostnames

The hostnames used in the scripts (**--server** or **-s** or **-api_manager_hostname**) and also in the files **gateway_portal_mapping.yaml** or **provider_org_credentials.yaml** can be obtained using the following commands.

The command must be run on the source cluster or target cluster, based on the step for which the hostname is needed.

- Kubernetes:

  ```
  kubectl get ingress -n <NAMESPACE>
  ```

- OpenShift and Cloud Pak for Integration:

  ```
  oc get routes -n <NAMESPACE>
  ```

Example output on Kubernetes:

```
kubectl get ingress -n ask1
NAME                        CLASS    HOSTS                                          ADDRESS

```

How to obtain realm values

The value of realm (**--realm** or **-r**) used while running the scripts can be obtained as shown in the following examples. The realm values are for Cloud Manager (admin org) and provider org.

- Example for Cloud Manager (admin org):
  The value is passed as a command line option while running the script.

  ```
  apic identity-providers:list --scope admin --fields title,realm --server api.test1-master.fyre.example.com
  total_results: 3
  results:
    - title: Cloud Manager User Registry
      realm: admin/default-idp-1
    - title: googleoidc
      realm: admin/googleoidc
    - title: ldap1
      realm: admin/ldap1
  ```

- Example for provider org realm values:
  The value is used in **provider_org_credentials.yaml** while updating portal and gateway information in the provider orgs, when the default migration user is not used. See Step 4 and Step 6 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

  ```
  apic identity-providers:list --scope provider --fields title,realm --server api.testuser1-master.fyre.example.com
  total_results: 3
  results:
    - title: API Manager User Registry
      realm: provider/default-idp-2
    - title: googleoidc
      realm: provider/googleoidc
  ```

```
  - title: ldap1
    realm: provider/ldap1
```

Backing up subsystems

It is necessary to backup the management and portal subsystem databases on the source system:

- Backing up and restoring on VMware
- Backing up, restoring, and disaster recovery on Kubernetes and OpenShift

Limitations

1. Analytics service and data is not migrated.
2. If migrating from v10 non-CP4I environment (source apic cluster) to v10 CP4i environment (target apic cluster), make sure the Cloud Manager password for `admin` user is not `7iron-hide` on the source cluster. If default password `7iron-hide` is used, migration will fail after step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration, as configurator job assumes that the install is a fresh installation, and changes the password automatically.

v10 migration steps

Complete the steps that are required for your v10 migration path.

Before you begin, ensure you have reviewed v10 migration overview and v10 migration requirements.
If migrating from OpenShift top-level CR to Cloud Pak for Integration on the same cluster, do not follow the steps here. Instead, refer to Migrating from OpenShift to Cloud Pak for Integration on the same cluster.

- **Preparing the source system**
  Run the `save_v10_source_configuration.py` script to gather the source system configuration.
- **Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration**
  On the target system, configure a cluster, create the necessary secrets, and install API Connect.
- **Installing the target system on VMware**
  Create the project directory, configure you target deployment, create the ISO files, and deploy your VMs.
- **Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration**
  Restore the saved configuration and backups from the source system onto the target system.
- **Restoring the target system on VMware**
  Restore the saved configuration and backups from the source system onto the target system.
- **Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration**
  Verify that the target system is in a healthy state and fully configured.
- **Verifying the target system on VMware**
  Verify that the target system is in a healthy state and fully configured.

Preparing the source system

Run the `save_v10_source_configuration.py` script to gather the source system configuration.

Before you begin

Review v10 migration requirements.

About this task

The `save_v10_source_configuration.py` script:

- Creates a data directory with all configuration saved in it.
- Generates two YAML files in the same directory as the script:
  - `gateway_portal_mapping.yaml`
  - `provider_org_credentials.yaml`

  Important: The YAML files must be filled in:
  - gateway_portal_mapping.yaml must be filled in if, when restoring onto the target system, you choose to run `register_gateway_portals_in_target.py` in silent mode. See step 3.c in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
  - provider_org_credentials.yaml must be filled in if, when restoring onto the target system, you choose not to use the migration user credentials while updating Portal and Gateway information. See step 4 and step 6 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

To view script parameters:

```
python3 save_v10_source_configuration.py --help
```

Procedure

1. Create a directory called `FFM` and copy all python scripts to this directory.
2. Kubernetes, OpenShift, or Cloud Pak for Integration: Save configuration from the source system.
   To save the source system configuration, run `save_v10_source_configuration.py` with the appropriate parameters for your deployment:
   - If all subsystems are in the same namespace, and you are using username/password authentication.

This command saves configuration of all the installed subsystems in the namespace:

```
python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE
```

- If a subsystem needs to be skipped so that its configuration is not saved:
  - Skip Portal:

    ```
    python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE -skip_ptl
    ```

  - Skip Analytics:

    ```
    python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n NAMESPACE -skip_a7s
    ```

- If all subsystems are in the same namespace, and you are using SSO authentication:

  ```
  python3 save_v10_source_configuration.py --sso -s PLATFORM_API_HOSTNAME -n NAMESPACE
  ```

- If all subsystems are in different namespace, and you are using username/password authentication:

  ```
  python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns <mgmt_namespace>  -ptl_ns <ptl_namespace> -gw_ns <gw_namespace> -a7s_ns  <a7s_namespace>
  ```

- If the cluster has multiple Gateways, Portals, or Analytics subsystems distributed across namespaces in the cluster, you can save the configuration of the source system using one of the ways shown below. Multiple namespaces need to be separated by "`|`" symbol. The namespaces used in below example command are `ns1`, `ns2`, `ns3`. Both commands work the same way.

  - ```
    python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -n "ns1|ns2|ns3"
    ```

  - ```
    python3 save_v10_source_configuration.py -u USERNAME -p  PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns "ns1" -ptl_ns  "ns1|ns2" -gw_ns "ns1|ns2|ns3" -a7s_ns "ns1|ns2"
    ```

- If ingress-ca certificates must be saved or exported in the configuration, run the previous commands with `-export_cert` flag. Applicable only when you are saving management subsystem configuration.

3. VMware: Save configuration from the source system.
   On VMware appliance, save the source configuration by running the `save_v10_source_configuration.py` script on the Management and Portal nodes.

   If you have a three replica deployment, run the `save_v10_source_configuration.py` script on just one of the VMs in the cluster.

   a. Copy the `apic` toolkit and `apicup` installer to the management node.
   b. Copy the script `save_v10_source_configuration.py` to the management node:
      - If `ingress-ca` and `root-ca` certificates must be saved in the configuration, copy this script to the project directory for this appliance and upload the project directory to the appliance. The script must be run from inside the project directory.
      - If `ingress-ca` and `root-ca` certificates are not needed, just copy this script to the appliance.
   c. Change to root user (`sudo -i`) and set PATH variable to the directory where the **apic** toolkit is present. This directory must be at the beginning of the path.
   d. Change to the directory where script is located. Check the PATH to verify that the **apic** toolkit is present. To validate, use `apic login` and `apicup version`.
   e. Collect source system configuration. If certificates needed, add the flag `-export_cert` to the command.

      ```
      python3 save_v10_source_configuration.py -u USERNAME -p PASSWORD -s PLATFORM_API_HOSTNAME -r REALM_NAME -mgmt_ns default
      ```

   f. On the Management node, from the location where the script is run, download the data directory, gateway_portal_mapping.yaml, and provider_org_credentials.yaml files. Copy them to the location where the form factor migration scripts are present.
   g. Copy the `save_v10_source_configuration.py` script to the Portal node and run the script as root user, using the following command:

      ```
      python3 save_v10_source_configuration.py -ptl_ns default -skip_mgmt
      ```

      On the Portal node, from the location where the script is run, download the `data` directory and merge it with the `data` directory downloaded from the Management node.
      If multiple Portal services are configured with the Management subsystem, repeat the same operation for each Portal.

What to do next

Configure your target deployment:

- Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration
- Installing the target system on VMware

Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

On the target system, configure a cluster, create the necessary secrets, and install API Connect.

Before you begin

- Complete Preparing the source system.
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

About this task

Run the **create_secrets_in_target.py** script to create the necessary secrets. If necessary, shutdown the Postgres database, and then install API Connect, either manually or by running the **install_apic_on_ocp.py** script.

Note: For data migration, you have the option of performing a complete migration at once, or performing migration in more than one step. To review these options, see v10 migration planning.

Procedure

1. Configure a target cluster either Kubernetes or OpenShift or Cloud Pak for Integration, where you intend to migrate the source system data.
   - Note that this configuration is for the cluster only. No API Connect software is installed yet.
   - Make sure **KUBECONFIG** is set to this target cluster, so you can access the cluster using **oc** or **kubectl**.
2. Create the namespaces in the target cluster where you want the API Connect subsystems to run.
   - The namespaces can be different than the source system values.
   - If you have additional subsystems to be installed in different namespaces, create these namespaces also.
3. Run **create_secrets_in_target.py** to create the following secrets:
   - Database backup secrets for Management and Portal subsystems
   - Application credentials
   - Encryption secrets from the source system

   Usage examples:
   - If both Management and Portal are in the same namespace, or if Portal is not installed.

     ```
     python3 create_secrets_in_target.py -n NAMESPACE
     ```

   - If both Management and Portal are in different namespaces:

     ```
     python3 create_secrets_in_target.py -mgmt_ns <MGMT_NAMESPACE> -ptl_ns <PTL_NAMESPACE>
     ```

   - If you are creating multiple Portal subsystems in the target API Connect system, to match the configuration of the source system, you must run the script more than once for each Portal subsystem from the source system.
     The script detects that there are two Portal subsystems in the source system, and prompts you to select the subsystem name that matches the target Portal, as shown in the following commands:

     - For Management and first Portal on the target system:

       ```
       python3 create_secrets_in_target.py -mgmt_ns <MGMT_NAMESPACE> -ptl_ns <PTL_NAMESPACE1>
       ```

     - For the second Portal on the target system:

       ```
       python3 create_secrets_in_target.py -skip_mgmt -ptl_ns <PTL_NAMESPACE2>
       ```

4. If applicable to your deployment, shutdown the Postgres database on your source system.
   You can shutdown the Postgres database now, to ensure that there are no delta changes to your source system while the remainder of the migration process takes place.

5. Launch the target API Connect system.
   a. Review prerequisites:
      - Have a new OpenShift cluster ready with enough resources (CPU, memory, and disk) as required for the installation profile you will use.
      - As needed, create an entitlement key to download the images related to API Connect.
      - The target system must match the topology (number of Gateways, Portals and Analytics) of the source system to ensure that all the data in the Management database is migrated. If all the data in the Management database is not migrated, the not migrated (stale) data must be manually deleted. Alternatively, you can attempt the remaining migration later after installing the additional Portals and Gateways. See v10 migration planning.

   b. Launch the target API Connect system either manually or by using the **install_apic_on_ocp.py** script:

      - To manually launch from the OpenShift cluster UI:

        This method is the recommended way to launch the target API Connect system for production systems.

        This method is also used for advanced customization or when using custom certificates while launching the target API Connect system.

        - Install and launch the target API Connect cluster. See the instructions for your deployment type:
          - API Connect on OpenShift: Deploying on OpenShift and Cloud Pak for Integration
          - Cloud Pak for Integration: Installation procedures with IBM Cloud Pak for Integration
        - Before creating the top level CR, use the yaml view to add the properties which you saved from the source system configuration.
          For the Management subsystem, the saved configuration is in **data/config.yaml**. For the Portal subsystem, the saved configuration is in **data/config_portal.yaml**.

          Important: If you do not use the configuration from the source system, the migration fails.
          - Management subsystem properties:
            - encryptionSecret
            - Management subsystem name
            - site name
            - database backup credentials
            - custom application credentials
            - originalUID
          - Portal subsystem properties:
            - encryptionSecret
            - site name
            - database backup credentials
            - originalUID

          Note: If target system is Kubernetes, the properties must be in the Management and Portal subsystem CRs.
        - The top level CR must look like the following example. The values for this top CR are from the generated artifacts (data/config.yaml and data/config_portal.yaml) after running Preparing the source system. Note that the example shows a value for **spec.management.name**. You can obtain this value from config.yaml.

  storageClassName: rook-ceph-block
  version: 10.0.8.0
```

    - You can also use the script **`install_apic_on_ocp.py`** with **`-no_install`** flag to generate the top level CR yaml, and use the yaml in the OpenShift UI and customize further.
- To launch using the **`install_apic_on_ocp.py`** script:
  The script is used to launch API Connect on OpenShift or API Connect with Cloud Pak for Integration using a top level CR that specifies one of each subsystem type:
    - Management
    - Developer Portal
    - Analytics
    - API Gateway

  Prerequisite:
    - The OpenShift cluster must be ready, and accessible using **`oc`**.
    - **Important:** The script is used to launch **ONLY** the specific version of API Connect based on the downloaded version of the artifacts.

  Usage:

    - Run the script with **`--help`** option to show additional flags available like **`-production and -profile`**.
    - License use is set to **`nonproduction`** by default unless the flag **`-production`** is used while running this script.
    - The profile defaults to the one replica profile **`n1xc7.m48`**, to specify a different profile use the **`-profile`** flag. For details of the available profiles, see API Connect deployment profiles for OpenShift and Cloud Pak for Integration. The one replica profile deploys 1 replica of each pod and is only for light, non-critical workloads such as basic development and testing.
    - Optionally, you can use the **`-no_install`** flag if you want to generate the yaml files (top level CR and other files needed in installation) without installing. In the following example commands, add the **`-no_install`** flag to the existing command parameters. You can use this top level CR from the OpenShift UI, and create an API Connect cluster.
    - Note : If CP4I environment, check if configurator job is completed and also check the output of:

      `oc get apiconnectcluster -n NAMESPACE`

Example command invocations:

Note: Each of the example commands includes parameters for a three replica profile deployment: `-production -profile n3xc16.m48`. If you have a one replica profile, omit these parameters.

- API Connect on OpenShift:
  - If the apiconnect and DataPower operators must be installed in all namespaces:

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE -n NAMESPACE -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME -production -profile n3xc16.m48
    ```

  - If the apiconnect and DataPower operators must be installed in a specific namespace:

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE -n NAMESPACE  -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME  -operator_in_specific_namespace -production -profile n3xc16.m48
    ```

- API Connect in Cloud Pak for Integration:
  - If operators are in all namespaces:

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME1 -cp4i -production -profile n3xc16.m48
    ```

  - If operators are in a specific namespace:

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME1 -cp4i -operator_in_specific_namespace -production -profile n3xc16.m48
    ```

  - If operators are in all namespaces, with additional flags `-production` (for license to be set to production) and `-profile` (using n3 profile in this example):

    ```
    python3 install_apic_on_ocp.py -license LICENSE_VALUE1 -n NAMESPACE -name topCRName -storageclass_apic
    STORAGE_CLASS_NAME1 -cp4i -production -profile n3xc16.m48
    ```

6. Optional: Install any additional Gateways, Developer Portals, or Analytics subsystems that are needed.
   - Complete this step now if your target system will have additional Gateways, Developer Portals, or Analytics subsystems to match what is there in the source API Connect system, and you want to complete data migration for all subsystems in one pass through the procedures in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
   - Skip this step now, and proceed to step 7 if either of the following cases are true:
     - If your target system will not need any additional Gateways, Developer Portals, or Analytics subsystems.
     - Your target system will have additional Gateways, Developer Portals, or Analytics subsystems but you want to first complete data migration based on the top CR installation (1 Management, 1 Portal, 1 Gateway, 1 Analytics), before you install any additional subsystems.

   Note: To review the data migration choices, see v10 migration planning.
   If you choose complete this step now, see:

   - Deploying on OpenShift and Cloud Pak for Integration
   - Installation procedures with IBM Cloud Pak for Integration
7. Next, restore the configuration from the source system. Continue with Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

Installing the target system on VMware

Create the project directory, configure you target deployment, create the ISO files, and deploy your VMs.

Form factor migration to VMware is supported only from a VMware environment. You cannot migrate a Kubernetes or OpenShift API Connect deployment to VMware.

When you install the target system, before you create the ISO files that are used in the OVA deployment, you must set some of the subsystem properties of your target system to the same values as your source system. Refer to the data directory that you created in Preparing the source system to find these values.

Other subsystem properties can be set to different values from your source subsystem. For example, the API endpoints such as **portal-www** and **platform-api**. Changing API endpoints is the typical use-case of a VMware to VMware migration.

Management subsystem

Follow the usual steps for configuring your management subsystem deployment: Preparing the management subsystem for deployment, but set the following properties to the same values as your source system.

1. Subsystem name.

   ```
   apicup subsys create <management subsystem name> management
   ```

   where *<management subsystem name>* is the same as your source system.

2. Encryption secret.

   ```
   apicup certs set <management subsystem name> encryption-secret --encoded-string <v10 source mgmt encryption secret>
   ```

   where *<v10 source mgmt encryption secret>* is found in data/*<management subsystem name>*/encryption-secret-*.yaml

3. Site name.

   ```
   apicup certs set management site-name=`<site name>`
   ```

4. Credential secrets.

   ```
   apicup certs set <management subsystem name> atm-credential --encoded-string '<encoded string>'
   apicup certs set <management subsystem name> consumer-toolkit-credential --encoded-string '<encoded string>'
   apicup certs set <management subsystem name> designer-credential --encoded-string '<encoded string>'
   apicup certs set <management subsystem name> toolkit-credential --encoded-string '<encoded string>'
   apicup certs set <management subsystem name> juhu-credential --encoded-string '<encoded string>'
   apicup certs set <management subsystem name> consumer-ui-credential --encoded-string '<encoded string>'
   ```

```
apicup certs set <management subsystem name> ui-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> discovery-credential --encoded-string '<encoded string>'
apicup certs set <management subsystem name> governance-credential --encoded-string '<encoded string>'
```

where *<encoded string>* is found in the corresponding secret YAML file in data/*<management subsystem name>*. For example:

```
<management subsystem name>-atm-cred.yaml
<management subsystem name>-ccli-cred.yaml
<management subsystem name>-cli-cred.yaml
<management subsystem name>-cui-cred.yaml
<management subsystem name>-dsgr-cred.yaml
<management subsystem name>-juhu-cred.yaml
<management subsystem name>-ui-cred.yaml
```

The encoded string is stored in `credential.json` property of each file:

```
apiVersion: v1
data:
  credential.json:
eyAiaWQiOiAiMzhmMzRjOTktODFhNC00NWFkLWFkOTgtMGM1MGFjN2YzYmJjIiwgInNlY3JldCI6ICI3OTIxYzE5Yi1jNWUwLTRhYzQtYTkyZC1iZjNmYWJlZWEwNDIiIH0=
kind: Secret
...
```

5. You can use the same management database backup configuration as your source system, or you can specify a new configuration.

Portal subsystem

Follow the usual steps for configuring your portal subsystem deployment: Preparing the portal subsystem for deployment, but set the following properties to the same values as your source system.

1. Subsystem name.

   ```
   apicup subsys create <portal subsystem name> portal
   ```

   where *<portalsubsystem name>* is the same as your source system.

2. Encryption secret.

   ```
   apicup certs set <portal subsystem name> encryption-secret --encoded-string <v10 source ptl encryption secret>
   ```

   where *<v10 source ptl encryption secret>* is found in data/*<ptl subsystem name>*/portal-encryption-secret-*.yaml

3. Site name.

   ```
   apicup certs set <portal subsystem name> site-name <v10 source ptl site name>
   ```

   where *<v10 source ptl site name>* is found in data/*<ptl subsystem name>*/config.yaml

4. Backup configuration.
   Use the same backup configuration as your source system to restore your portal sites.

Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

Restore the saved configuration and backups from the source system onto the target system.

Before you begin

- Complete Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Ensure that any network route between the target installation and the source system is disabled. The target system must not be able to communicate with the source system.

About this task

Use scripts to:

- Restore the Management subsystem
- Register Gateways and Portals on the target system
- Update Portals in the Catalog to point to new Portal systems
- Restore Portal backups for each site
- Update Gateways in the Catalog to point to new Gateway systems

All scripts run on the target system must be run from a location where the data directory is present so that the source configuration can be used.

Note: You can optionally run scripts in `--silent` mode, particularly for the following scenarios:

- Register Gateways and Portals in the target system. (Step 3)
- Update Portals in the Catalog to point to new Portal systems. (Step 4)
- Update Gateways in the Catalog to point to new Gateway systems. (Step 6)

If there are multiple Portals and Management subsystems present in the data directory (as saved during Preparing the source system), the restore script prompts you to select the subystem name to use for migration while running the script. If running in silent mode, that value must be supplied as an additional flag.

Deployments with multiple Portals and Gateways are a common scenario. The saved data can have multiple Management subsystems only if you ran **save_v10_source_configuration.py** against multiple clusters with different Management subsystem names, without cleaning the data directory.

Procedure

1. Before restoring the Management subsystem backup, determine whether there have been any delta changes to your source system since you backed up the Management subsystem database and Portal database.
   - If you shutdown the Postgres database, as instructed in Installing the target system on Kubernetes, OpenShift, and Cloud Pak for Integration, there are no delta changes. Continue to step 2.
   - If you did not shutdown the Postgres database, there could be some delta changes to the Management database, because the Management subsystem on the source system remains in READY state. In this case, to ensure you capture the latest configuration, repeat Preparing the source system. By doing so, the Management and Portal databases are backed up again. The latest backup will then be used to restore to the target system.
2. Restore a Management subsystem backup onto the target system.
   a. On the target API Connect system, ensure that the Management subsystem is up and running,
   b. Run **restore_management_db.py**. Examples:
      - OpenShift or Kubernetes target system:

        ```
        python3 restore_management_db.py -n <mgmt namespace>
        ```

        or:

        ```
        python3 restore_management_db.py -mgmt_ns <mgmt namespace>
        ```

      - Cloud Pak for Integration target system:

        ```
        python3 restore_management_db.py -n <namespace> -s <platform API hostname>
        ```

      - If for some reason the management subsystem is not healthy, restore using the command:

        ```
        python3 restore_management_db.py -n <mgmt namespace> -ignore_health_check
        ```

3. Register Gateways and Portals on the target system.
   a. Prerequisites:
      - The **register_gateway_portals_in_target.py** script must be run on the target system after the Management database from the source system has been restored.
      - The Gateway and Developer Portal subsystems that need to be registered must be in a healthy state.
   b. Usage notes:
      - The credentials provided from this step will be same as the credentials used on the source system, because the Management database from the source system is restored.
      - Keep the endpoints ready for the new Gateway and Portal services so that they can be registered by running **register_gateway_portals_in_target.py**. To view endpoints, use **oc get routes**.
      - If you run **register_gateway_portals_in_target.py** for a Cloud Pak for Integration target system, and you see the error **The API Connect Gateway Service is already registered to another API Manager instance**, restart all the gateway pods, wait for them to become healthy, and run **register_gateway_portals_in_target.py** again.
      - Make sure the mapping of old URLs with the new ones are correct. For example, when the source system is a VMware appliance, if wrongly mapped (wrong values provided) communication errors occur during Gateway registration. Example errors messages:

        - **"Error: An error occurred communicating with the gateways subsystem "**
        - **"error: 'Client network socket disconnected before secure TLS connection was established'"**

        On the appliance, the Gateway Manager URL uses port **3000**.

   c. Run **register_gateway_portals_in_target.py** in either interactive mode or silent mode:

      - Interactive mode
        The **register_gateway_portals_in_target.py** script displays the Portal and Gateway endpoints from the source system, and prompts the user to enter the corresponding values from the target system. Examples:

        - If Management, Portal and Gateway subsystems are in the same namespace:

          ```
          python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n <namespace>
          ```

        - If Management, Portal and Gateway subsystems are in different namespaces, use **-mgmt_ns**, **-ptl_ns**, and **-gw_ns** to specify each, for example:

          ```
          python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -gw_ns <gway namespace>
          ```

        - If you are using SSO authentication, replace:

          ```
          -u <username> -p <password>
          ```

          with:

          ```
          --sso
          ```

        - Multiple namespaces can alternatively be specified with **"ns1|ns2|ns3"** notation. For example:

          ```
          python3 register_gateway_portals_in_target.py -n "ns1|ns2|ns3" -u admin -p <password> -s <platform API hostname> -r admin/default-idp-1 -silent
          ```

          ```
          python3 register_gateway_portals_in_target.py -s <platform API hostname> -u admin -p <password> -r admin/default-idp-1 -mgmt_ns ns1 -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -silent
          ```

- Silent mode
  The gateway_portal_mapping.yaml file, with mapping between old and new endpoints for Gateway, Portal, and Analytics endpoints, must be located in the same directory as **register_gateway_portals_in_target.py**.

  This gateway_portal_mapping.yaml file is generated when saving the source API Connect system configuration with properties data filled in. For every Gateway, Portal, and Analytics subsystem registered with Management in the source system, the yaml has the endpoint mapping between source and target systems.

  Remaining data must be filled to use the yaml in silent mode. All values must begin with **https://**.

  - Example:

    ```
    python3 register_gateway_portals_in_target.py -n <namespace> -u <username> -p <password> -s <platform API hostname> -r <realm name> -silent
    ```

  - Example: If the subsystems are in multiple namespaces.
    For example, ns1, ns2, ns3 namespaces contain the subsystems. Both of the following commands work the same way:

    ```
    python3 register_gateway_portals_in_target.py -n "ns1|ns2|ns3" -u <username> -p <password> -s <platform API hostname> -r <realm name> -silent
    ```

    ```
    python3 register_gateway_portals_in_target.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns ns1 -ptl_ns "ns1|ns2" -gw_ns "ns1|ns2|ns3" -silent
    ```

  - Example gateway_portal_mapping.yaml file with:
    - Two Gateways
    - One Portal or Analytics subsystem
    - All data mapped to the target API Connect system:

    ```
    analytics_mapping:
      registered_analytics_name:
        https://ac.source-apic.example.com: https://a1-a7s-ac-endpoint-apic1.apps.vlxocp-3278.cp.fyre.example.com
    gateway_mapping:
      registered_apigw_name:
        https://rgw.source-apic.fyre.example.com: https://a1-gw-gateway-apic1.apps.vlxocp-3278.cp.fyre.example.com
        https://rgwd.source-apic.fyre.example.com: https://a1-gw-gateway-manager-apic1.apps.vlxocp-3278.cp.fyre.example.com
      registered_v5gw_name:
        https://gw.source-apic.fyre.example.com: https://v5gw.gw.apps.vlxocp-3278.cp.fyre.example.com
        https://gwd.source-apic.fyre.example.com: https://v5gw.gwd.apps.vlxocp-3278.cp.fyre.example.com
    portal_mapping:
      registered_portal_name:
        https://api.portal.source-apic.fyre.example.com: https://a1-ptl-portal-director-apic1.apps.vlxocp-3278.cp.fyre.example.com
        https://portal.source-apic.fyre.example.com: https://a1-ptl-portal-web-apic1.apps.vlxocp-3278.cp.fyre.example.com
    ```

  - Example gateway_portal_mapping.yaml file with:
    - Only two Gateways
    - One Portal or Analytics
    - One Gateway not mapped
      Note that "not mapped" means that the data in the Management subsystem related to this Gateway is not mapped, and the Gateway will not be migrated during this migration phase.

      The Gateway could be migrated later; for example, after the second Gateway is created on the target system. Until the data related to the not-migrated Gateway or Portal is migrated or deleted, there will be stale data in the database.

      The same behavior can be achieved by leaving the values empty, or removing the entire section (name and mapping).

    ```
    analytics_mapping:
      registered_analytics_name:
        https://ac.source-apic.example.com: https://a1-a7s-ac-endpoint-apic1.apps.vlxocp-3278.cp.fyre.example.com
    gateway_mapping:
      registered_apigw_name:
        https://rgw.source-apic.fyre.example.com: https://a1-gw-gateway-apic1.apps.vlxocp-3278.cp.fyre.example.com
        https://rgwd.source-apic.fyre.example.com: https://a1-gw-gateway-manager-apic1.apps.vlxocp-3278.cp.fyre.example.com
      registered_v5gw_name:
        https://gw.source-apic.fyre.example.com: NEW_GATEWAY_API_ENDPOINT_BASE_IN_TARGET_SYSTEM
        https://gwd.source-apic.fyre.example.com: NEW_GATEWAY_ENDPOINT_IN_TARGET_SYSTEM
    portal_mapping:
      registered_portal_name:
        https://api.portal.source-apic.fyre.example.com: https://a1-ptl-portal-director-apic1.apps.vlxocp-3278.cp.fyre.example.com
        https://portal.source-apic.fyre.example.com: https://a1-ptl-portal-web-apic1.apps.vlxocp-3278.cp.fyre.example.com
    ```

4. Use **update_to_new_portals.py** to update Portals in the catalog to point to new Portal systems.
   Note:
   If there is no Portal subsystem on the source system, skip this step. Also, skip this step if no Portal sites are created in any of the provider orgs. Continue with 6.

   If there is no change in your portal endpoints, then include the flag **-dont_use_toolkit_for_portal_backup** when you run the **update_to_new_portals.py** script.

   a. Review prerequisites:
      - The Management and Portal subsystems on the target API Connect system must be in a healthy state.
      - The **update_to_new_portals.py** script must be run on the target system after the following actions have been completed:

- The Management database from the source system has been restored.
- The new Gateway or Portal instance is registered in the Cloud Manager, using script or from the UI.

- The credentials for accessing the admin org (Cloud Manager UI) and, if required, the provider org (API Manager UI) must be available for running the script.

b. Run the **update_to_new_portals.py** script in one of two modes, based on how the Provide Org credentials are available. The modes are:

- Using a common migration user created by the script
- Using credentials provided by the user in a yaml file

Important: The provider org credentials must have administrative access.

Examples:

- Using a common migration user created by the script :
  The **update_to_new_portals.py** script runs in this mode by default. This script creates a migration user **muser1** in **migrationur** local user registry, and uses it to migrate Portal information in all the provider orgs. Once the migration is done, the user and user registry are deleted. There is no change in data once the migration is complete.

  Examples:

  - If the Management and Portal subsystems are in the same namespace

    ```
    python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -n
    <namespace> -api_manager_hostname <platform API hostname>  -silent
    ```

  - If using SSO authentication:

    ```
    python3 update_to_new_portals.py -s <platform API hostname> --sso -n <namespace> -api_manager_hostname
    API_MANAGER_HOSTNAME -silent
    ```

  - If the Management and Portal subsystems are in different namespaces:

    ```
    python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns
    <mgmt namespace> -ptl_ns <portal namespace>E -api_manager_hostname <platform API hostname>E -silent
    ```

- Using credentials provided by the user in a **provider_org_credentials.yaml** file:
  The **provider_org_credentials.yaml** file, with some data filled in, is generated by the **save_v10_source_configuration.py** script you ran in Preparing the source system. The yaml file is available in the same directory as the script. The script has to be edited and all details filled in before it can be used.

  Examples:

  - If Management and Portal subsystems are in the same namespace:

    ```
    python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -n
    <namespace> -no_migration_user -silent
    ```

  - If using SSO authentication:

    ```
    python3 update_to_new_portals.py -s <platform API hostname> --sso -n <namespace> -no_migration_user -silent
    ```

  - If Management and Portal subsystems are in different namespaces:

    ```
    python3 update_to_new_portals.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -
    mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -no_migration_user -silent
    ```

  Example provider_org_credentials.yaml:

  - With credentials given for every provider org. In this example, only two orgs are present.

    ```
    provider_org_credentials:
      apiManagerHostName: <platform API hostname>
      PORG_NAME_1:
        password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
        realm: provider/default-idp-2
        username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
      PORG_NAME_2:
        password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
        realm: provider/default-idp-2
        username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
      useSameCredentialsForAllProviderOrgs: false
    ```

  - With credentials given for just one provider org. Also requires **useSameCredentialsForAllProviderOrgs** set to true. This method can be used only when the same credentials are used for all provider orgs.
    Note: In some cases, there are multiple provider orgs in the Management database.

    ```
    provider_org_credentials:
      apiManagerHostName: <platform API hostname>
      PORG_NAME_1:
        password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
        realm: provider/default-idp-2
        username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
      useSameCredentialsForAllProviderOrgs: true
    ```

  - With SSO credentials and just one provider org:

    ```
    provider_org_credentials:
      apiManagerHostName: <platform API hostname>
      useSameCredentialsForAllProviderOrgs: false
      porg_anme:
        #sso authentication
        #the key(that can expire in sometime) has to be generated separately using
    https://<apiManagerHostname>/auth/manager/sign-in/?from=TOOLKIT
        apiKey: some_key
    ```

5. Restore Portal backups for each site.
   Note:
   If there is no Portal subsystem on the source system, skip this step. Continue with 6.

   If there is no change in your portal endpoints, then include the flag **-s <platform API hostname>** when you run the **restore_portal_db.py** script.

   To restore the Portal sites on the target system, you can either use the using script restore_portal_db.py or complete a manual restore.

   - Restoring through the script:

     ```
     python3 restore_portal_db.py -n PORTAL_SUBSYSTEM_NAMESPACE
     ```

   - Restoring through manual steps:
     - Log in to the Portal admin container:

       ```
       oc exec -it <www_pod> -c admin -- bash
       ```

     - List the site backups:

       ```
       remote_transfer_backup -l
       ```

       The list of backups that need to be restored is available in the output logs as a report of Step 4.

     - Download each site backup, and run it for all sites:

       ```
       remote_transfer_backup -d <SITE_BACKUP_FILENAME>
       ```

     - Restore each of the site backups:

       ```
       restore_site -f -u <SITE_URL> <SITE_BACKUP_FILENAME>
       ```

   Note: If there are more than one Portal subsystems on the target system, as needed to correspond to the Portal subsystems on the source system, run the script for each of the matching source and target Portal subsystems.
   For example, if there are two Portals on the target system, matching what is on the source system, and these Portals are installed in namespaces **target1** (for the top-level CR) and **ptl2** (for second portal), then the script will be run twice, as follows:

   ```
   python3 restore_portal_db.py -n target1
   ```

   ```
   python3 restore_portal_db.py -n ptl2
   ```

6. Run **update_to_new_gateways.py** to update Gateways in the Catalog to point to new Gateway systems.
   a. Review prerequisites:
      - The Gateway subsystem must be in a healthy state.
      - The **update_to_new_gateways.py** script must be run on the target system after the following actions have been completed:
        - The Management database from the source system has been restored.
        - The new Gateway instance is registered in the Cloud Manager, using script or from the UI.
      - The credentials for accessing the admin org (Cloud Manager UI) and, if required, the provider org (API Manager UI) must be available for running the script.

   b. Run the **update_to_new_gateways.py** script in one of two modes, based on how the Provider Org credentials are available. The modes are:
      - Using a common migration user created by the script
      - Using credentials provided by the user in a yaml file

      Important: The provider org credentials must have administrative access.
      - Using a common migration user created by the script:
        The **update_to_new_gateways.py** script runs in this mode by default. This script creates a migration user **muser1** in **migrationur** local user registry, and uses it to migrate Portal information in all the provider orgs. Once the migration is done, the user and user registry are deleted. There is no change in data once the migration is complete.

        Examples:

        - If the Management and Gateway subsystems are in the same namespace:

          ```
          python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -n <namespace> -api_manager_hostname <platform API hostname>  -silent
          ```

        - If using SSO authentication:

          ```
          python3 update_to_new_gateways.py -s <platform API hostname> --sso -n <namespace> -api_manager_hostname <platform API hostname> -silent
          ```

        - If the Management and Gateway subsystems are in different namespaces:

          ```
          python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -mgmt_ns <mgmt namespace> -ptl_ns <portal namespace> -api_manager_hostname <platform API hostname> -silent
          ```

      - Using credentials provided by the user in a **provider_org_credentials.yaml** file:
        The **provider_org_credentials.yaml** file, with some data filled in, is generated by the **save_v10_source_configuration.py** script you ran in Preparing the source system. The yaml file is available in the same directory as the script. The script has to be edited and all details filled in before it can be used.

        - If the Management and Gateway subsystems are in the same namespace:

          ```
          python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name>  -n <namespace> -no_migration_user -silent
          ```

        - If using SSO authentication:

          ```
          python3 update_to_new_gateways.py -s <platform API hostname> --sso -n <namespace> -no_migration_user -silent
          ```

- If the Management and Gateway subsystems are in different namespaces:
  Note that if multiple gateway subsystems present across namespaces, you can give multiple namespaces separated by the "|" symbol for `-gw_ns`.

  ```
  python3 update_to_new_gateways.py -s <platform API hostname> -u <username> -p <password> -r <realm name> -mgmt_ns <mgmt namespace> -gw_ns GW_NAMESPACE -no_migration_user -silent
  ```

- Example provider_org_credentials.yaml
  - With credentials given for every provider org, and only two orgs present:

    ```
    provider_org_credentials:
      apiManagerHostName: <platform API hostname>
      PORG_NAME_1:
        password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
        realm: provider/default-idp-2
        username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
      PORG_NAME_2:
        password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
        realm: provider/default-idp-2
        username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
      useSameCredentialsForAllProviderOrgs: false
    ```

  - With credentials given for just one provider org, and `useSameCredentialsForAllProviderOrgs` is set to `true`.
    This can be used only when same credentials are used for all provider orgs.

    Note: There can be multiple provider orgs in the Management database.

    ```
    provider_org_credentials:
      apiManagerHostName: <platform API hostname>
      PORG_NAME_1:
        password: PASSWORD_FOR_THIS_REALM_TO_BE_CHANGED
        realm: provider/default-idp-2
        username: USERNAME_FOR_THIS_REALM_TO_BE_CHANGED
      useSameCredentialsForAllProviderOrgs: true
    ```

  - With SSO credentials and just one provider org:

    ```
    provider_org_credentials:
      apiManagerHostName: <platform API hostname>
      useSameCredentialsForAllProviderOrgs: false
      porg_anme:
        #sso authentication
        #the key(that can expire in sometime) has to be generated separately using
    https://<apiManagerHostname>/auth/manager/sign-in/?from=TOOLKIT
        apiKey: some_key
    ```

7. Continue to Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

Restoring the target system on VMware

Restore the saved configuration and backups from the source system onto the target system.

Restoring the management subsystem

1. Copy the toolkit CLI apic executable to your FFM directory. See Installing the toolkit. Ensure that your toolkit CLI version matches the API Connect version of your target management VM.
   You created the FFM directory in Preparing the source system. The FFM directory contains Python scripts, YAML files, and a data directory that contains your exported source system data.
2. Login to your target management VM with SSH, and switch to the root user:

   ```
   ssh apicadm@<management hostname>
   ```

   ```
   sudo -i
   ```

   If you deployed a three replica management profile, then login to just one of the VMs.
3. Copy the FFM directory to your target management VM.
4. Ensure that the FFM directory is set first in your `PATH` variable:

   ```
   export PATH=<FFM directory>:$PATH
   ```

   Note: The API Connect VMs have an executable that is called apic in the `PATH` variable. The toolkit CLI apic must come before it in the `PATH` so that the restore scripts run correctly.
5. Run the management database restore script:

   ```
   python3 restore_management_db.py -n default
   ```

   Tip: To get help information with the restore scripts, run them with the flag `--help`.

   ```
   python3 <script name> --help
   ```

   The script output shows the progress and when the restore is complete.
6. Edit the gateway_portal_mapping.yaml file and set the endpoints on right side of the file to the endpoints defined for your target VM. The endpoint values can be obtained from the apiconnect-up-v10.yml file in your project directory.
7. Run the register gateway and portals script:

```
python3 register_gateway_portals_in_target.py -s <platform API endpoint> -u admin -p <password> -r admin/default-idp-1 -n default -silent
```

where
- *<platform API endpoint>* is defined in the apiconnect-up-v10.yml file in your project directory.
- *<password>* is the admin password that is used on your source system.

8. Run the update portals script:

```
python3 update_to_new_portals.py -s <platform API endpoint> -u admin -p <password> -r admin/default-idp-1 -n default -api_manager_hostname <platform API endpoint> -silent
```

9. Run the update gateways script:

```
python3 update_to_new_gateways.py -s <platform API endpoint> -u admin -p <password> -r admin/default-idp-1 -n default -api_manager_hostname <platform API endpoint> -silent
```

Restoring the portal subsystem

1. Login to your target portal VM with SSH, and switch to the root user:

```
ssh apicadm@<portal hostname>
```

```
sudo -i
```

If you deployed a three replica portal profile, then login to just one of the VMs.

2. Copy the FFM directory from the management VM to your portal VM.
3. Ensure that the FFM directory is set first in your `PATH` variable:

```
export PATH=<FFM directory>:$PATH
```

Note: The API Connect VMs have an executable that is called apic in the `PATH` variable. The toolkit CLI apic must come before it in the `PATH` so that the restore scripts run correctly.

4. Run the restore portal sites script:

```
python3 restore_portal_db.py -n default
```

Verifying the target system on Kubernetes, OpenShift, and Cloud Pak for Integration

Verify that the target system is in a healthy state and fully configured.

Before you begin

Complete Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

About this task

Check the health of the target system, complete any optional configuration, and validate data, APIs, and URLs.

Procedure

1. Use the `health_check_post_migration.py` script to health check the target system.
Examples:

- When all the subsystems are in the same namespace, and the deployments uses username/password authentication:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -n NAMESPACE
```

- When all the subsystems are in the same namespace, and the deployments uses username/password authentication, with use of the optional flag `–check_portal_site_health` to check the health of Portal sites:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD  -n NAMESPACE -check_portal_site_health
```

- When subsystems are present in different namespaces, and the deployment uses username/password authentication

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD  -mgmt_ns NAMESPACE -gw_ns NAMESPACE
```

- When all subsystems are in different namespaces, and the deployment uses username/password authentication:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD  -mgmt_ns NAMESPACE -gw_ns NAMESPACE -ptl_s NAMESPACE -a7s_ns NAMESPACE
```

- When all subsystems are in the same namespace, and the deployment uses SSO authentication:

```
python3 health_check_post_migration.py -n NAMESPACE --sso -s PLATFORM_API_HOSTNAME
```

- When all subsystems are in the same namespace, and the deployment uses SSO authentication silent mode:

```
python3 health_check_post_migration.py -n NAMESPACE --sso -s PLATFORM_API_HOSTNAME -api_key API_KEY_VALUE
```

- When there are multiple subsystems across namespaces:

```
python3 health_check_post_migration.py -s PLATFORM_API_HOSTNAME -r REALM_NAME -u USERNAME -p PASSWORD -n
"namespace1|namespace2|namespace3"
```

2. Complete any optional configuration steps needed for your deployment:
   a. If necessary, update redirect URLS in the authorization server.
      If OIDC or SSO authentication is being used, the redirect URLS must be updated in the authorization server after migration. For example, for Google OIDC, you must to add the new redirect URLs in Google Developer Console. The new redirect URLs can be found in the user registry in Cloud Manager.

   b. If necessary, complete configuration for Analytics.
      If the Analytics service is present on the target system, backups must be configured. Also, use the Cloud Manager UI to manually associate the Analytics with the Gateways, as needed.

   c. If the target system is Cloud Pak for Integration, you must use the password from the target API Connect system to log in to Platform Navigator.
   d. If necessary, update Portal and Gateway services names in scripts or utilities.
      The migrated Portal and Gateway services will have new names (old_name + "new"). Any scripts and utilities written using the apic toolkit must be updated if they are using names as input parameter and not the ids. This is applicable to only Portal and Gateway names.

3. Validate configuration data:
   a. Validate the data in the target API Connect system by logging into Cloud Manager and API Manager UIs.
   b. Validate the APIs published in the Gateways.
   c. Validate the Portal site URLs
   d. If necessary, update the DNS mapping info.
      Once all of the APIs are verified, you may need to update the DNS mapping info, to redirect the calls to the new Gateways and Portals.

   The v10 migration is now complete.

4. After migration is finished, and verification of the target system is complete, you can uninstall API Connect on the source system.
   See Uninstalling API Connect.

Verifying the target system on VMware

Verify that the target system is in a healthy state and fully configured.

Before you begin

Complete Restoring the target system on VMware.

About this task

Check the health of the target system, complete any optional configuration, and validate data, APIs, and URLs.

Procedure

1. Login to your target management VM with **SSH**, and switch to the root user:

   ```
   ssh apicadm@<management hostname>
   ```

   ```
   sudo -i
   ```

   If you deployed a three replica management profile, then login to just one of the VMs.
2. Run the health check script:

   ```
   python3 health_check_post_migration.py -s <platform API endpoint> -u admin -p <password> -r admin/default-idp-1 -n default
   ```

   where
   - *<platform API endpoint>* is defined in the apiconnect-up-v10.yml file in your project directory.
   - *<password>* is the admin password that is used on your source system.

Migrating from OpenShift to Cloud Pak for Integration on the same cluster

Migrate your API Connect v10 deployment from OpenShift to Cloud Pak for Integration, while remaining on the same cluster.

Before you begin

Your API Connect instance must use the top-level CR. Direct migration of individual API Connect subsystem installations to Cloud Pak for Integration by the steps described here is not supported. Alternative methods of migration if you are not using the top-level CR are:

- If the same subsystem endpoints can be used, deploy a new top-level CR API Connect and restore disaster recovery backups from your existing installation, see Backing up, restoring, and disaster recovery. The new top-level CR deployment can then be migrated to Cloud Pak for Integration following the steps here.
- If different subsystem endpoints need to be used, migrate your API Connect deployment to a new top-level CR OpenShift cluster first. Follow the form factor migration steps Migrating from v10 to v10 on a different form factor, and then return here to complete the OpenShift top-level CR to Cloud Pak for Integration migration.

About this task

Procedure

1. Update your `<TOP_CR_NAME>-mgmt-admin-pass` secret with your current Cloud Manager admin password:
   a. Check whether the `<TOP_CR_NAME>-mgmt-admin-pass` password already matches your Cloud Manager admin password with:

   ```
   oc get secret -n <APIC-namespace> | grep mgmt-admin-pass

   oc get secret -n <APIC-namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d &&
   echo ""
   ```

   If the passwords match then skip to 2.
   b. From where you run OpenShift CLI commands, use the base64 command to encode your Cloud Manager admin password.

   ```
   echo -n '<password>' | base64
   ```

   Note: If the `base64` command is not available, alternative commands or tools can be used.
   c. Edit the `<TOP_CR_NAME>-mgmt-admin-pass` secret:

   ```
   oc edit secret <TOP_CR_NAME>-mgmt-admin-pass -n <namespace>
   ```

   d. Replace the `data.password` value with your base64 encoded value from 1.b.

   ```
   ...
   data:
     email: ZXhhbXBsZUBleGFtcGxlLmNvbQ==
     password: <base64 encoded password>
   kind: Secret
   metadata:
   ...
   ```

   Note: The password in `<TOP_CR_NAME>-mgmt-admin-pass` is only used on API Connect installation, form factor migration, and disaster recovery. It does not need to be kept in sync with the Cloud Manager during normal API Connect usage.
2. Install IBM Cloud Pak Platform UI and create an instance of it.
3. Restart the `apiconnect` operator pod.
   The restarted operator pod detects Cloud Pak for Integration and reconciles the subsystems with it. Wait for the subsystems to be healthy.
4. Log in to Cloud Manager and check the services under the topology section.
   Known issue: If you see an additional Analytics service with a different name for the same Analytics endpoint, you must delete the newly created Analytics service.
5. Check that the configurator job is complete: :

   ```
   oc get pods -n <namespace>
   ...
   NAME                                                READY   STATUS      RESTARTS   AGE
   <instance name>-configurator-<random string>        0/1     Completed   0          2h
   ...
   ```

   Complete the following validation checks:
   - Verify you are able to login to the Cloud Pak for Integration Platform UI, and can see your API Connect instance.
   - Verify you are able to login to Cloud Manager UI, API Manager UI, and your portal sites.
   - Test that your APIs are running, and analytics data is logged.
   - Test lifecycle operations such as a product publish or delete, or an app creation.

v10 migration troubleshooting

Troubleshoot problems with v10 migration.

Topics:

- Script help
- Restarting migration
- Factory reset of portal subsystem
- Avoid error when a gateway is already registered to another API manager

Script help

```
python3 <SCRIPT_FILE_NAME> --help
```

Restarting migration

On the target system, after running `register_gateway_portals_in_target.py` or `update_to_new_portals.py` or `update_to_new_gateways.py` script:

- If you want to restore the Management database and try the steps again:
  - Run the restore Management db (Step 2 on Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration) with the `-reset_gateway_portal` flag as shown

    ```
    python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
    ```

    If running on a Kubernetes environment, supply the Cloud Manager admin password by using the `-p` flag. After this, continue with next steps of migration.
- If you deleted the data directory after registering Gateways or Portals, but want to use the same target API Connect system which you already installed, then:
  1. Complete Preparing the source system to create the data directory.
  2. Run the restore management db (Step 2 on Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration) with the `-reset_gateway_portal` flag as shown

```
python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
```

If running on a Kubernetes environment, supply the Cloud Manager admin password by using the `-p` flag. After this, continue with next steps of migration.

Factory reset of portal subsystem

You can do a factory reset of the Portal subsystem by either manually or by using a migration script.

- Using migration script
  The script will restore the Management database and will factory reset the Portal subsystem, and also delete Gateway pods. The gateway pods will get restarted.

  The script will factory reset the Portal subsystem and also delete Gateway pods. When Gateway pods are deleted, they are also restarted.

  ```
  python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
  ```

  If using a Kubernetes environment, you must also supply the Cloud Manager admin password by using the `-p` flag. After this command, you must run the remaining steps of migration, starting with Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.

  ```
  python3 register_gateway_portals_in_target.py -n NAMESPACE -u USERNAME -p PASSWORD -s HOSTNAME -r REALM_NAME -reset_gateway_portal
  ```

- **Manual steps**
  1. Log in to the Portal www pod:

     ```
     kubectl exec -it PORTAL_WWW_POD_NAME -c admin -n NAMESPACE -- bash
     ```

  2. Run the command :

     ```
     curl -X DELETE -k --cert /etc/nginx/ssl/portal-director-client-both.pem  https://localhost:3009/v2/portal/factory-reset
     ```

  3. If any sites are there, use the `list_sites` command to check if all sites are deleted.
  4. Check health of the Portal subsystem.

Avoid error when a gateway is already registered to another API manager

Error messages

```
Error: An error occurred communicating with the gateways subsystem at 'some_url' (status: 400, response: '"Unable to perform initial registration for API Management.
Error: The API Connect Gateway Service is already registered to another API Manager instance"
```

You can fix the error condition manually, or use a script:

- Manual step, when Gateway is in a Kubernetes or OpenShift cluster:
  Restart all the gateway pods.
- Using the migration script when Gateway is in a Kubernetes or OpenShift cluster:
  The script will restore the Management database, factory reset the Portal subsystem, and delete the Gateway pods. Once deleted, Gateway pods get restarted.
  1. Run the following script:

     ```
     python3 restore_management_db.py -n namespace -s PLATFORM_API_HOSTNAME -reset_gateway_portal
     ```

     If using a Kubernetes environment, you must also supply the Cloud Manager admin password by using the `-p` flag.

  2. After this command, you must run the remaining steps of migration, starting with Step 3 in Restoring the target system on Kubernetes, OpenShift, and Cloud Pak for Integration.
- Gateway is on an Appliance
  Reboot all the Gateway appliances.

The API Connect operations tool: apicops

Use the apicops operations tool to check the health, troubleshoot, and run maintenance operations on your API Connect installation.

The API Connect apicops tool is in active development and is available to download from github.com. It is available for Linux® and macOS. All suggestions, feedback, and bug reports can be raised in this repository.

Installing

Download the binary for your operating system from latest release. Rename the file to `apicops`, and give it execute permission: `chmod +x apicops`.

Running apicops

Apicops requires access to your Kubernetes or OpenShift environment. For more information about using apicops, see: Requirements for running apicops.

Using Config Sync to replicate consumer-side catalog data

Use the API Connect Config Sync utility to replicate consumer-side data from a source catalog in an API Connect cluster to a target catalog in a different API Connect cluster, so that API calls can be served by either API Connect cluster interchangeably to enable hybrid deployments and high-availability style scenarios.

Topic relocated to Using Config Sync to replicate consumer-side catalog data.

- **Downloading the Config Sync utility**
  Download and extract the API Connect Config Sync utility.
- **Running Config Sync as a standalone binary**
  The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.

Downloading the Config Sync utility

Download and extract the API Connect Config Sync utility.

Topic relocated to Downloading and extracting the API Connect Config Sync utility.

Running Config Sync as a standalone binary

The pre-built binaries allow you to run the API Connect Config Sync utility from a Mac, Windows, or Linux x86 platform.

Topic relocated to Running Config Sync as a standalone binary.

Configuring and managing your server environment

You configure and manage the servers that comprise your IBM® API Connect on-premises cloud by using the Cloud Manager user interface.

The Cloud Manager user interface is the part of IBM API Connect that enables a Cloud Administrator to define and manage the API Connect on-premises cloud.

You can use the Cloud Manager to define the API Connect cloud by performing the following tasks:

- Create Provider organizations and invite users to serve as the owner
- Create and manage user roles and role defaults
- Create availability zones for services
- Register the relevant servers that will provide the gateway, analytics, and portal services
- Associate an analytics service with a gateway to enable reports for API Events
- Configure resources for user authentication, TLS security, and OAuth providers and make the resources visible to all or selected provider organizations
- Connect to an existing SMTP mail server and edit templates for system-generated emails
- Set the default gateway service for catalogs

- **Cloud Manager configuration checklist**
  A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM API Connect, and further supplementary tasks.
- **Activating your Cloud Manager user account**
  If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.
- **Accessing the Cloud Manager user interface**
  How to navigate to and login to the Cloud Manager user interface.
- **Defining your Cloud Manager topology**
  To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. A default availability zone is provided with the installation.
- **Managing authentication and security**
  Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.
- **Configuring the cloud settings**
  Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.
- **Configuring governance in the Cloud Manager**
  How to add governance rulesets in the Cloud Manager to validate and enforce organizational governance policies and best practices across your API development process.
- **Administering provider organizations**
  Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.
- **Administering members and roles**
  Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.
- **Monitoring the cloud**
  API Connect generates events to monitor the status of your cloud.
- **Changing your Cloud Manager password and profile information**
  You can change your Cloud Manager password and update your profile information.
- **Resolving login problems by increasing HTTP header size**
  You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.
- **Onboarding a new admin for Cloud Pak for Integration**
  Use the API Connect toolkit CLI to create a new admin account for use with Cloud Pak for Integration.
- **Extending the Gateway server behavior**
  To support your enterprise requirements, you can extend the Gateway servers within IBM API Connect to provide extra enforcement behavior.

- **Cloud Manager Tutorials**
  Tutorials for using the Cloud Manager user interface in IBM API Connect.

Cloud Manager configuration checklist

A summary, with links, of the key initial configuration tasks that you must complete in the Cloud Manager user interface after installing and deploying IBM® API Connect, and further supplementary tasks.

Key initial tasks

Task	Description
Log in to the Cloud Manager user interface	A default admin user account is provided for you to begin your configuration tasks.
Configure an email server for notifications	The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service.
Specify your email server as the notification server	Select the email server to be used as the notification server, and configure the sender name and email address to be included in the emails.
Register a Gateway service	A Gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.
Register an Analytics service	The Analytics service collects API event data from the Gateway service.
Associate the Analytics service with a Gateway service	You must associate an Analytics service with each of the Gateway services from which you want to collect API event data.
Register a Portal service	The Portal service provides a developer portal used by application developers to discover APIs and onboard consumers.
Create a provider organization	For developers to be able to publish APIs, and for API managers to be able to manage the API lifecycle, they must be a member of a provider organization. You must create a least one provider organization specifying the owner, who can add further members.

Further supplementary tasks

Task	Description
Configure authentication and security	API Connect provides default local user registries, but you can configure your own user registries, of various types, for user interface and API access control. You can also configure TLS profiles for securing data transmission over HTTPS, and OAuth providers for securing third-party website or application access to APIs.
Create an Availability Zone	An Availability Zone is a logical grouping of one or more API Connect services. A default Availability Zone is provided on installation, but you can add further Availability Zones to reflect your data center topology.
Administer members and roles	You can add further users as members of the administration organization, and control their permissions by assigning predefined roles. You can also create your own custom roles.
Monitor your API Connect cloud	API Connect generates events to allow you to monitor the status of your cloud.

Activating your Cloud Manager user account

If you have been invited to be an administrator of your API Connect cloud, you must activate your account by using the activation link that was sent by another administrator. You can then access the Cloud Manager user interface.

Before you begin

A cloud administrator invited you to join API Connect .

Procedure

1. Complete the following steps to activate your Cloud Manager account:

   If the Identity Provider uses LDAP
   : An invitation email with an activation link is sent. Click the activation link, or paste it in a browser, to log in directly with your LDAP user credentials. Upon authentication, the API Connect user record is updated from the backend identity provider.

   If the Identity Provider uses a local registry
   : An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your first name, last name and password. Passwords must have a minimum of 8 characters and contain characters from at least three of the four following categories:
     - Uppercase letters

- Lowercase letters
- Numbers
- Special characters (for example: ! # $ %)

Note:

- The email address that you enter on the sign up page must match the email address to which the invitation email was sent, otherwise the account activation fails.
- If you previously had an account that was removed, and you are being invited again, you must re-activate your account by using the Sign In option on the page, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail.

If the Identity Provider uses an authentication URL

An invitation email with an activation link is sent. Click the activation link or paste it in a browser. The activation link takes you to a sign up page where you enter your credentials, which then become your user name and password. Upon authentication, the API Connect user record is updated from the backend identity provider.

If multiple user registries are available for selection on the sign up page, then make sure that the correct registry for your Cloud Manager account is selected. You might need to ask your administrator which user registry is appropriate for your account.

For information on configuring user registries and making them available for Cloud Manager login, see User registries overview and Selecting user registries for Cloud Manager and API Manager.

2. Click Sign up to complete your registration, then click Sign in to open the Cloud Manager login page.

Results

You have created your API Connect administrator account.

What to do next

Log in to the Cloud Manager user interface and, depending on your role, start to manage the cloud topology, and work with provider organizations and cloud resources. To access the Cloud Manager login page in the future, use the following URL:

`https://host/admin`

where *host* is the fully qualified host name or IP address of the Management server.

Related concepts

Accessing the Cloud Manager user interface

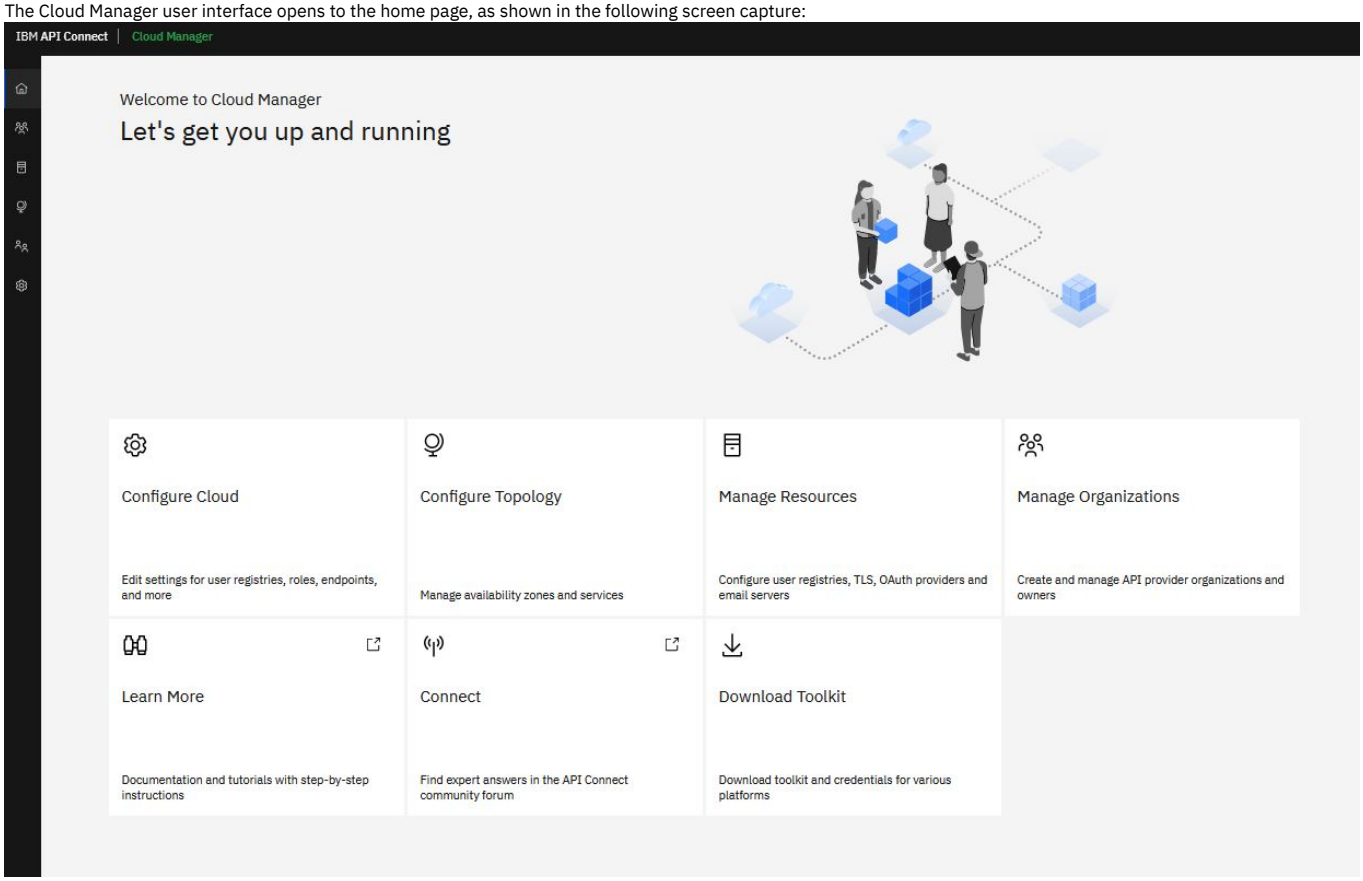
How to navigate to and login to the Cloud Manager user interface.

Procedure

1. Open a browser and enter the URL for the cloud-admin-ui endpoint followed by /admin. Note that this is a secure connection that uses HTTPs, for example: `https://<cloud-admin-ui>/admin`.
   - VMware installations: The cloud-admin-ui endpoint was set during installation of the Management subsystem by the following command: `apicup subsys set mgmt cloud-admin-ui <endpoint>`. Append `/admin` to this value.
   - Kubernetes, OpenShift, Cloud Pak for Integration installations: The cloud-admin-ui endpoint is specified in the Management subsystem CR, in the `Endpoints` section, for example:

     ```
     Endpoints:
       ...
       Name:   admin
       Type:   UI
       Uri:    https://example.com/admin
       ...
     ```

2. Enter the Cloud Administrator user name and password.
   - Kubernetes, VMware, and OpenShift individual Management subsystem install:
     If you are logging in for the first time, enter `admin` for the user name and `7iron-hide` for the password. Otherwise, enter `admin` for the user name and your own password.
   - OpenShift top-level CR install:
     The default user name is `admin`. If you are logging in for the first time, run the following commands to retrieve the initial password, which is generated automatically during deployment:



```
oc get secret -n <namespace> | grep mgmt-admin-pass

oc get secret -n <namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d && echo
""
```

3. If your cloud contains multiple user registries, as configured on the Settings > User Registries screen, then choose the user registry that contains your login credentials. You might need to ask your administrator which user registry is appropriate for your account.
4. Click Sign In.
   Important: The first time that you access the cloud console, you must, for security reasons, enter a new password and your email address. If you forget your password and request a password reset, the notification email is sent to this email address. The email is sent by the email server that is configured in the **Notifications** section of the cloud **Settings**.

Results

The Cloud Manager user interface opens to the home page, as shown in the following screen capture:

What to do next

Configure the email server so you can reset your password if needed and send other notifications. See Tutorial: Configuring the Cloud.

Configure your topology by registering services. See Tutorial: Configuring the Cloud.

Create a Provider Organization. See Tutorial: Creating a Provider Organization.

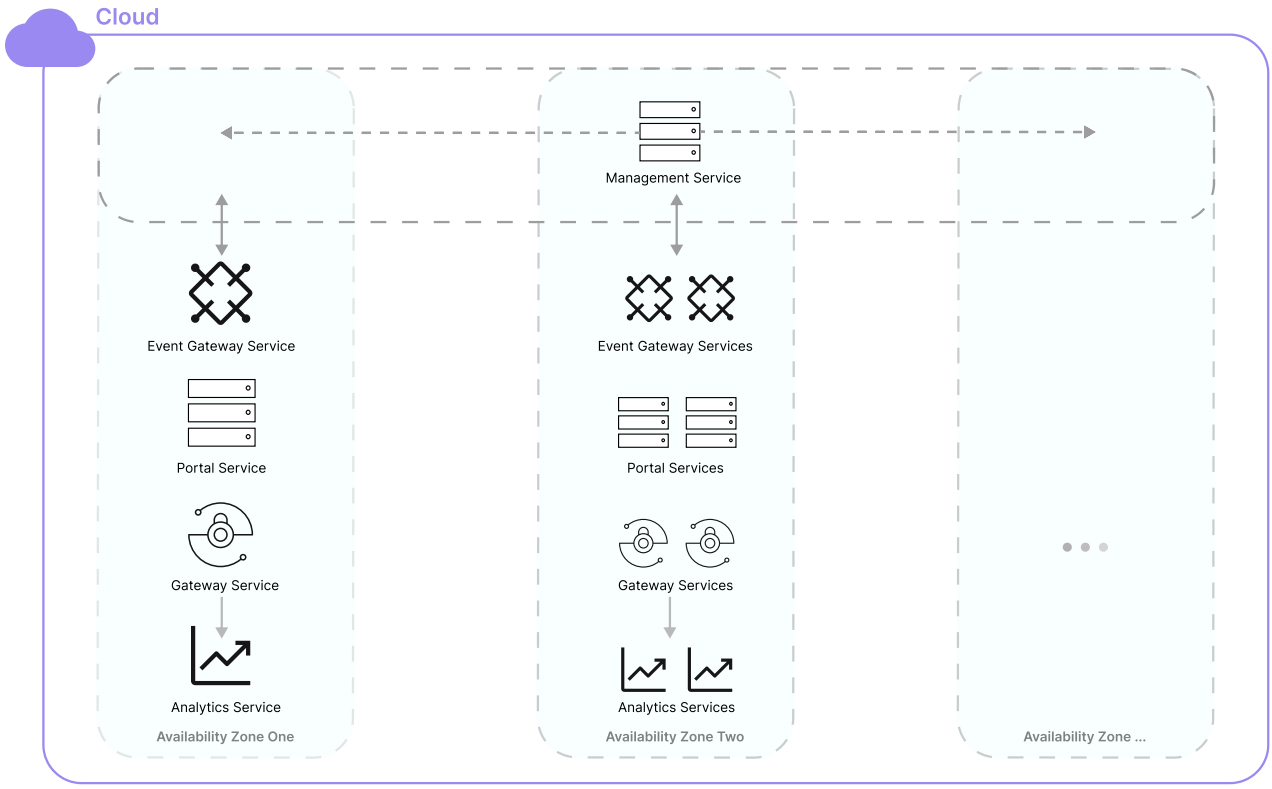
- Changing your Cloud Manager password and profile information



Defining your Cloud Manager topology

To define your API Connect on-premises cloud, you define availability zones and register services within those zones to securely create, promote, and track APIs. A default availability zone is provided with the installation.

About this task

The Cloud Manager topology consists of availability zones that contain the API Connect services. Availability zones can contain one or more DataPower gateway services, event gateway services, analytics services, and portal services.

The following diagram illustrates the topology for services and availability zones in an API Connect network:

One of the following roles is required to register and manage services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Following are the tasks involved in defining the API Connect topology:

- Create one or more availability zones.
- Register one or more DataPower gateway, event gateway, analytics, and portal services in each availability zone
- Associate an analytics service with each DataPower gateway service
- Set the visibility for the services

When the cloud is defined and an email server is configured, you can invite other users to access API Manager to create APIs. You then expose these APIs to the consumers (the development community) through the Developer Portal user interface.

To define the API Connect cloud, complete the following tasks:

- **Creating an availability zone**
  An Availability Zone is a logical group of one or more API Connect services. The Default Availability Zone is created during installation.
- **Registering a gateway service**
  A gateway service is required to handle incoming traffic for APIs.
- **Registering an event gateway service**
  Configure your IBM Event Endpoint Management instance (Manager) to be registered as an Event Gateway Service in API Connect.
- **Registering an analytics service**
  Configure at least one analytics service. The analytics service is always associated with a gateway service, from which it collects API event data.
- **Registering a portal service**
  Define one or more portal services in your API Connect on-premises cloud.
- **Associating an analytics service with a gateway service**
  To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.
- **Enabling OpenTelemetry configuration**
  Open Telemetry (OTel) is an open framework for creating and managing telemetry data, which might be traces, metrics or logs. OTel is not an alternative to monitoring tools, rather it enhances them. OTel typically supports the handling of traces, metrics, and logs.
- **Setting visibility for a service**
  The visibility setting determines which provider organizations can access a service.

- Configuring and managing your server environment

Creating an availability zone

An Availability Zone is a logical group of one or more API Connect services. The Default Availability Zone is created during installation.

About this task

Availability zones allow you to logically group API Connect services to suit your environment. For example, you can group gateway services according to the region or data center they are located in.

The Default Availability Zone is created during the installation process.

When you create an availability zone, you should provide a descriptive title; a name is generated automatically for internal identification. For example:

Table 1. Example availability zones

Title	Name
US Availability Zone	us-availability-zone
Hampshire Availability Zone	hampshire-availability-zone
Newport Availability Zone	newport-availability-zone
London South Availability Zone	london-south-availability-zone

One of the following roles is required to add and manage Availability Zones:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Procedure

Follow these steps to add one or more additional Availability Zones to your on-premises cloud:

1. In the Cloud Manager, click  Topology.
2. You will see the current Availability Zones configured in your cloud. The Default Availability Zone is created at installation. To add another Availability Zone, choose Create Availability Zone.
3. Enter the following values:

Field	Description
Title (required)	Enter a descriptive title for the availability zone. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.

4. Click Create to complete the operation.

Results

The availability zone will be added on the Topology page. You can now add gateway, analytics, and portal services to the availability zone.

- Registering an analytics service
- Registering a portal service

Registering a gateway service

A gateway service is required to handle incoming traffic for APIs.

Before you begin

Before registering a DataPower® gateway service in Cloud Manager, the API Connect Gateway subsystem must be installed as a subsystem in your Kubernetes cluster, or enabled on the DataPower appliance. For a Kubernetes environment, see DataPower Gateway subsystem on Kubernetes. For appliances, see *Configuring the API Connect Gateway Service* in the appropriate version of the DataPower documentation.

About this task

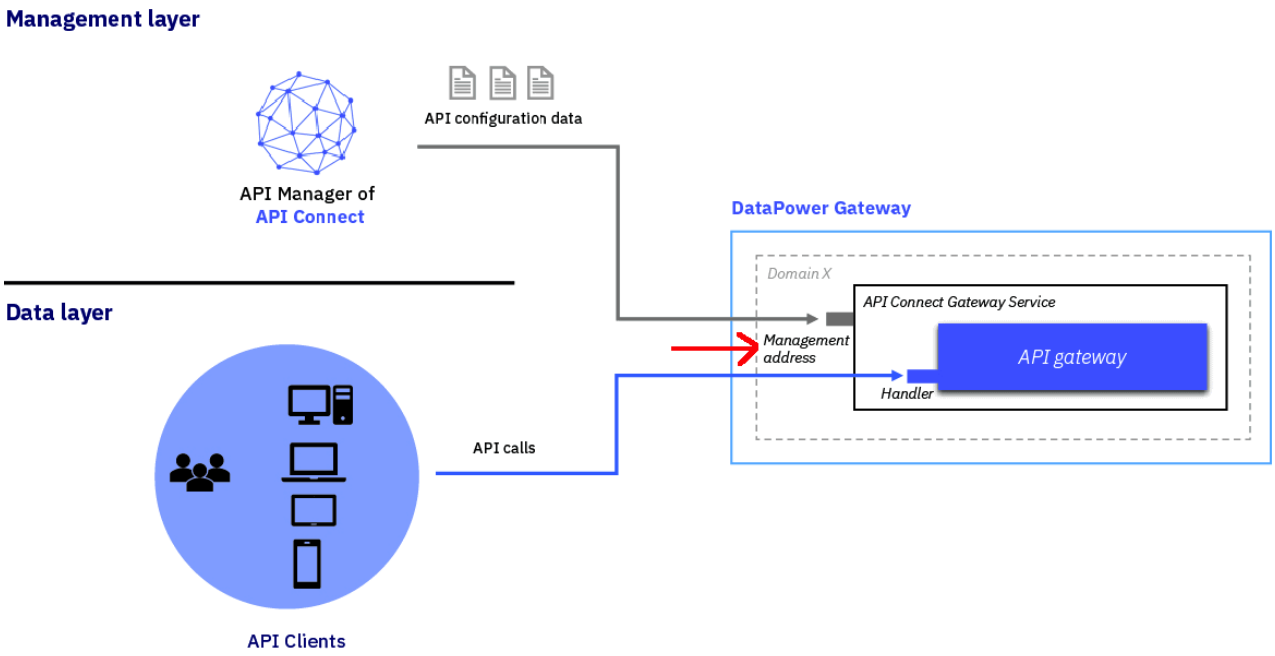
A gateway service represents a cluster of gateway servers that host published APIs and provide the API endpoints used by client applications. Gateways execute API proxy invocations to backend systems and enforce API policies including client identification, security and rate limiting.

One of the following roles is required to register and manage DataPower gateway services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Note: You can also register, and manage, DataPower gateway services using the developer toolkit CLI; for details, see the toolkit CLI reference documentation.

Procedure



Complete the following steps to configure a DataPower gateway service for your cloud:

1. In the Cloud Manager, click  Topology.
2. From the availability zone that will contain the DataPower gateway service, select Register Service.
3. On the Configure Service page, select DataPower Gateway as the service type. Select the gateway type that you want to create, either DataPower Gateway (v5 compatible) or DataPower API Gateway. For a description of the gateway types, see API Connect gateway types.
   Note: The option to enable LDAP connection pooling is only supported with the DataPower API Gateway v10.6.0.0 or later.
4. Enter the values to configure the DataPower gateway service. Obtain the endpoints from your deployment configuration. For a Kubernetes environment, the endpoints are configured by the following values in the CR (custom resource) file. For an appliance, the endpoint is configured in DataPower.

Field	Description
Title (required)	Enter a descriptive display title for the DataPower gateway service.
Name (required)	This field is populated for and is used as the internal field name.
Summary (optional)	Enter a brief description.
Management endpoint on the gateway service: Endpoint (required)	Enter the API Connect Gateway Service endpoint. • For a Kubernetes environment, the Management Endpoint is the endpoint created in the CR (custom resource). See DataPower Gateway subsystem on Kubernetes for more information. • For an appliance, the Management Endpoint is the *Management address* to the API Connect Gateway Service shown in the gateway service connection diagram. For one gateway, this takes the form *https://<ip-address-for-gateway>:3000*. For multiple gateways, it would be the address:port of the load balancer • If you are using **`in-cluster`** communication, set this to the service endpoint URL for the gateway, which has the format: **`https://<name>.<namespace>.svc`** where: ◦ *<name>* is the **`name`** property from the gateway subsystem CR. If you are using the top-level CR this is **`<apic instance name>-gw`** ◦ *<namespace>* is the namespace that the gateway CR exists in.
Management endpoint on the gateway service: TLS client profile (required)	Specify the TLS client profile to use when the management subsystem initiates communication with the gateway. The client profile contains the TLS client certificate that is presented to the gateway when establishing a secure connection. Important: • Do not leave this property unset. You must specify a client profile for secure management to gateway communication (mTLS). If you do not want to use mTLS, then you can configure JWT instead: ◦ Use JWT instead of mTLS on VMware. ◦ Use JWT instead of mTLS on Kubernetes and OpenShift. • The default profile to use is Gateway management client TLS client profile:1.0.0. On a Kubernetes or OpenShift deployment where the management and gateway subsystems are in the same namespace, the gateway service is automatically configured (during installation) to trust the Gateway management client TLS client profile:1.0.0. • If you want to use a different client certificate, do not update the Gateway management client TLS client profile:1.0.0, create a new client profile that uses the certificate you want. See Creating a TLS client profile. • If you are registering a gateway appliance, then configure your gateway to trust the client profile that you select. For more information about configuring TLS on your gateway appliance, see ◦ ../com.ibm.apic.install.doc/tapic_install_datapower_gateway_apigwy.html. ◦ ../com.ibm.apic.install.doc/tapic_install_datapower_gateway_v5compat.html. Do not configure your gateway appliances with client authentication disabled.
Management endpoint on the gateway service: Use in-cluster communucation	If you want to use **`in-cluster`** communication between the management and gateway subsystems, then enable this switch. For more information about this option, see In-cluster or external communication between subsystems. If you are not sure, then leave this switch disabled (the default).
Management endpoint on the gateway service: Use JWT for gateway authentication to analytics service	If you plan to associate an analytics service with this gateway, and you want to use JWT authentication between the gateway and analytics service, then enable this switch. If this switch is not enabled, then mutual TLS authentication is used between the gateway and analytics service. For more information about JWT security, see Enable JWT security instead of mTLS
Use LDAP connection pool	Enable this option when you want to optimize LDAP user registry processing by enabling LDAP connection pooling. Connection pooling reduces overhead and improves performance by maintaining a pool of connections and assigning them as needed. When a connection is closed, it is returned to the connection pool for future use. Note: LDAP connection pooling is supported only with the DataPower API Gateway v10.6.0.0 or later. You cannot enable LDAP connection pooling during the initial registration of the DataPower API Gateway service. Instead, complete the registration steps and click Save; then edit the registration to enable the use of connection pools. Configure the following settings for the connection pool: • Max pool size: (Defaults to 35 connections) The maximum number of connections for an LDAP **`server:port:BindDN`** combination in the LDAP connection pool. For example, if the LDAP connection pool has six combinations and this value is 10, each combination supports 10 connections and the connection pool can have 60 connections. • Idle timeout: (Defaults to 120 seconds) The length of time, in seconds, before an idle connection is removed from the connection pool. • Document cache size: (Defaults to 0 bytes) The maximum size of the LDAP cache, in bytes. The largest supported cache size is 2147483647 bytes. Using a cache improves performance by reducing the number of times that the LDAP server must be contacted.

Field	Description
Enable AI Gateway	For the new DataPower API Gateway service, AI Gateway is enabled by default in API Connect v10.0.8.1. If you are upgrading to v10.0.8.1 from the previous versions, this property is disabled for all existing DataPower API Gateway services. When AI Gateway service is enabled, it allows you to access AI Gateway policies directly on the DataPower API Gateway. For details, see Using the AI Gateway to support APIs for AI applications. When you disable AI Gateway, the following actions occur: • AI Gateway policies that were not used by any published APIs are deleted. • AI Gateway policies that were used by any published APIs remain intact.
API invocation endpoint: API endpoint base (required)	Enter the base portion of the URL that maps to the base portion of the URL for incoming API traffic. It is a public FQDN with additional paths that are specific to your API calls. For example: **https://api.mycompany.com** Note: If you are using the DataPower API Gateway, HTTP/2 is enabled automatically on the API invocation endpoint. If you are using the DataPower Gateway (v5 compatible), HTTP/2 is not supported on the API invocation endpoint.
API invocation endpoint: Server Name Indication (SNI) - Host name	For supporting Server Name Indication (SNI) at the API Endpoint Base. The default hostname of '*' is required to allow all hosts. Enter other host names as needed. Wild card format is supported. The SNI capability enables you to serve multiple TLS secure host names through the same Gateway service, using the same IP address and port, without requiring them to use the same TLS profile. Note: To allow requests from clients that don't support SNI, you **must** include a host name value of '*'.
API invocation endpoint: Server Name Indication (SNI) - TLS server profile	The TLS server profile that supports the given hostname for SNI. The server profile that is selected here contains the server certificate that is presented to callers of the APIs you publish on the gateway. By default this profile is set to Default TLS server profile. Best practice is to create your own TLS server profile that contains the certificate you want on your API invocation endpoint. For more information about configuring TLS server profiles, see TLS profiles overview. API Gateway only Restriction: If you are using the DataPower API Gateway, HTTP/2 is enabled automatically on the API invocation endpoint. Therefore, using a TLS server profile that supports only TLS protocol version 1.3 is not supported and will result in the gateway being unable to receive API traffic. You must use a TLS server profile that includes TLS protocol version 1.2 as one of its supported protocols. This restriction does not apply if you are using the DataPower Gateway (v5 compatible), which does not support HTTP/2.
OAuth shared secret (optional)	For sites using native OAuth providers, enter the shared secret that will be used by all API calls going through the gateway. Note: The specified shared secret must be 64 characters (64 bytes) in length, prefixed with `0x`, and must consist only of hexadecimal characters. For example: `0xa354282f227c10250511ae9c9e8c7ed9f4f1bd0d7c04cb6d5bd178f8c62296e3`

The following diagram illustrates the DataPower gateway service connection:

5. When you are finished, click Save.
6. If you want, you can delete the gateway service as follows;
   a. If the gateway service is already in use by any of the catalogs, you must disable the gateway service as follows:
      i. Log in to API Manager.
      ii. Click Manage, then select the catalog.
      iii. Click Catalog settings.
      iv. Click Gateway services.
      v. Click Edit.
      vi. Remove the checkmark from the corresponding gateway service.
      vii. Click Save.
   b. Log in to the Cloud Manager user interface.
   c. In the navigation list, click Topology.
   d. Click the options menu icon alongside the corresponding gateway service, then select Delete.
   e. Click Delete on the confirmation prompt.

Results

The DataPower gateway service is added to the appropriate availability zone for your cloud.

What to do next

Associate the DataPower gateway service with an analytics service, and set the visibility for the gateway. Add additional DataPower gateway services, or add one or more event gateway services, analytics services, or portal services.

- **Policies deployed on registration**
  This section provides details about the out-of-the-box (OOTB) policies that are automatically deployed to the DataPower API Gateway.

Related tasks

- Registering a portal service
- Registering an analytics service
- Associating an analytics service with a gateway service
- Setting visibility for a service

Policies deployed on registration

This section provides details about the out-of-the-box (OOTB) policies that are automatically deployed to the DataPower® API Gateway.

The following table shows the list of policies that are included in the registration process.

Built-in policy	OpenAPI policy	Description
Token Mediation	token-mediation	The Token Mediation policy acts as a mediator for OAuth tokens by caching the token and exchanging it for a session cookie via a set-cookie header. It enables clients to retrieve the cached token from policy or have the policy set the HTTP Authorization header for OAuth resource access.

Registering an event gateway service

Configure your IBM® Event Endpoint Management instance (Manager) to be registered as an Event Gateway Service in API Connect.

Before you begin

The Event Endpoint Management instance must be configured to trust API Connect before you register the Event Gateway Service. For instructions, see the *Retrieve the API Connect JSON Web Key Set (JWKS) endpoint*, *Configure Event Endpoint Management to trust API Connect*, and *Enabling mutual TLS* sections in the Configure an Event Endpoint Management Manager as an Event Gateway Service documentation.

About this task

Event Endpoint Management provides the capability to describe and catalog your Kafka topics as event sources, and to grant access to application developers within the organization. Application developers can discover event endpoints and configure their applications to access them through the event gateway. With Event Endpoint Management, developers can control access to the event endpoints, and also control what data can be produced to them or consumed from them.

For more information on Event Endpoint Management, see the Event Endpoint Management introduction in the IBM Event Automation documentation.

One of the following roles is required to register and manage services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Procedure

Create the TLS Client profile to use when contacting the Event Endpoint Management instance.

1. Create a client TLS keystore:
   a. Click  > Crypto Material > Keystore > Create.
   b. Upload the manager-client-key.pem file in Step 1.
   c. Upload the manager-client.pem file in Step 2.
   d. Click Save.
2. Create a client TLS truststore:
   a. Click Truststore > Create.
   b. Upload the cluster-ca.pem file.
   c. Click Save.
3. Create a TLS client profile:
   a. Click TLS client profile > Create.
   b. Select the new keystore and truststore.
   c. Select Allow insecure server connections.

d. Click Save.

Retrieve the Event Gateway endpoints.

4. Retrieve the Event Gateway management endpoint:
   To register an Event Endpoint Management instance with API Connect, you must provide the management endpoint on the event gateway, which defines where configuration updates from API Connect are sent. Retrieve the endpoint from Event Endpoint Management as follows:

   - OpenShift web console:
     - Log in to the OpenShift Container Platform web console using your login credentials.
     - Click Networking > Routes.
     - Click Project and select the project where the Event Endpoint Management instance is installed.
     - Use the search bar to find the route with the Name ending in `apic`.
     - Copy the URL for the management endpoint from the Location column.
   - CLI:
     - Log in to your Kubernetes cluster as a cluster administrator by setting your `kubectl` context.
     - Set the context to the namespace where your Event Endpoint Management instance is installed:

       ```
       kubectl config set-context --current --namespace=<namespace>
       ```

     - List the ingress resources and locate the API Connect ingress for your instance; unless overridden, the name ends in `-apic`:

       ```
       kubectl get ingress
       ```

     - Copy the URL for the ingress resource from the `Host` column.
5. Retrieve the Event Gateway client endpoint:
   To register an Event Endpoint Management instance with API Connect, you must provide an endpoint which defines where clients should connect to so they can consume events. Depending where you have deployed your Event Gateway, the steps to retrieve the client endpoint will differ:

   - OpenShift web console:
     - Log in to the OpenShift Container Platform web console using your login credentials.
     - Click Networking > Routes.
     - Click Project and select the project where the Event Endpoint Management instance is installed.
     - Use the search bar to find the route with the Name ending in `ibm-egw-rt`.
     - Copy the URL for the client endpoint from the Location column.
     - Edit the URL to remove the `https://` protocol prefix, and to append the port `:443` as a suffix.
   - CLI:
     - Log in to your Kubernetes cluster as a cluster administrator by setting your `kubectl` context.
     - Set the context to the namespace where your Event Endpoint Management instance is installed:

       ```
       kubectl config set-context --current --namespace=<namespace>
       ```

     - List the ingress resources and locate the API Connect ingress for your instance; unless overridden, the name ends in `-ibm-egw-rt`:

       ```
       kubectl get ingress
       ```

     - Copy the URL for the ingress resource from the `Host` column.
   - Stand-alone deployment:
     When deployed as a stand-alone gateway, the client endpoint value to use will be the name of the docker host running the gateway, and the `GATEWAY_PORT` value specified when starting the gateway container.

Register the Event Gateway Service in API Connect:

6. Log in to Cloud Manager as an administrator.
7. Click Topology.
8. On the Topology page, click Register Service.
9. On the Configure Service page, click the Event Gateway Service tile.
10. On the Configure Event Gateway Service page, configure the service by completing the following fields:

Field	Description
Title (required)	Enter a descriptive display title for the Event Gateway Service.
Name (required)	This field is populated for and is used as the internal field name.
Summary (optional)	Enter a brief description.
Service endpoint configuration: Management endpoint on the gateway service	Enter the Event Gateway management endpoint URL that you retrieved in step 4.
Service endpoint configuration: TLS client profile	Specify the TLS Client profile to use when contacting the event gateway through the management endpoint.
API invocation endpoint: API endpoint base	Enter the Event Gateway client endpoint URL that you retrieved in step 5.
API invocation endpoint: Server Name Indication (SNI) - Host	Supports SNI (Server Name Indication) at the API Endpoint Base URL. The default hostname of '*' is required to allow all hosts; add other host names as needed. Wild card format is supported. The SNI capability enables you to serve multiple TLS secure host names through the same event gateway service, using the same IP address and port, without requiring them to use the same TLS profile. Note: To allow requests from clients that don't support SNI, include a host name value of '*'.
API invocation endpoint: Server Name Indication (SNI) - TLS server profile	The TLS server profile that supports the specified hostname for SNI. The server profile that is selected here contains the server certificate that is presented to callers of the APIs you publish on the gateway. By default this profile is set to Default TLS server profile. Best practice is to create your own TLS server profile that contains the certificate you want on your API invocation endpoint. For more information about configuring TLS server profiles, see TLS profiles overview.

11. Click Save.

12. If you want, you can delete the event gateway service as follows;
    a. If the event gateway service is already in use by any of the catalogs, you must disable the event gateway service as follows:
        i. Log in to API Manager.
        ii. Click Manage, then select the catalog.
        iii. Click Catalog settings.
        iv. Click Gateway services.
        v. Click Edit.
        vi. Remove the checkmark from the corresponding event gateway service.
        vii. Click Save.
    b. Log in to the Cloud Manager user interface.
    c. In the navigation list, click Topology.
    d. Click the options menu icon alongside the corresponding event gateway service, then select Delete.
    e. Click Delete on the confirmation prompt.

Registering an analytics service

Configure at least one analytics service. The analytics service is always associated with a gateway service, from which it collects API event data.

Before you begin

You must complete the following tasks:

- Creating an availability zone
- Registering a gateway service

About this task

The analytics service collects API event data from the gateway service. In Cloud Manager, you configure the analytics service and then associate it with one or more gateways. Multiple gateways can be associated with a single analytics service, but each gateway can be associated with only one analytics service.
One of the following roles is required to register and manage analytics services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

When you register the analytics service, you must select from one of three inter-subsystem communication methods. Before you decide which method to use, familiarize yourself with the difference between **external** and **in-cluster** communication: In-cluster or external communication between subsystems. If you are an OVA user, or are in doubt as to what communication method to use, then use the default **external** setting.

The analytics subsystem has two separate communication flows:

- Management to analytics. The management service communicates with the analytics subsystem to query for analytics data to present in the UI dashboards. This flow is known as "analytics queries".
- Gateway to analytics. The gateway sends API event data to the analytics service. This flow is known as "analytics ingestion".

What you select depends on what is most suitable for your network configuration. The options are:

Use **external** communication for both ingestion and queries
: This option is the default, and is what is used for analytics services that are upgraded from a pre-10.0.5.3 release. For VMware deployments, or if your analytics subsystem is in a different environment then **external** is the only option that you can use. Both the gateway and the management service communicate with the analytics service by using the external endpoint, which is a Kubernetes **ingress** or OpenShift **route** depending on your platform.

Use **in-cluster** communication for both ingestion and queries
: You can select **in-cluster** if you have a Kubernetes or OpenShift deployment where all subsystems are within the same cluster. When this option is selected, the management, gateway, and analytics subsystems communicate with each other through internal service endpoints rather than externally accessible **ingresses** (Kubernetes) or **routes** (OpenShift).

Use **in-cluster** for ingestion and **external** for queries, or the other way around
: You can select this option if you have a Kubernetes or OpenShift deployment and you have some of your subsystems installed in the same cluster. When this option is selected, you can use different communication methods for the different analytics communication flows. For example, the management to analytics communication can use **in-cluster**, and the gateway to analytics can use **external**. You might choose this configuration if your gateway is in a different cluster to the rest of your subsystems.

Procedure

Complete the following steps to configure the analytics services for your cloud:

1. In the Cloud Manager, click Topology.
2. Select Register Services > Analytics in the Availability Zone where you have the gateways you want to associate with the analytics service.
3. Enter the values to configure the analytics service:

Field	Description
Title	Enter a descriptive title for the analytics service.
Name	This field is auto-populated by the system and used as the internal field name.
Summary	Enter a brief description.

Field	Description
Service endpoint configuration: Communication method.	Select your communication method, for more information on the options see, Communication types. If your API Connect deployment is OVA then you must select the first option: Use **external** communication for both ingestion and queries.

Service endpoint configuration: **External** analytics endpoint.	Enter the fully qualified domain name for the analytics ingestion endpoint that you defined during installation. To determine the endpoint, run the following command:
	• Kubernetes
	`kubectl get ingress -n <namespace>`
	The endpoint has **-ai-** in its name:
	`NAME CLASS HOSTS ADDRESS PORTS AGE`
	`def-analytics-ai-endpoint nginx a7s-in.example.com 80, 443 87d`
	• OpenShift
	`oc get routes -n <namespace>`
	The endpoint has **-ai-** in its name:
	`NAME CLASS HOSTS ADDRESS PORTS AGE`
	`def-analytics-ai-endpoint nginx a7s-in.example.com 80, 443 87d`
	• VMware
	`apicup subsys get <analytics subsystem>`
	The endpoint is the value of property **analytics-ingestion**.
	Note: Kubernetes and OpenShift: This field is disabled if "Use **in-cluster** communication for both ingestion and queries" is set as the communication type.

Service endpoint configuration: TLS client profile for **external** analytics endpoint.	Select the TLS Client Profile to use for management to analytics subsystem communication. The Client Profile applies to the endpoint that you specified in the previous row. The default is "Analytics Ingestion TLS client profile". This field is disabled if "Use **in-cluster** communication for both ingestion and queries" is set as the communication type.
Service endpoint configuration: **In-cluster** analytics endpoint.	Enter the fully qualified domain name for the analytics ingestion service endpoint. The format of the service endpoint is `https://<name>.<namespace>.svc` where: • *<name>* is the **name** property from the analytics subsystem CR. If you are using the top-level CR this is **<apic instance name>-a7s**. • *<namespace>* is the namespace that the analytics CR exists in. This field is disabled if Use **external** communication for both ingestion and queries is set as the communication type.
Service endpoint configuration: TLS client profile for **in-cluster** endpoint.	Select the TLS Client Profile to use for management to analytics subsystem communication. The Client Profile applies to the Endpoint that you specified in the previous row. The default is "Analytics Ingestion TLS client profile". This field is disabled if Use **external** communication for both ingestion and queries is set as the communication type.
Service endpoint configuration: Use **in-cluster** endpoint for analytics queries.	If you want the management subsystem to use the **in-cluster** service endpoint to communicate with the analytics subsystem, then select this option. If this option is not selected, then the management subsystem uses the **external** endpoint. Selection of **external** or **in-cluster** communication between the gateway and analytics subsystem is done when the gateway is associated with the analytics service, see Associating an analytics service with a gateway service. This setting is enabled when "Use **in-cluster** for ingestion and **external** for queries, or the other way around" is selected.

4. Click Save to complete the operation.
5. If you want, you can delete the analytics service as follows;
   a. If a gateway service is associated with the analytics service, you must unassociate the gateway service as follows:
      i. Log in to the Cloud Manager user interface.
      ii. In the navigation list, click Topology.
      iii. Click the options menu icon alongside the corresponding gateway service, then select Unassociate.
   b. Locate the analytics service to delete.
   c. Click the options menu icon alongside the analytics service, then select Delete.
   d. Click Delete on the confirmation prompt.

Results

The analytics service is added to your cloud settings.

What to do next

- Associate the analytics service with one or more gateway services: Associating an analytics service with a gateway service.
- Set preferred retention and rollover settings for the new analytics service: Retention and rollover.

Related tasks

- Registering a gateway service
- Registering a portal service

Registering a portal service

Define one or more portal services in your API Connect on-premises cloud.

Before you begin

You must complete the following tasks:

- Creating an availability zone
- Registering a gateway service
- Configuring an email server for notifications
- Setting up notifications

Note:
When you create or register a Developer Portal service, the portal subsystem checks that the portal web endpoint is accessible. However sometimes, for example due to the complexity of public and private networks, the endpoint cannot be reached. The following example shows the errors that you might see in the `portal-www` pod, admin container logs, if the endpoint cannot be reached:

```
An error occurred contacting the provided portal web endpoint: example.com
The provided Portal web endpoint example.com returned HTTP status code 504
```

In this instance, you can disable the portal web endpoint check so that the Developer Portal service can be created successfully.
To disable the endpoint check, complete one of the following updates depending on your platform:

On Kubernetes and OpenShift (with no apiconnectcluster)

Add the following section to the Portal custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

On IBM® Cloud Pak for Integration (deployed through apiconnectcluster)

Add the following section to the Apiconnectcluster custom resource (CR) template:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: ptl-www
```

On VMware

In your `apicup` project, create a file called ptl-extra-values.yaml (or edit the file if one already exists), and add the following section:

```
spec:
  template:
  - containers:
    - env:
      - name: PORTAL_SKIP_WEB_ENDPOINT_VALIDATION
        value: "true"
      name: admin
    name: www
```

Run the following commands:

```
apicup subsys set <ptl_subsys> extra-values-file <path-to-ptl-extra-values-yaml-file>

apicup subsys install <ptl_subsys>
```

About this task

Each Availability Zone contains one or more portal services. The portal service provides a Developer Portal used by application developers to discover APIs and onboard consumers. An email server must be configured and set as the email server for the cloud before registering a portal service.
One of the following roles is required to register and manage portal services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Important: It's not recommended to have more than 100 sites per Developer Portal service. Note that it's not necessary to have a portal site for every Catalog, for example Catalogs that are only for API Developers don't need a portal site, as the APIs can be tested by using credentials from the API Manager. If more than 100 sites are required, you should configure additional Developer Portal services.

Procedure

Complete the following steps to configure the portal services for your cloud:

1. In the Cloud Manager, click Topology.
2. In the Availability Zone that will contain the portal service, select Register Services > Portal.
3. Enter the values to configure the portal service.

Field	Description
Title (required)	Enter a descriptive title for the portal service. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Summary (optional)	Enter a brief description.
Management endpoint on the portal service: Endpoint (required)	Enter the IP address, fully-qualified host name, service, or ingress name. Used for communication with API Manager. • In a Kubernetes deployment, the endpoint is defined in the CR by **`api.portal.$STACK_HOST`** . See Developer Portal subsystem on Kubernetes. • If configured during installation in a VMware environment, it is the `apicup subsys set portal portal-admin` value. • If you are using **`in-cluster`** communication, set this to the service endpoint URL for the portal, which has the format: **`https://<name>.<namespace>.svc`** where: ◦ *<name>* is the **`name`** property from the portal subsystem CR. If you are using the top-level CR this is **`<apic instance name>-ptl`** ◦ *<namespace>* is the namespace that the portal CR exists in.
Management endpoint on the portal service: TLS client profile (optional)	Select the TLS Client Profile that will be used to communicate with the portal service. The profile applies to the Management Endpoint.
Management endpoint on the portal service: Use **`in-cluster`** communication switch	If you want to use **`in-cluster`** communication between the management and portal subsystems, then enable this switch. For more information about this option, see In-cluster or external communication between subsystems. If you are not sure, then leave this switch disabled (the default).
Portal website URL (required)	The URL that will be used for public access to the portal. • In a Kubernetes deployment, the endpoint is defined in the CR by **`portal.$STACK_HOST`** . See Developer Portal subsystem on Kubernetes. • If configured during installation in a VMware environment, it is the `apicup subsys set portal portal-www <portal>.<hostname>.<domainname>` value. Multiple portal-www endpoints may be configured, as described here in these topics: Defining multiple portal endpoints for a Kubernetes environment and Defining multiple portal endpoints for a VMware environment.

4. When you are finished, click Save.
5. If you want, you can delete the portal service as follows;
   a. If the portal service is already in use by any of the catalogs, you must delete the portal site as follows:
      i. Log in to API Manager.
      ii. Click Manage, then select the catalog.
      iii. Click Catalog settings.
      iv. Click Portal.
      v. Click the options menu icon alongside Portal section, next to the Edit option, then select Delete.
      vi. Click Delete on the confirmation prompt.
   b. Log in to the Cloud Manager user interface.
   c. In the navigation list, click Topology.
   d. Click the options menu icon alongside the portal service, then select Delete.
   e. Click Delete on the confirmation prompt.

Results

The portal service is configured in your cloud and can be used to publish APIs.

Associating an analytics service with a gateway service

To collect data about your API usage and other statistics, you must associate an analytics service with each gateway service. You can associate multiple gateway services with one analytics service, but each gateway can be associated with only one analytics service.

About this task

The associated analytics service receives API event data from the gateway service.

To associate an analytics service with a gateway, you must first configure at least one analytics service and one gateway service.

One of the following roles is required to associate an analytics service with a gateway service:

- Administrator
- Topology Administrator
- Owner
- A custom role with the **`Topology:Manage`** permission

Follow these steps to associate an analytics service with a gateway service:

Procedure

1. In the Cloud Manager, click  Topology.
2. In the section for the Availability Zone you want to work on, locate the gateway service that requires an analytics service in the SERVICE column.
3. Locate the ASSOCIATED ANALYTICS SERVICE column.
4. If an analytics service is configured, the Associate Analytics service link is enabled for each gateway service. Click Associate Analytics Service in the same row as the gateway service that requires an analytics service.
5. In Associate Analytics Service, you see the name of the gateway service and a list of analytics services that have been configured in your cloud.
6. Select the analytics service to associate with the gateway service by adding a checkmark next to the analytics services.
7. If you specified **`in-cluster`** communication when you registered the analytics service, you can enable the gateway to send API event data to the internal analytics endpoint. Enable the "Use internal endpoint for ingestion of analytics data from the gateway service" switch. For more information about **`in-cluster`** communication, see Communication types.
8. Click Associate.
9. To remove the associated analytics service, select Unassociate analytics service from the actions menu. The gateway stops sending API event data to the analytics service.

Results

The analytics service is associated with a gateway service and starts to receive API event data from that gateway.

Enabling OpenTelemetry configuration

Open Telemetry (OTel) is an open framework for creating and managing telemetry data, which might be traces, metrics or logs. OTel is not an alternative to monitoring tools, rather it enhances them. OTel typically supports the handling of traces, metrics, and logs.

Note: OTel support is available for DataPower 10.6.0.1 and above.

Create OpenTelemetry configuration

Create the Open Telemetry configuration as follows and save it as otel.cfg. If needed, update the parameters as per the requirement. The default ports for OpenTelemetry are 4317 (grpc) or 4318 (http).
Note: Change the hostname and PORT in the following config to match your OTel Agent.

```
%if% available "otel-exporter"
otel-exporter "otel-exp"
  type http
  hostname otel-collector.cp4i.svc.cluster.local
  traces-path "/v1/traces"
  logs-path "/v1/logs"
  port 4318
  http-content-type binary
  timeout 10
  processor batch
  max-queue-size 2048
  max-export-size 512
  export-delay-interval 5000
exit
%endif%
%if% available "otel-sampler"
otel-sampler "otel-samp"
  parent-based
  type always-on
exit
%endif%
%if% available "otel"
otel "api-otel"
  exporter otel-exp
  sampler otel-samp
exit
%endif%
```

```
apigw "apiconnect"
  otel api-otel
exit
```

Create the gateway extension

1. In the same directory as `otel.cfg`, run the following command to create a `.zip` file for the `otel.cfg` file.

   ```
   zip otelgwextension.zip otel.cfg
   ```

2. Create a file that is named `manifest.json` with content specified as follow referring the newly created `.zip` file's name.

   ```
   {
       "extension": {
           "files": [
               {
                   "filename": "otelgwextension.zip",
                   "deploy": "immediate",
                   "type": "extension"
               }
           ]
       }
   }
   ```

3. Create a final `.zip` file that contains both the updated `manifest.json` file and the `.zip` file created in previous step.

   ```
   date=$(date +%s)
   zip otel-ext-$date.zip manifest.json otelgwextension-$date.zip
   ```

Load the Gateway Extension

1. Log in to the Cloud Manager as administrator.
2. In the navigation list, click Topology.
3. From the list of gateway services, click ⋮ next to the gateway service and select Configure gateway extension.
4. Click Add.
5. Either drag and drop the .zip file of the gateway extension or click to upload the same.
6. Click Save.
7. Wait a few minutes for the extension to apply.

Setting visibility for a service

The visibility setting determines which provider organizations can access a service.

Before you begin

You must complete the following tasks:

- Create additional availability zones if needed, see Creating an availability zone
- Register at least one gateway service, see Registering a gateway service
- Register other services.

About this task

The visibility setting controls which provider organizations can use a service. The default visibility setting is Public.

One of the following roles is required to set the visibility for services:

- Administrator
- Topology Administrator
- Owner
- A custom role with the `Topology:Manage` permission

Procedure

Follow these steps to set the visibility for the services in your on-premises cloud:

1. In the Cloud Manager, click Topology.
2. From the list of gateway services, click ⋮ next to the gateway service and select Edit visibility.
3. Select the visibility setting for the service. The options are:
   - Private - the service is not visible and cannot be used by any provider organization
   - Public - the service is visible and can be used by all provider organizations
   - Custom - the service is visible only to the provider organizations designated by you
4. For Custom visibility, select the provider organizations that will be able to use the service.
5. Click Save.

Results

For Private, the service cannot be used by any provider organizations. For Public, the service can be used by all provider organizations. For Custom, the service can be used by the provider organizations that you designate.

Managing authentication and security

Secure Cloud Manager and API Manager as well as your Catalogs with a user registry. Secure your APIs with OAuth. Create TLS profiles to ensure that information you share among web servers will not be stolen or tampered with.

As Cloud Administrator or Topology Administrator (or with a custom role that contains the `Settings:Manage` permission), you can configure the following authentication and security mechanisms:

- User registries to authenticate users of Cloud Manager and API Manager and of your Catalogs and APIs.
- OAuth providers to provide protection for APIs.
- TLS profiles to secure transmission of data through the Gateway to external web sites and among web servers.

The following topics describe how to configure user registries, OAuth providers, and TLS profiles:

- **User registries overview**
  API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.
- **TLS profiles overview**
  Create TLS profiles to manage the TLS communication between subsystems, external systems, and your API invocation endpoint.
- **OAuth Provider overview**
  API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

Related concepts

- User registries overview

User registries overview

API Connect supports several types of user registries for authenticating users. The credentials for all users of Cloud Manager, API Manager, and the Developer Portal must be stored in a user registry.

Introduction to user registries

A user registry holds unique user account credentials, primarily usernames and passwords, which are accessed during authentication for logging into Cloud Manager, API Manager, the Developer Portal, and also for calling APIs (if the API is configured to use Basic Authentication in the Security Definition). The Cloud Administrator configures user registries to ensure that all users are successful at logging in.

User registries also provide security when calling APIs. For information on configuring Security Definitions for APIs, see Creating a basic authentication security definition.

User registries are configured as Resources. Once the user registry has been configured as a resource in Resources > User registries, the next step is indicate the active user registries for your cloud in Settings > User registries. The user registry must be made active in your cloud in order to make it available for authentication. When a user logs into Cloud Manager or API Manager, the specified user registry is queried for credentials to confirm the user's identity. To make a user registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings > Onboarding; for more information see Creating and configuring Catalogs.

Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access. In Cloud Manager and API Manager, a registry cannot be changed after a user is invited to be the owner of a provider organization, even if the invitation is not yet accepted.

User registries in API Connect serve the following primary functions:

- To authenticate a user at login time based upon username and password.
- To store basic profile information such as first name, last name, and email address.
- To provide secure access to Catalogs.
- To provide Basic Authentication for APIs when called by an application.

In order to log in to Cloud Manager, API Manager, the Developer Portal, or access a catalog, a user must have valid credentials (username and password) stored in a user registry that is configured in API Connect.

The Security Definition for an API can be configured to require a username and password, called the Basic Authentication method. With Basic Authentication, the username and password are included in the HTTP authorization header, and the credentials are verified through user registry.

User registries that are configured in Cloud Manager have the following characteristics:

- They are available to Cloud Manager, API Manager, the Developer Portal, and for Basic Authentication for APIs.
- They are available to provider organizations, as determined by the visibility setting.
- They can be edited and deleted only in Cloud Manager.

User registries that are configured in API Manager have the following characteristics:

- They are available to the Developer Portal (for Catalogs) and for Basic Authentication for APIs.
- They are available only to the Provider Organization that created them.

User registries supported by API Connect

API Connect integrates with several types of user registries to accommodate all security solutions. You can use your corporate LDAP registry, an Authentication URL, or an LUR to provide secure access to Cloud Manager, API Manager, the Developer Portal, and APIs. API Connect includes two internal databases that serve as local user registries, or LURs. The Providers LUR supports credentials for Provider organizations and the Admin LUR supports credentials for the Administrator organization. Multiple registries may be configured.

The following user registry types can serve as a resource in API Connect:

- Local user registry (LUR) - An internal database of usernames and passwords stored on the local server. Contains the Admin user account which may not be modified or deleted.
- LDAP - A user registry definition that points to an existing corporate LDAP directory. May be set up as case-sensitive.
- Authentication URL - Accesses a URL that points to a service for validating user credentials.
- OpenID Connect (OIDC).

- **Configuring an Authentication URL user registry**
  An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.
- **Configuring a shared custom user registry**
  You can configure a custom user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal.
- **Configuring an LDAP user registry in the Cloud Manager**
  You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.
- **Configuring a Local User Registry**
  A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.
- **Configuring an OIDC user registry in Cloud Manager**
  Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.
- **Setting visibility for a user registry**
  The visibility setting determines which provider organizations can access a resource, for example, user registries.
- **Deleting a user registry**
  As the Cloud Manager administrator, you can delete user registries.
- **Removing a user from a user registry**
  As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

- Setting visibility for a user registry

Configuring an Authentication URL user registry

An Authentication URL user registry provides a simple mechanism for authenticating users by referencing a custom identity provider.

About this task

This topic describes how to configure a new Authentication URL user registry as a Resource in your cloud. After the user registry is configured, you must select it for use in your cloud in Settings > User Registries. See Selecting user registries for Cloud Manager and API Manager.

One of the following roles is required to configure user registries.:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:
API Connect issues an HTTP **`GET`** call to the Authentication URL endpoint, sending the user's credential. The following example shows a call made to an Authentication URL identity provider with an endpoint defined as **`https://myauthurl.example.com/user/authenticate`**:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
```

If the Authentication URL endpoint returns an HTTP status code of **`200`**, the user authenticates successfully. An HTTP status code other than **`200`** indicates a failed login attempt. API Connect forwards any HTTP Header starting with **`X-`** (with the exception of **`X-Client-Certificate`**), and Cookie to the Authentication URL identity provider, to aid the authentication decision; for example:

```
GET /user/authenticate HTTP/1.1
 Host: myauthurl.example.com
 Authorization: Basic c3Bvb246Zm9yaw=
 X-Forwarded-For: 8.8.9.9
 X-Custom-Header-From-Customer: special
 Cookie: MyCookie=VGhpc0lzV2lja2VkQW1hemluZw==
```

When a user is presented with the form for completing their API Connect user registration, which fields are pre-populated depends on which fields are returned in the response from the Authentication URL identity provider. If any of the following fields are returned, they will be pre-populated in the registration form:

- `username`
- `email`
- `first_name`
- `last_name`

If the `username` field is not returned, the registration form displays the user name that was provided by the user. The pre-population capability requires that the response from the Authentication URL identity provider satisfies the following conditions:

- The `Content-Type` must be `application/json`.
- The response body format must be JSON.

A sample response is as follows:

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: no-store
Pragma: no-cache

{
  "username":"myuser",
  "email":"myuser@example.com",
  "first_name":"My",
  "last_name":"User"
}
```

Procedure

1. In the Cloud Manager, click  .
2. Select User Registries to see the list of current user registries in your cloud.
3. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. Select Authentication URL User Registry and enter the following parameters:

Field	Description
Title (required)	Enter a descriptive name to use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Summary (optional)	Enter a brief description.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the `Title` of the User Registries when rendering them at the login page, rather than the `Display Name`.
URL (required)	Enter the URL for the authentication service. When establishing authentication, API Connect makes a GET call to the URL. The call includes the user name and password it has collected from the user in its authorization header. Either `200 OK` or `401 Unauthorized` will be returned.
TLS Client Profile (optional)	Select a TLS Client Profile to allow secure authentication with a specific web server.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend Authentication URL server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

5. Click Save.

Results

The Authentication URL user registry is saved and is available to be selected as a user registry for Cloud Manager or API Manager by selecting it in Settings > User Registries. It can also be used for Basic Authentication in the Security Definition for an API.

- Configuring an LDAP user registry in the Cloud Manager
- Setting visibility for a user registry

Configuring a shared custom user registry

You can configure a custom user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal.

Before you begin

To configure a custom user registry as a resource in the Cloud Manager, the external user directory must be created and available to use with your API Connect ecosystem.

Custom user registries can be used for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal, but cannot be used to secure APIs.

One of the following roles is required to configure a custom user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create a custom user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific custom user registry can be used for authenticating Developer Portal users, while a shared custom user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared custom user registry. If you want to create an organization-specific registry, see Creating an organization-specific custom user registry for more information. Note also that the visibility of a user registry is set to **`shared`** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see Setting visibility for a user registry.
Note:

- You can also create custom user registries by using the API Connect REST APIs (see the API Connect REST API documentation).

You can use the following instructions to create a writable or a read-only custom user registry.

API Connect provides two methods for creating a shared custom user registry in the Cloud Manager, as described in the following sections:

- Creating a shared custom user registry by using the Cloud Manager UI
- Creating a shared custom user registry by using the developer toolkit CLI

Creating a shared custom user registry by using the Cloud Manager UI

You configure a custom user registry by first creating a custom user registry type that defines your external user registry, and then creating a new custom user registry resource that references the custom user registry type that you just created. To make the registry available for user authentication, you need to add the registry to the Cloud Manager, or to the API Manager, or both, depending on your requirements. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the custom user registry type.

Creating a custom user registry type

Use the following instructions to create a custom user registry type that defines your external user registry.

1. In the Cloud Manager, click  Resources.
2. Click Create in the User registry type section.
3. Enter the following information:

Property	Description
Title	A descriptive name of the custom user registry type to display in the UI. For example, *My custom user registry type*.
Name	The name of the user registry type. This name is auto-generated, and is used in CLI commands.
Version	The version number of the custom user registry type.
Summary	A brief description of the custom user registry type.
Properties	Enter the properties of your external user registry. Must include the property: **`remote: true`** This property must be set to **`true`** to indicate that this is an external user registry.
Secured Endpoint	Denotes the external registry secured endpoint section of the custom user registry type.
URL	The secure endpoint of your external user registry interface, where your platform REST API is located. It is made up of the URL and port, for example: ***`https://custom.ms.com:8888`*** API Connect will make REST calls to this endpoint for the user registry actions.
TLS Client Profile	Optionally set the TLS Client Profile URL that the custom server requires.

Property	Description
Headers	Optionally complete the user-defined header section to your external registry specification.
Configuration schema	Optionally complete the user-defined configuration schema section to your external registry specification.

4. Click Create. A new user registry with a Type of Custom is displayed in the User registry type list.

Creating a custom user registry resource

Use the following instructions to create a new custom user registry resource that references the custom user registry type that you just created.

1. Click Create in the User Registries section of Resources.
2. Click the Custom user registry tile.
3. Enter the following information:

Property	Description
Custom type	The name of the custom user registry type that you just created. For example, *my-custom-user-registry-type*. Use the drop-down arrow to select different custom user registry types.
Title	A descriptive name to display in the UI.
Name	The name of the custom user registry. This name is auto-generated, and is used in CLI commands.
Summary	A brief description of the custom user registry.
Endpoint	Optional endpoint information.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend server: • **Only** select Case sensitive if your backend server supports case-sensitivity. • Do **not** select Case sensitive if your backend server does not support case-sensitivity. Note: • The Developer Portal does not support case sensitive usernames. • After at least one user has been onboarded into the registry, you cannot change this setting.
User registry managed	Determines whether API Connect manages your user registry. Valid values are: • `true` - select the checkbox • `false` - clear the checkbox
User managed	Determines whether your user registry is writable or not. Select the checkbox to set to `true` for writable. Clear the checkbox for the non-writable option.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Create. The new user registry is displayed in the User registries list.

Adding your custom user registry to the Cloud Manager or API Manager login

To make the custom user registry available for user authentication in the Cloud Manager or the API Manager, you must set it as active in the Settings > User Registries section of the Cloud Manager UI. See Selecting user registries for Cloud Manager and API Manager for more information.
If you want to make the custom user registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Catalog settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see Creating and configuring Catalogs.

Creating a shared custom user registry by using the developer toolkit CLI

You configure a custom user registry by first configuring an integration document that defines your external user registry, and then creating a new custom user registry resource that references the integration document that you just created. You use developer toolkit CLI commands to create the integration document, and then the custom user registry. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. When the custom user registry is used for authentication, API Connect makes a REST call to the endpoint of your external registry, as defined in the integration document.

Logging in to the management server CLI

Before you can define the custom user registry, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your integration document

You define the configuration of your external user registry in an ***integration_file*.yaml** document, as shown in the following example.

```
integration: '1.0.0'
integration_type: 'user_registry'
info:
  name: 'custom_user_registry'
  version: '1.0.0'
  title: 'Custom External User Registry'
  summary: 'Configure External User Registry'
properties:
  remote: true
secured_endpoint:
  endpoint:  'https://custom.ms.com:8888'
  tls_client_profile_url: {$tslClientProfileUrl}
headers:
  key1: value1
  key2: value2
configuration_schema:
  option_config1:
     type: string
  option_config2:
     type: boolean
```

The integration document properties are described in the following table:

Property	Description
integration_type	The type of integration, which in this case is **user_registry**.
info	Denotes the information section for the integration document.
name	The name of the user registry type, for example ***custom_user_registry***. This name is used in the user registry file to denote the registry type.
version	The version number of the integration document.
title	A descriptive name to display in a graphical user interface.
summary	A brief description of the integration document.
properties	Denotes the property section of the integration document.
remote	Indicates that this is an external user registry. Must be set to **true**.
secured_endpoint	Denotes the external registry endpoint section of the integration document.
endpoint	The secure endpoint of your external user registry interface, where your platform REST API is located. It is made up of the url and port, for example: ***https://custom.ms.com:8888*** API Connect will make REST calls to this endpoint for the user registry actions.
tls_client_profile_url	Optionally set the TLS Client Profile URL that the custom server requires.
headers	Complete the user-defined header section to your external registry specification.
configuration_schema	Complete the user-defined configuration schema section to your external registry specification.

Save your ***integration_file*.yaml** so it can be accessed by the **integrations:create** command in the following section.

Creating your custom integration

To create your custom user registry integration, run the following CLI command:

```
apic integrations:create --server mgmt_endpoint_url --subcollection user-registry integration_file.yaml
```

where:

- ***mgmt_endpoint_url*** is the management platform API endpoint URL.
- ***integration_file*** is the name of the YAML file that defines the configuration of your external user registry.

At this point API Connect makes a REST request call to the **endpoint** that is configured in the integration document, and the external platform REST API will need to return the requested information.
On completion of the integration creation, the command displays the following summary details:

```
integration_name custom_integration_url
```

The ***integration_name*** is derived from the **name** property in the configuration YAML file. The ***custom_integration_url*** is the URL with which the integration can be accessed. Both properties are needed when defining your custom user registry in the next section.
After your custom integration has completed successfully, you can continue to create the custom user registry.

Defining your custom user registry

You define the configuration of your custom user registry in a ***custom_config_file*.yaml** file, as shown in the following example.

```
name: 'custom_registry_name'
title: 'display_title'
```

```
registry_type: 'custom_user_registry'
integration_url: custom_integration_url
case_sensitive: true_or_false
user_managed: true_or_false
user_registry_managed: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: 'provider_title'
configuration:
  custom_config1: 'value1'
  customize: true
```

The registry properties are described in the following table:

Property	Description
`name`	The name of the custom user registry. This name is used in the CLI commands.
`title`	A descriptive name to display in a graphical user interface.
`registry_type`	The registry type that you configured in the `name` property in the integration document, for example `custom_user_registry`.
`integration_url`	The custom integration URL in your API Connect configuration. You can determine the custom integration URL by using the following CLI command: `apic integrations:list --server mgmt_endpoint_url --subcollection user-registry` Or you can copy and paste from the summary of the integration creation.
`case_sensitive`	Determines whether your user registry is case-sensitive. Valid values are: • `true` • `false` To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set `case_sensitive` to `true` if your backend LDAP server supports case-sensitivity. • Set `case_sensitive` to `false` if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
`user_managed`	Determines whether your user registry is writable or not. Must be set to `true` for writable. Set to `false` if you don't want the registry to be writable.
`user_registry_managed`	Determines whether API Connect manages your user registry. Valid values are: • `true` • `false`
`email_required`	Determines whether an email address is required as part of the user onboarding process. Valid values are: • `true` • `false` If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
`email_unique_if_exist`	Determines whether email addresses must be unique within the user registry. Valid values are: • `true` • `false` Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
`identity_providers`	An array containing the details of your custom server, where: • `name` - is the name of the custom server and is the name that is used in CLI commands • `title` - is the display name of the custom server
`configuration`	The user-defined configuration based on the `configuration_schema` that is defined in the integration document.

Save your `custom_config_file.yaml` so it can be accessed by the `user-registries:create` command in the following section.

Creating your custom user registry

To create your shared custom user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin custom_config_file.yaml
```

where:

- `mgmt_endpoint_url` is the platform API endpoint URL.
- `--org admin` means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- `custom_config_file` is the name of the YAML file that defines the configuration of your custom user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The `registry_name` is derived from the `name` property in the custom user registry YAML file. The `registry_url` is the URL with which the custom registry resource can be accessed.

Your shared custom user registry is now created; see the following sections for instructions on how to make the registry available to users.

Configuring your custom registry for Cloud Manager or API Manager login

If you want to make your custom registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Determine what the current user registries are, because you will need to confirm these as well as add your new custom registry:

   ```
   apic user-registry-settings:get --server mgmt_endpoint_url --output -
   ```

   This command outputs a list of all the current user registries in your environment, similar to the following example:

   ```
   type: user_registry_setting
   api_version: 2.0.0
   name: user-registry-setting
   admin_user_registry_default_url: >-
     https://server.com/api/user-registries/xxxxx/xxxxx-1234
   admin_user_registry_urls:
     - >-
       https://server.com/api/user-registries/xxxxx/xxxxx-1234
   provider_user_registry_default_url: >-
     https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   provider_user_registry_urls:
     - >-
       https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   created_at: '2019-09-30T12:22:19.467Z'
   updated_at: '2019-10-17T10:05:37.867Z'
   url: 'https://server.com/api/cloud/settings/user-registries'
   ```

3. Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registry-settings:update --server mgmt_endpoint_url -
   ```

   The following message is output:

   ```
   Reading USER_REGISTRY_SETTING_FILE arg from stdin
   ```

4. If you want to make your custom registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

   ```
   admin_user_registry_urls:
     - >-
       current_admin_user_registry_urls
     - new_custom_user_registry_url
   ```

   where:
   - *current_admin_user_registry_urls* are the current admin user registry URLs, as listed in Step 2 in the **admin_user_registry_urls** section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_custom_user_registry_url* is the URL of your new custom user registry, as determined in Step 1.

5. If you want to make your custom registry available for authenticating API Manager users, enter the following data, followed by a new line:

   ```
   provider_user_registry_urls:
     - >-
       current_provider_user_registry_urls
     - new_custom_user_registry_url
   ```

   where:
   - *current_provider_user_registry_urls* are the current provider organization user registry URLs, as listed in Step 2 in the **provider_user_registry_urls** section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_custom_user_registry_url* is the URL of your new custom user registry, as determined in Step 1.

6. Press **CTRL D** to terminate the input. A confirmation message is output, for example:

   ```
   user-registry-setting   https://server.com/api/cloud/settings/user-registries
   ```

   where *server.com* is your management server endpoint.

Configuring your custom registry in a Catalog

If you want to make your custom registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your custom user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Log in to the management server as a member of a provider organization by entering the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   For full details of the **apic login** command, see Logging in to a management server.

3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns:

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   `user_registry_url: custom_registry_url`

   where `custom_registry_url` is the URL of your custom registry, obtained in step 1.
5. Press `CTRL D` to terminate the input.

Configuring an LDAP user registry in the Cloud Manager

You can use the Cloud Manager UI to configure an LDAP user registry as a shared resource to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a shared resource in the Cloud Manager, the LDAP directory must be created for use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, to authenticate users to the Cloud Manager and the API Manager, or for securing a Catalog to authenticate Developer Portal users.
Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for authenticating Developer Portal users in a specific provider organization. While a shared LDAP user registry can be used across the Cloud Manager, the API Manager, and the Developer Portal components in your environment.

This topic describes how to configure a shared LDAP user registry that is available to all of the provider organizations in your API Connect environment. If you want to create an organization-specific registry, see Creating an LDAP user registry in API Manager for more information. Note also that the visibility of a user registry is set to **`shared`** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see Setting visibility for a user registry.
Note:

- If you configure your LDAP user registry to be writable (by selecting the User Managed check box on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create and manage LDAP user registries by using the developer toolkit CLI (see Using the CLI to configure a shared LDAP user registry), and by using the API Connect REST APIs (see the API Connect REST API documentation).
- You can map external LDAP groups to API Connect user roles to enable greater control of user access, but this configuration can be done only by using the developer toolkit CLI; see Using the CLI to configure a shared LDAP user registry for details.

You create an LDAP user registry by configuring a set of properties in the Cloud Manager UI. If you want to enable writable LDAP, you must complete the Attribute Mapping section by selecting the User Managed checkbox, and providing the mapping of your source LDAP attribute names to the target API Connect values. You can also change a registry to be read-only again by clearing the User Managed checkbox. After configuring the user registry, you must set it as active in Settings > User Registries. To make the registry available to the Developer Portal, you must define the registry for consumer onboarding in the associated Catalog. To secure APIs with an LDAP registry, you must configure security definitions.

For general information about authenticating with LDAP, see LDAP authentication.

Procedure

Follow these steps to configure a new LDAP user registry as a shared resource in the Cloud Manager UI.

1. In the Cloud Manager, click  Resources.
2. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
3. Select LDAP User Registry for the user registry type, and enter the following information:

Field	Description
Title	Enter a descriptive name to display on the screen.
Name	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.

Field	Description
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Address	Enter the IP address or host name of the LDAP server.
Port	Enter the Port number that API Connect can use to communicate with the LDAP registry. For example, `389`.
Select a TLS Client Profile (optional)	Select the TLS Client Profile that the LDAP server requires.
Select an LDAP protocol version	Select the version number for the LDAP protocol that you are using.
Remote directory is Microsoft Active Directory	Select this option if you use Active Directory.
Case sensitive	To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** select Case sensitive if your backend LDAP server supports case-sensitivity. • Do **not** select Case sensitive if your backend LDAP server does not support case-sensitivity. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Enable External Group Mapping	Enable this property if you want user to use this user registry to map external LDAP groups to API Connect user roles to enable more control of user authorization.
Email required	Select this check box if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this check box if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Next and enter the authentication information, which will vary depending on the selected Authentication Method. The choices are:
   - Compose DN - Select this format if you want users to login with a username that is also part of their LDAP Distinguished Name (DN). For example, using `uid` for user login where the user's LDAP DN is: `uid=<username>,ou=People,dc=company,dc=com`. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator.
   - Compose UPN - Select this format if your LDAP directory supports binding with User Principal name such as **`john@acme.com`**. This is applicable if you are using Microsoft Active Directory as your LDAP directory. If you are unsure whether your LDAP directory supports binding with LPNs, contact your LDAP administrator.
     Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
   - Search DN - Select this format if you want users to login with a username that is not part of their LDAP DN. For example, if the user's LDAP DN was: `uid=<username>,ou=People,dc=company,dc=com` and you want them to login with the email. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator. Optionally select a scope to specify which part of the directory information tree is examined:
     Optionally select a scope to specify which part of the directory information tree is examined:
     - Whole subtree (default)
     - Base object
     - Single level

   For all of the authentication methods:

   If you are creating an LDAP registry to authenticate users of an API, you can specify an LDAP authorization group to restrict API access. To be able to call an API that is secured by the LDAP registry, a user must successfully authenticate with their LDAP user ID and password **and** they must be a member of the specified authorization group. The authorization group can be a Static Group or Dynamic Group. A static group is one in which the individual members of the group are explicitly listed. A dynamic group is one which is defined according to the set of attributes that the group members share in common.

5. For authentication method Compose DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the DN of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Part of the DN that comes before the username for binding or authentication. For example, `bind_prefix: 'uid='`.
Suffix	Part of the DN that follows the username, specifying the user's location in the LDAP tree. For example, `bind_suffix: ',ou=users,dc=apic,dc=com'`.
Base DN (optional)	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN. The base DN where the LDAP server starts its search for user entries. For example, `search_dn_base:'dc=apic,dc=com'`.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

6. For authentication method Compose UPN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the DN of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.

Field	Description
Suffix	Part of the DN that follows the username for constructing the UPN. For example, `@domain.com`.
Use group authentication (optional)	Enter the Filter condition for the group.

7. For authentication method Search DN, enter the following:

Field	Description
Bind Method	Anonymous or Authenticated. If specific permissions are not needed to search the registry, select Anonymous Bind. Or, if specific permissions are necessary, select Authenticated Bind.
Admin DN	For Authenticated Bind, enter the DN of a user authorized to perform searches in the LDAP directory. For example `cn=admin,dc=company,dc=com`.
Admin Password	For Authenticated Bind, enter the user password for the Admin DN.
Prefix	Part of the search filter that comes before the username. The last attribute must be the one you chose to use for login. For example, `'(&(uid='`.
Suffix	Part of the search filter that follows the username. For example,`'))(objectClass=organizationalPerson)'`. Notice how it always begins with a `'))'` which is meant to close the attribute filter for the last attribute specified in `search_dn_filter_prefix`.
Base DN	Enter a base DN in the Base DN field, or click Get Base DN to populate the field with a retrieved base DN. The base DN where the LDAP server starts its search for user entries. For example, `search_dn_base:'dc=apic,dc=com'`.
Use group authentication (optional)	Static or Dynamic. For Static Group, enter the Group Based DN, Prefix, and Suffix. For Dynamic Group, enter the Filter condition for the group.

8. Optional: Click Test configuration to test the settings for your LDAP user registry. Enter valid credentials to ensure that you can access the LDAP database.
9. Optional: If you want to make your LDAP user registry writable, select the User Managed checkbox in the Attribute Mapping section, and provide the mapping of your source LDAP attribute names to the target API Connect values. Click Add to add each name/value pair, specified as follows:
   - LDAP ATTRIBUTE NAME - is the name of the source LDAP attribute.
   - API CONNECT VALUE - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.

   The default user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`, as shown in the following example:

LDAP ATTRIBUTE NAME	API Connect VALUE
`dn`	`uid=[username],ou=users,dc=company,dc=com`
`cn`	`[first_name] [last_name]`
`sn`	`[last_name]`
`mail`	`[email]`
`userPassword`	`[password]`

   You must ensure that you enter the correct attribute mapping values for your LDAP configuration, to enable API Connect to access the LDAP database. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
10. Click Create.
    Your new LDAP registry is shown in the list of User Registries on the Resources page.

What to do next

If you use DataPower® API Gateway, you can optionally update the service and enable LDAP connection pooling to improve performance. For instructions, see the options in step 4 of Registering a gateway service.

To make the LDAP registry available for user authentication in the Cloud Manager and the API Manager, you must set it as active in the Settings > User Registries section. See Selecting user registries for Cloud Manager and API Manager for more information.

If you want to make the LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. In the API Manager UI, click Manage followed by the relevant Catalog, and then click Settings > Onboarding. In the Catalog User Registries section, click Edit, select the user registry, and click Save. For more information, see Creating and configuring Catalogs.

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

- **Using the CLI to configure a shared LDAP user registry**
  You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Using the CLI to configure a shared LDAP user registry

You can use the developer toolkit CLI to configure an LDAP user registry to provide user authentication for the Cloud Manager, the API Manager, and the Developer Portal. APIs can also be secured with an LDAP user registry.

Before you begin

To configure an LDAP user registry as a resource in the Cloud Manager, the LDAP directory must be created and available to use with your API Connect ecosystem.

LDAP registries can be used to secure APIs, or for authenticating users to the Cloud Manager, the API Manager, and the Developer Portal.

Important: If you are using an LDAP registry to secure APIs, the STARTTLS protocol, which upgrades an insecure protocol to a secure one by applying TLS security, is not supported.
One of the following roles is required to configure an LDAP user registry:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

You can create an LDAP user registry that is specific to a provider organization, or one that can be shared and available to all of the provider organizations in your API Connect environment. An organization-specific LDAP user registry can be used for onboarding and authenticating Developer Portal users, while a shared LDAP user registry can be used for authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to configure a shared LDAP user registry. If you want to create an organization-specific registry, see Using the CLI to create an organization-specific LDAP user registry for more information. Note also that the visibility of a user registry is set to **`shared`** by default. However, you can change the visibility setting to make the registry private, or visible only to specific provider organizations. For more information, see Setting visibility for a user registry.
Note:

- If the LDAP user registry is configured as writable (by enabling the **`user-managed`** property on the registry), you can use the Developer Portal UI for onboarding and authenticating new Developer Portal users, as well as those users that already exist in the LDAP database. A writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
- You can also create LDAP user registries by using the Cloud Manager UI (see Configuring an LDAP user registry in the Cloud Manager), and by using the API Connect REST APIs (see the API Connect REST API documentation).
- If you are using the DataPower® API Gateway, LDAP group authentication is not supported.
- You can map external LDAP groups to API Connect user roles to enable more control of user authorization by using the developer toolkit CLI. The following instructions explain how to set the **`external_group_mapping_enabled`** configuration on your LDAP user registry resource. For information about how to set external role mapping on your API Connect user roles, see Configuring LDAP group mappings on Cloud Manager user roles.

You configure an LDAP user registry by first defining the registry details in a configuration file. You then use a developer toolkit CLI command to create the registry, passing the configuration file as a parameter. Finally, to make the registry available for user authentication, you need to configure the registry in the management server, or in the appropriate Catalog, or both, depending on your requirements. To secure APIs with an LDAP registry, you must configure security definitions. You can use the following instructions to create a writable or a read-only LDAP user registry.

For general information about authenticating with LDAP, see LDAP authentication.

Logging in to the management server CLI

Before you can define the LDAP user registry configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **`default-idp-1`**.
For full details of the login command, see Logging in to a management server.

For more information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Defining your LDAP configuration

You define the configuration of your LDAP user registry in an ***ldap_config_file*.yaml** file, as shown in the following example. Note that the actual contents of your YAML file will vary depending on the authentication method of your LDAP server, and this is explained in the following tables.

```
name: registry_name
title: "display_title"
integration_url: LDAP_integration_url
user_managed: true_or_false
user_registry_managed: false
directory_type: ad
external_group_mapping_enabled: true_or_false
case_sensitive: true_or_false
email_required: true_or_false
email_unique_if_exist: true_or_false
identity_providers:
 - name: provider_name
   title: provider_title
endpoint:
  endpoint: "ldap_server_url_and_port"
configuration:
  authentication_method: authentication_method
  authenticated_bind: "true_or_false"
  admin_dn: "admin_dn"
  admin_password: admin_password
  search_dn_base: "search_dn_base"
  search_dn_scope: search_dn_scope
  search_dn_filter_prefix: prefix
  search_dn_filter_suffix: suffix
  attribute_mapping:
    dn: "distinguished_name"
    cn: "common_name"
    sn: "last_name"
    mail: "email_address"
    userPassword: "password"
```

The registry properties that are common to each authentication method are described in the following table:

Property	Description
name	The name of the registry. This name is used in CLI commands.
title	A descriptive name to display in a graphical user interface.
integration_url	The LDAP integration URL in your API Connect configuration. You can determine the LDAP integration URL by using the following CLI command: **apic integrations:list --server *mgmt_endpoint_url* --subcollection user-registry**
user_managed	Determines whether your user registry is writable or not. Must be set to **true** for writable LDAP. You can change this setting to **false** if you don't want the registry to be writable; see the Switching your LDAP registry between writable and read-only section at the end of this topic for details. Note that a writable LDAP user registry cannot be used to authenticate Cloud Manager and API Manager users.
user_registry_managed	Must be set to **false** for LDAP. Determines whether API Connect manages your user registry. Only LUR registries are managed by API Connect.
directory	Specify one of the of following values for the directory type: • **ad** - Indicates that the LDAP is Microsoft Active Directory • **standard** - (Default value) Indicates any other LDAP
external_group_mapping_enabled	Determines whether your user registry supports LDAP group mapping. Valid values are: • **true** • **false** The default value is **false**.
case_sensitive	Determines whether your user registry is case-sensitive. Valid values are: • **true** • **false** To ensure proper handling of user name capitalization, you **must** ensure that your case-sensitivity setting here matches the setting on your backend LDAP server: • **Only** set **case_sensitive** to **true** if your backend LDAP server supports case-sensitivity. • Set **case_sensitive** to **false** if your backend LDAP server does not support case-sensitivity. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
email_required	Determines whether an email address is required as part of the user onboarding process. Valid values are: • **true** • **false** If set to **true**, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
email_unique_if_exist	Determines whether email addresses must be unique within the user registry. Valid values are: • **true** • **false** Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

Property	Description
`identity_providers`	An array containing the details of your LDAP server, where: • `name` - is the name of the LDAP server and is the name that is used in CLI commands • `title` - is the display name of the LDAP server
`endpoint`	The endpoint of your LDAP server, made up of the url and port, for example: `"ldap://server.com:389"`
`tls_profile`	Optionally set the TLS Client Profile that the LDAP server requires.
`protocol_version`	Optionally set the version number for the LDAP protocol that you are using. Valid values are: • `2` • `3` Defaults to `3` if not explicitly set.

The properties in the configuration section will vary depending on the selected authentication method. The three authentication methods are:

- `compose_dn` - Set this format if you can compose the user LDAP Distinguished Name (DN) from the user name. For example, `uid=<username>,ou=People,dc=company,dc=com` is a DN format that can be composed from the user name. If you are unsure whether Compose (DN) is the correct option, contact your LDAP administrator. If you are using an LDAP registry to secure APIs, `compose_dn` is not supported with the DataPower API Gateway.
- `compose_upn` - Set this format if your LDAP directory supports binding with User Principal Names such as `john@acme.com`. The Microsoft Active Directory is an example of an LDAP directory that supports Compose UPN authentication. If you are unsure whether your LDAP directory supports binding with UPNs, contact your LDAP administrator.
  Note: The Admin Bind DN and Admin Bind Password are not used with this authentication method.
- `search_dn` - Select this format if you cannot compose the user LDAP Distinguished Name from the user name; for example, if the base DNs of the users are different. This format might require an administrator DN and password to search for users in the LDAP directory. If your LDAP directory permits anonymous binds, you can omit the admin DN and password. If you are unsure if your LDAP directory permits anonymous binds, contact your LDAP administrator.

For authentication method `compose_dn`, set the following configuration properties:

Properties	Description
`authentication_method`	`compose_dn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`search_dn_base`	Optionally set a base DN, for example: `"dc=company,dc=com"`
`bind_prefix`	Set the prefix to the DN, for example: `(uid=`
`bind_suffix`	Set the suffix to the DN, for example: `)`

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:
	`ldap_registry_attribute_name``: "`*`apic_ldap_attribute_value`*`"`
	Where:
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

For authentication method `compose_upn`, set the following configuration properties:

Properties	Description
`authentication_method`	`compose_upn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.

Properties	Description
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`bind_suffix`	Enter the domain part of the user principal name. For example: `@acme.com`

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:
	
	`ldap_registry_attribute_name``: "`*`apic_ldap_attribute_value`*`"`
	
	Where:
	
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

For authentication method `search_dn`, set the following configuration properties:

Property	Description
`authentication_method`	`search_dn`
`authenticated_bind`	The bind method. Valid values are: • `"true"` - authenticated bind • `"false"` - anonymous bind If specific permissions are not needed to search the registry, select `"false"`. If specific permissions are necessary, select `"true"`.
`admin_dn`	If `authenticated_bind` is set to `"true"`, enter the Distinguished Name (DN) of a user authorized to perform searches in the LDAP directory. For example: `"cn=admin,dc=company,dc=com"`
`admin_password`	If `authenticated_bind` is set to `"true"`, enter the user password for the `admin_dn`.
`search_dn_base`	Optionally set a base DN, for example: `"dc=company,dc=com"`
`search_dn_scope`	Optionally set the search DN scope. The scope determines which part of the directory information tree is examined. Possible values are: • `base` • `one` • `sub` (default value)
`search_dn_filter_prefix`	Set the prefix to the DN, for example: `(uid=`
`search_dn_filter_suffix`	Set the suffix to the DN, for example: `)`

`attribute_mapping`	If `user_managed` is set to `true`, provide the mapping of your source LDAP attribute names to the target API Connect values. This mapping is configured as a name/value pair, specified as follows:
	
	`ldap_registry_attribute_name``: "`*`apic_ldap_attribute_value`*`"`
	
	Where:
	
	• *ldap_registry_attribute_name* - is the name of the source LDAP attribute
	• *apic_ldap_attribute_value* - is a string that represents the value that API Connect will populate the LDAP attribute with, by replacing the content contained in `[ ]` with the value that the user supplies when signing up.
	
	The user profile properties that API Connect requires during user registration are `username`, `first_name`, `last_name`, `email`, and `password`. The following extract shows an example of an attribute mapping:
	
	`attribute_mapping:`
	`  dn: "uid=[username],ou=users,dc=company,dc=com"`
	`  cn: "[first_name] [last_name]"`
	`  sn: "[last_name]"`
	`  mail: "[email]"`
	`  userPassword: "[password]"`

Save your *`ldap_config_file`*`.yaml` so it can be accessed by the `user-registries:create` command in the following section. See the Example section for an example configuration file.

Creating your LDAP user registry

To create your shared LDAP user registry, run the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin ldap_config_file.yaml
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- **--org admin** means that the registry will be created in the admin organization, which is required for a user registry to be shared.
- *ldap_config_file* is the name of the YAML file that defines the configuration of your LDAP user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

The *registry_name* is derived from the **name** property in the configuration YAML file. The *registry_url* is the URL with which the registry resource can be accessed. Your shared LDAP user registry is now created; see the following sections for instructions on how to make the registry available to users.

Configuring your LDAP registry for Cloud Manager or API Manager login

If you want to make your LDAP registry available for authenticating Cloud Manager and API Manager users, you must configure it on the management server.

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Determine what the current user registries are, because you will need to confirm these as well as add your new LDAP registry:

   ```
   apic user-registry-settings:get --server mgmt_endpoint_url --output -
   ```

   This command outputs a list of all the current user registries in your environment, similar to the following example:

   ```
   type: user_registry_setting
   api_version: 2.0.0
   name: user-registry-setting
   admin_user_registry_default_url: >-
     https://server.com/api/user-registries/xxxxx/xxxxx-1234
   admin_user_registry_urls:
     - >-
       https://server.com/api/user-registries/xxxxx/xxxxx-1234
   provider_user_registry_default_url: >-
     https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   provider_user_registry_urls:
     - >-
       https://https://server.com/api/user-registries/xxxxx/xxxxx-5678
   created_at: '2019-09-30T12:22:19.467Z'
   updated_at: '2019-10-17T10:05:37.867Z'
   url: 'https://server.com/api/cloud/settings/user-registries'
   ```

3. Enter the following command to update your user registries (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registry-settings:update --server mgmt_endpoint_url -
   ```

   The following message is output:

   ```
   Reading USER_REGISTRY_SETTING_FILE arg from stdin
   ```

4. If you want to make your LDAP registry available for authenticating Cloud Manager users, enter the following data, followed by a new line:

   ```
   admin_user_registry_urls:
     - >-
       current_admin_user_registry_urls
     - new_ldap_user_registry_url
   ```

   where:
   - *current_admin_user_registry_urls* are the current admin user registry URLs, as listed in Step 2 in the **admin_user_registry_urls** section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_ldap_user_registry_url* is the URL of your new LDAP user registry, as determined in Step 1.

5. If you want to make your LDAP registry available for authenticating API Manager users, enter the following data, followed by a new line:

   ```
   provider_user_registry_urls:
     - >-
       current_provider_user_registry_urls
     - new_ldap_user_registry_url
   ```

   where:
   - *current_provider_user_registry_urls* are the current provider organization user registry URLs, as listed in Step 2 in the **provider_user_registry_urls** section. Note that you must include all of the user registry URLs that you want to remain, listing each URL on a new line.
   - *new_ldap_user_registry_url* is the URL of your new LDAP user registry, as determined in Step 1.

6. Press **CTRL D** to terminate the input. A confirmation message is output, for example:

   ```
   user-registry-setting   https://server.com/api/cloud/settings/user-registries
   ```

   where *server.com* is your management server endpoint.

Configuring your LDAP registry in a Catalog

If you want to make your LDAP registry available for authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your LDAP user registry by using the following command (or you can copy and paste from the summary of the registry creation):

```
apic user-registries:list --server mgmt_endpoint_url --org admin
```

2. Log in to the management server as a member of a provider organization by entering the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   For full details of the **apic login** command, see Logging in to a management server.
3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns:

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: ldap_registry_url
   ```

   where *ldap_registry_url* is the URL of your LDAP registry, obtained in step 1.
5. Press **CTRL D** to terminate the input.

Switching your LDAP registry between writable and read-only

After an LDAP user registry has been created, it can be switched between writable and read-only by updating the **user_managed** property in the registry configuration. Complete the following steps.

1. Determine the name or ID of the LDAP user registry that you want to update, by running the following command (or you can use the summary from the registry creation):

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

   The command returns a list of all the user registries on that server, shown by name followed by their registry URL. The registry ID is located at the end of the URL, for example **https://company.com/api/user-registries/x-x-x-x-x/*registry_id***.
2. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic user-registries:update --server mgmt_endpoint_url --org admin registry_name_or_id -
   ```

   where ***registry_name_or_id*** is the name or ID of the LDAP user registry that you want to update (as determined in the previous step). The command returns:

   ```
   Reading USER_REGISTRY_FILE arg from stdin
   ```

3. Enter the following data, followed by a new line:

   ```
   user_managed: true_or_false
   ```

   where **true** makes the registry writable, and **false** makes the registry read-only.
4. Press **CTRL D** to terminate the input.

Note that if you are changing your registry from read-only to writable, you must also set the **attribute_mapping** configuration, as described in the previous registry property tables.

Using an LDAP user registry to secure APIs

If you want to use the LDAP user registry to secure APIs, see the following information:

- To use for basic authentication in the security definition for an API, see Creating a basic authentication security definition.
- To use for authentication in the User Security configuration for a native OAuth provider, see Configuring user security for a native OAuth provider.

For details of all the **apic user-registries** and **apic configured-catalog-user-registries** commands, see the toolkit CLI reference documentation.

Example

The following example shows a configuration file that uses the Search DN authentication method for setting up writable LDAP:

```
name: sdn-ldap
title: "SDN LDAP User Registry"
integration_url: https://mycompany.com/api/cloud/integrations/user-registry/xxx-xxx-xxx
user_managed: true
user_registry_managed: false
directory_type: standard
case_sensitive: false
identity_providers:
  - name: ldap
    title: "SDN LDAP Identity Provider"
endpoint:
  endpoint: "ldap://mycompany.com:389"
configuration:
  authentication_method: search_dn
  authenticated_bind: "true"
  admin_dn: "cn=admin,dc=company,dc=com"
  admin_password: xxxx
  search_dn_base: "dc=company,dc=com"
  search_dn_scope: sub
  search_dn_filter_prefix: (uid=
  search_dn_filter_suffix: )
  attribute_mapping:
    dn: "uid=[username],ou=users,dc=company,dc=com"
```

```
    cn: "[first_name] [last_name]"
    sn: "[last_name]"
    mail: "[email]"
    userPassword: "[password]"
```

Configuring a Local User Registry

A Local User Registry (LUR) can be configured to provide user authentication for both Cloud Manager and API Manager.

About this task

Local User Registries (LURs) are the default user registries included in API Connect. LURs are local databases included with API Connect. Two default LURs are installed and configured during installation of API Connect. They cannot be deleted. The default Admin user account is stored in the Provider LUR.

You can create and configure a new LUR. After you create it, you must set it as active in Settings > User Registries. See Selecting user registries for Cloud Manager and API Manager.

One of the following roles is required to configure user registries:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

Procedure

Follow these steps to configure a new LUR:

1. In the Cloud Manager, click  .
2. Click Create in the User Registries section.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
3. Select Local User Registry as the type for the user registry and enter the following information:

Field	Description
Title (required)	Enter a descriptive name for use on the screen.
Name (required)	The name that is used in CLI commands. The name is auto-generated. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Display Name (required)	The name that is displayed for selection by the user when logging in to a user interface, or activating their API Manager account. For details of user interface log in, and account activation, see Accessing the Cloud Manager user interface, Accessing the API Manager user interface, and Activating your API Manager user account. Note: The Developer Portal uses the **`Title`** of the User Registries when rendering them at the login page, rather than the **`Display Name`**.
Summary (optional)	Enter a brief description.
Case sensitive	Select this setting if user names are case-sensitive. Note: The Developer Portal does not support case sensitive usernames. Note: After at least one user has been onboarded into the registry, you cannot change this setting.
Email required	Select this checkbox if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this checkbox if email addresses must be unique within the user registry. For new Local User Registries, this setting is always selected; so if email addresses are contained in the user record, they must be unique. However, for existing Local User Registries this setting can be edited. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

4. Click Save.

Results

The user registry is saved and is available to be configured for user authentication in Cloud Manager or API Manager by selecting it in Settings > User Registries. See Selecting user registries for Cloud Manager and API Manager.

Configuring an OIDC user registry in Cloud Manager

Configure a shared OIDC user registry for user onboarding and authentication when multi-factor authentication (MFA) is required.

You can create an OIDC user registry that is specific to a provider organization, or that is shared and available to all the provider organizations in your API Connect environment. An organization-specific OIDC user registry is used for onboarding and authenticating Developer Portal users, while a shared OIDC user registry can be used for onboarding and authenticating Cloud Manager, API Manager, and Developer Portal users.

This topic describes how to create a shared registry. For information on how to create an organization-specific registry, see Creating an OIDC user registry in API Manager.

Important: If you are using X (formerly known as Twitter) as your OIDC provider, API Connect supports only the OAuth 1.0a method, so your X application must be configured to use OAuth 1.0a. Other OIDC providers support OAuth 2.0.
API Connect provides two methods for creating an OIDC user registry in Cloud Manager, as described in the following sections:

- Using the UI to configure an OIDC user registry
- Using the CLI to configure an OIDC user registry

Using the UI to configure an OIDC user registry

Use the Cloud Manager application's user interface to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

1. In the Cloud Manager navigation pane, click Resources.
2. Click User Registries.
3. Click Create and select OIDC User Registry.
   Important: Do not share user registries between the API Manager and the Developer Portal, or between Developer Portal sites when self-service onboarding is enabled or account deletions in any of the sites are expected. You should create separate user registries for them, even if the separate registries point to the same backend authentication provider (for example, an LDAP server). This separation enables the Developer Portal to maintain unique email addresses across the catalog, without API Manager needing the same requirement. It also avoids problems with users deleting their accounts from the Developer Portal that then affects their API Manager access.
4. On the Create OIDC User Registry page, use the fields in each of the following sections to configure the registry settings, and then click Create.
   Many of the registry settings are preconfigured to simplify the configuration steps.

   Provider Type
   : Use the settings in Table 1 to define the provider type.

Table 1. Provider Type settings

Field	Description
Provider Type	OIDC provider. Select one of the following supported OIDC providers: • Facebook • GitHub • Google • LinkedIn • Slack • X (formerly known as Twitter) • Windows Live • Standard OIDC (default value allows you to specify another provider)
Title	Provide a descriptive name for display purposes.
Name	Automatically generated. This name is used in CLI commands to reference the registry. For details of the CLI commands for managing user registries, see the toolkit CLI reference documentation.
Summary	Provide a brief description of the new registry.
Email required	Select this option if an email address is required as part of the user onboarding process. If selected, the source identity provider must supply the email address as part of the authentication process during onboarding. Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
Unique email address	Select this option if email addresses must be unique within the user registry. Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.

   Provider Endpoint
   : Automatically generated for most supported providers. In the Authorization Endpoint field, type the URL of the provider's authorization endpoint.

   Token Endpoint
   : Fill in the settings as described in Table 2.

Table 2. Token Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's token endpoint.
TLS	Select the TLS Client Profile for the token endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

   UserInfo Endpoint
   : Fill in the settings as described in Table 3.

Table 3. UserInfo Endpoint settings

Field	Description
URL	Preconfigured for most of the supported OIDC providers. Type the URL of the provider's userinfo endpoint. For LinkedIn, the endpoint changed and now uses the following value: `https://api.linkedin.com/v2/me` If you previously configure the OIDC registry using the legacy LinkedIn OIDC protocol, you do not need to specify this endpoint.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Email Endpoint

Required for the legacy LinkedIn OIDC protocol.

Due to changes in LinkedIn, the configuration settings for the OIDC registry in API Connect also changed. If you are configuring a new OIDC registry for LinkedIn, you can leave the Email Endpoint field blank.

If you previously configured an OIDC registry for use with the legacy LinkedIn OIDC protocol, update your configuration by providing the Email endpoint settings as described in Table 4. The new setting is required for the legacy LinkedIn OIDC protocol.

Table 4. Email Endpoint settings

Field	Description
URL	For the legacy LinkedIn OIDC protocol, this field defaults to the following value: `https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))` You can override the setting by typing in a new value.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

JWKS Endpoint

Fill in the settings as described in Table 5.

Table 5. JWKS Endpoint settings

Field	Description
URL	Type the URL of the read-only endpoint that contains the public keys' information in JWKS format.
TLS	Select the TLS Client Profile for the userinfo endpoint (OIDC must be configured to use TLS). Default is Default TLS Client Profile.

Logout

You can configure either of the following types of logout support, but not both:

- Logout redirect:
  Allows you to specify what the user sees after logging out of API Connect; for example, you might want to "redirect" the user to the OIDC provider's logout endpoint, or to another address. When the user logs out of API Connect, the browser is redirected to the specified URL for further processing by the specified URL.

- RP-initiated logout:
  Provides a more secure form according to the OpenID Connect RP-Initiated Logout 1.0 Profile. When the user logs out of API Connect, API Connect issues a POST request to the specified endpoint URL to clear the user's session. With this option, you can optionally provide an RP logout redirect endpoint URL as well.

Fill in the settings as described in Table 6.

Table 6. Logout options

Field	Description
Logout redirect URL	Optional. Provide a URL to redirect the browser when the user logs out of API Connect. If you use this option, do not enable the OIDC RP logout.
Enable OIDC RP logout	Select this option to use the RP-initiated logout instead of the conventional logout redirect. If you use this option, do not provide a Logout redirect URL. With the RP-initiated logout, you can optionally specify an RP-logout redirect URL.
URL endpoint that the RP will issue a POST request	Provide the URL to the endpoint where the POST request will be executed; for example, the authorization endpoint of the OpenID provider.
TLS	Select the TLS profile to use when sending the POST request to the OpenID provider endpoint.
RP logout redirect endpoint URL	Optional. Provide a URL where the OIDC provider can redirect after the logout operation. The URL functions as the `post_logout_redirect_uri`, as described in the OpenID Connect RP-Initiated Logout 1.0 Profile.
Include refresh_token in logout	Optional. Allow the refresh_token to be included, in addition to the id_token_hint, per the OpenID Connect RP-Initiated Logout 1.0 Profile.

Client Information

Fill in the settings as described in Table 7.

Table 7. Client Information settings

Field	Description
Client ID	Provide the client ID of the application that is registered with the selected OIDC provider.
Client Secret	Provide the client secret of the application that is registered with the selected OIDC provider. This field is optional when you create an OIDC directory of type Standard and set the Client Authentication Method to Data encoded form body. If you are not using the Client Secret, ensure that mutual TLS is configured with the OIDC provider. To enable mutual TLS, create a TLS profile and include it in the OIDC user registry setup.
Response Type	Preconfigured for most of the supported OIDC providers. Specify the data type of the response that will be received from the OIDC provider.
Scopes	Preconfigured for most of the supported OIDC providers. Specify the access scope for the OIDC provider.
Client Authentication Method	Preconfigured for most of the supported OIDC providers. Select the authentication method to be used with the OIDC provider. Options are: • HTTP Basic authentication schema • Data encoded form body

Additional Support

Optional. Select the additional security parameters described in Table 8.

Table 8. Additional security options

Security parameter	Setting name for CLI	Description
NONCE	`nonce`	Enable the NONCE extension to prevent compromised requests from being used again (replayed).
Proof Key for Code Exchange (PKCE)	`pkce`	Enable the PKCE extension to allow public clients to mitigate the threat of having the authorization code intercepted.

Advanced Features

Optional. Select the advanced features described in Table 9.

Table 9. Advanced features

Feature / UI Label	Setting name for CLI	Description
Auto onboard	`auto_onboard`	Allow users to executes calls to APIs without logging in first, provided they present a valid token issued by the OIDC provider. Note: Does not apply to consumer organizations.
Always use the userinfo endpoint	`userinfo`	Configures the OIDC user registry to always fetch user data from the userinfo endpoint, if populated.
Use Portal as Endpoint for external OIDC provider traffic	`proxy_redirect`	When authenticating users, redirect the external OIDC provider to communicate with the Developer Portal instead of API Manager. When enabled, the redirect URI for the Developer Portal should be set to `/ibm_apim/oidcredirect`. For details, see the Redirect URI.
Return third-party access token	`proxy_access_token`	Include the third-party OIDC access token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error. You can avoid the size issue by additionally enabling Return third-party access_token and id_token as separate claims so that the third-party tokens are not added to the access_token that is issued API Connect.
Return third-party id_token	`proxy_id_token`	Include the third-party OIDC id_token in the response. Note: Enable this setting for debugging purposes only. This setting is not recommended for use in a production environment. When this setting is enabled, the token size will increase when a request is made to API Connect using the token. The larger token size might exceed the HTTP protocol limit, resulting in an ERR_HTTP2_PROTOCOL_ERROR or ERR_CONNECTION_CLOSED error. You can avoid the size issue by additionally enabling Return third-party access_token and id_token as separate claims so that the third-party tokens are not added to the access_token that is issued API Connect.
Return third-party access_token and id_token as separate claims	`proxied_token_as_separate_claim`	Include the third-party OIDC tokens (the `proxy_access_token` and `proxy_id_token`) in the response as separate claims instead of adding them to the access_token issued by API Connect. To use this feature, you must enable at least one of the Return third-party access token and Return third-party id_token options. Separating the third-party tokens prevents them from affecting the size of the access_token issued by API Connect.
Token Relay	`token_relay`	Allow `access_token/refresh_token` to send in 302 redirect for logout
Userinfo POST	`post_userinfo`	If supported by your OIDC provider, by using HTTP POST method when contacting userinfo endpoint. Note: Not all OIDC providers support POST. Ensure that your OIDC provider supports this before you enable the feature.
Use IBM APIC token expiration setting from cloud	`override_provider_ttl`	Override the OIDC provider's token expiration setting with the access token and refresh token expiration settings that are configured in API Connect. For information on configuring the access token and refresh token expiration settings in API Connect, see Configuring timeouts for access tokens and refresh tokens.
Disable hash verification (CLI only)	`disable_hash_verification`	Disable `at_hash`, `c_hash`

User Mapping

Fill in the settings as described in Table 10.

Note: The User Mapping fields are preconfigured for most of the supported OIDC providers to minimize potential errors; use care when changing the settings. For the Standard OIDC option, contact your OIDC provider to obtain the details of the fields.

Table 10. User mapping settings

Field	Description
Username	The name of the field in the response token that contains the user's user name. Note: The Username field must be unique for this OIDC registry, because it identifies the user in the system and cannot be changed.
Email	The name of the field in the response token that contains the user's email address.
First name	The name of the field in the response token that contains the user's given name.
Last name	The name of the field in the response token that contains the user's surname.

Redirect URI

The Redirect URI section lists the endpoints to which the OIDC authorization server will redirect the authorization code. There is one endpoint for each API Connect organization type: Cloud administration, Provider organization, and Consumer organization. The redirect endpoint is required when a user registers their application with the OIDC provider. For example, if this OIDC user registry is used by a provider organization, the user must register the provider organization's redirect endpoint with the OIDC provider. These read-only fields are provided for you to copy the endpoint values as required.

Note: If the Developer Portal is publicly accessible and you select the `proxy_redirect` option, you must configure your OIDC provider to use the following redirect URI:

- URI path: `/ibm_apim/oidcredirect`
- Full URL example: `https://<your-developer-portal-domain>/ibm_apim/oidcredirect`

Where:

`<your-developer-portal-domain>` is the actual hostname of your public-facing Developer Portal; for example, `developer.example.com`.

This configuration ensures that the OIDC provider can correctly redirect authenticated users back to the Developer Portal as part of the login flow.

Enabling the OIDC user registry

Complete the following steps to enable the new user registry for Cloud Manager, API Designer, or both.

1. On the navigation pane, click Settings.
2. Click User Registries > Edit.
3. Click Edit in the section that corresponds to the application for which you are enabling the new user registry.
4. Select the new OIDC user registry.
5. When you have finished enabling the registry, click Save.

Using the CLI to configure an OIDC user registry

Use the developer toolkit CLI to configure a shared OIDC user registry when multi-factor authentication (MFA) is required.

Configure an OIDC user registry by first defining the registry details in a configuration file. You then use a CLI command to create the registry, passing the configuration file as parameter. To make the registry available to the Developer Portal, you must enable the registry in the associated catalog.
Note:

- An OIDC registry cannot be used to secure APIs on the gateway.
- If you are using an OIDC user registry for login, The Management server handles the interaction with the third-party OIDC provider. The management server is considered the application from the perspective of the third-party OIDC provider. Therefore, your OIDC redirect endpoint on the management server, which the third-party authorization server uses to send the token, must be accessible to the OIDC provider. To ensure login functions, you must allow access if your API Connect environment is secured behind a firewall. This is true for user login on both API Manager and Cloud Manager.
- If OIDC user registry is used for consumer login at the Developer Portal and Developer Portal is in the DMZ, you can use the **`proxy_redirect`** property. This allows the Developer Portal to act as the endpoint for proxying communication between the OIDC provider and API Connect.
- When you register your application with the third-party OIDC provider, you are required to supply the associated OIDC redirect URI, https://consumer.mycompany.com/consumer-api/oauth2/redirect for example. However, you cannot access this information until you create your OIDC user registry in API Connect. First, register your application without this information and then update it later, as detailed in the instructions on this page.

Logging in to the Management server

Before you can create an OIDC user registry, you must log in to your management server from the CLI. Use the following command:

```
apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
```

You can determine which identity provider to use in the **`--realm`** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
```

For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **`title`** value should enable you to determine which identity provider to use; you can then copy the corresponding **`--realm`** parameter directly from the displayed **`realm`** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **`default-idp-1`**.
For full details of the **`apic login`** command, see Logging in to a management server.

Defining your OIDC registry configuration

Define the configuration of your OIDC user registry in a YAML file. At a minimum, the YAML file must include the settings from the following list. For additional settings, see the tables provided with the UI version of the procedure in this topic.

```
title: registry_title
integration_url: oidc_integration_url
case_sensitive: case_sensitivity_setting
email_required: true_or_false
email_unique_if_exist: true_or_false
configuration:
  client_id: 'app_client_id'
  client_secret: 'my-client-secret'
  provider_type: oidc_provider_type
```

where:

- *registry_title* is your chosen descriptive title for the user registry.
- *oidc_integration_url* is the OIDC integration URL in your API Connect configuration. You can determine the OIDC integration URL by using the following CLI command:

  ```
  apic integrations:list --server mgmt_endpoint_url --subcollection user-registry
  ```

- *case_sensitivity_setting* determines whether your user registry is case-sensitive. Valid values are:
  - **`true`**
  - **`false`**

  To ensure proper handling of user name capitalization, ensure that your case-sensitivity setting here matches the setting on the backend OIDC provider:
  - Only set **`case_sensitive`** to **`true`** if the backend OIDC provider supports case-sensitivity.
  - Set **`case_sensitive`** to **`false`** if the backend OIDC provider does not support case-sensitivity.

  Note: After at least one user has been added to the registry, you cannot change this setting.
- *email_required* determines whether an email address is required as part of the user onboarding process. Valid values are:

    - `true`
    - `false`

  If set to `true`, the source identity provider must supply the email address as part of the authentication process during onboarding.
  Note: An email address is not required by default for onboarding to the Cloud Manager or the API Manager, but it is required for onboarding to the Developer Portal.
- *email_unique_if_exist* determines whether email addresses must be unique within the user registry. Valid values are:
    - `true`
    - `false`

  Note: Every account in the Developer Portal, including across different user registries for the same site, must have a unique email address, including the site Admin account.
- *app_client_id* is the client ID of the application that is registered with the OIDC server, and must be in string format.
- *my-client-secret* is the client secret of the application that is registered with the OIDC server, and must be in string format.
- *oidc_provider_type* is the type of OIDC provider; specify one of the following values:
    - `facebook`
    - `github`
    - `google`
    - `linkedin`
    - `slack`
    - `twitter`
    - `windows_live`
    - `standard`

      Note:
        - Use the `twitter` provider type if your OIDC provider is X (formerly known as Twitter).
        - Use the `standard` provider type for any OIDC provider that is compliant with the OIDC standard.
          If the provider type is `standard`, you must include the following additional properties in the `configuration` section of your YAML file:

          ```
          authorization_endpoint: 'oidc_auth_endpoint'
          token_endpoint:
            endpoint: 'oidc_token_endpoint'
          ```

          where:
            - *oidc_auth_endpoint* is the authorization endpoint on the OIDC server, and must be in string format.
            - *oidc_token_endpoint* is the token endpoint on the OIDC server, and must be in string format.

Default OIDC configurations

For each OIDC provider type, API Connect assumes a default configuration, but you can override the default configuration properties in your YAML file.

Note: Endpoints are subject to change; when you create a registry you must verify the default endpoint provided by API Connect.
API Connect makes the best effort to update endpoints for the known OIDC user registry types. However the OIDC provider can change the endpoint at any time. It is the customer's responsibility to confirm that the endpoints provided by API Connect are supported by the OIDC provider and to update the OIDC configuration as needed.

The default configurations are as follows:

- Facebook

  ```
  authorization_endpoint: 'https://www.facebook.com/v3.1/dialog/oauth'
  token_endpoint:
    endpoint: 'https://graph.facebook.com/v3.1/oauth/access_token'
  userinfo_endpoint:
    endpoint: 'https://graph.facebook.com/me'
  scope: email public_profile
  field_mapping:
    username: email
    email: email
    last_name: last_name
    first_name: first_name
  ```

- GitHub

  ```
  authorization_endpoint: 'https://github.com/login/oauth/authorize'
  token_endpoint:
    endpoint: 'https://github.com/login/oauth/access_token'
  userinfo_endpoint:
    endpoint: 'https://api.github.com/user'
  scope: 'read:user user:email'
  field_mapping:
    username: login
    email: email
    last_name: name
    first_name: name
  ```

- Google

  ```
  authorization_endpoint: 'https://accounts.google.com/o/oauth2/v2/auth'
  token_endpoint:
    endpoint: 'https://www.googleapis.com/oauth2/v4/token'
  scope: openid profile email
  field_mapping:
    username: email
    email: email
    last_name: family_name
    first_name: given_name
  ```

- LinkedIn
  Some settings differ between the legacy configuration and the newer configuration. Be sure to use the correct settings for the LinkedIn protocol that you are using.

    - New OIDC protocol:

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
  credential_location: form_body
  field_mapping:
    email: email
    username: name
    first_name: given_name
    last_name: family_name
  scope: openid profile email
  token_endpoint:
    endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
  userinfo_endpoint:
    endpoint: 'https://api.linkedin.com/v2/me'
```

- Legacy OIDC protocol:

```
authorization_endpoint: 'https://www.linkedin.com/oauth/v2/authorization'
token_endpoint:
  endpoint: 'https://www.linkedin.com/oauth/v2/accessToken'
userinfo_endpoint:
  endpoint: 'https://api.linkedin.com/v2/me'
email_endpoint:
  endpoint: 'https://api.linkedin.com/v2/emailAddress?q=members&projection=(elements*(handle~))'
scope: r_liteprofile r_emailaddress
field_mapping:
  username: emailAddress
  email: emailAddress
  last_name: localoizedLastName
  first_name: localizedFirstName
credential_location: form_body
```

- Slack

```
authorization_endpoint: 'https://slack.com/oauth/authorize'
token_endpoint:
  endpoint: 'https://slack.com/api/oauth.access'
userinfo_endpoint:
  endpoint: 'https://slack.com/api/users.identity'
scope: identity.basic identity.email
field_mapping:
  username: user.email
  email: user.email
  last_name: user.name
  first_name: user.name
```

- X (formerly known as Twitter)

```
request_endpoint: https://api.x.com/oauth/request_token'
authorization_endpoint: https://api.x.com/oauth/authenticate'
token_endpoint:
    endpoint: 'https://api.x.com/oauth/access_token'
userinfo_endpoint:
    endpoint: 'https://api.x.com/1.1/account/verify_credentials.json'
oauth_signature_method: 'HMAC-SHA1'
field_mapping:
    email: email
    first_name: name
    last_name: name
    username: screen_name
```

- Windows Live

```
authorization_endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/authorize'
token_endpoint:
  endpoint: 'https://login.microsoftonline.com/common/oauth2/v2.0/token'
scope: openid offline_access profile email
field_mapping:
  email: email
  username: preferred_username
  first_name: name
  last_name: name
```

- Standard

```
response_type: code
scope: openid
field_mapping:
  username: sub
  email: email
  last_name: family_name
  first_name: given_name
credential_location: auth_header
```

  Although this is the default configuration for the **standard** provider type, you should contact your OIDC provider to obtain the details of the fields that you need to define.

Creating your OIDC user registry

To create your OIDC user registry, use the following CLI command:

```
apic user-registries:create --server mgmt_endpoint_url --org admin oidc_config_file
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.

- *organization_name* is the value of the **name** property of your provider organization.
- *oidc_config_file* is the name of the YAML file that defines the configuration of your OIDC user registry.

On completion of the registry creation, the command displays the following summary details:

```
registry_name registry_url
```

By default, the *registry_name* is derived from the **title** property in the configuration YAML file but you can override this by including a **name** property in the file. The *registry_url* is an internal URL that API Connect assigns to the registry.
After you have created your OIDC user registry, you must update your application registration with the third party OIDC provider to include the OIDC redirect URI; you can obtain this information by using the following command, which displays the details of the registry in the command window:

```
apic user-registries:get --server mgmt_endpoint_url --org organization_name registry_name --output -
```

The required **oidc_redirect_uri** value is in the **consumer:** section; for example:

```
consumer:
  oidc_redirect_uri: https://consumer.mycompany.com/consumer-api/oauth2/redirect
```

Enabling your OIDC registry in a Catalog

If you want to make your OIDC registry available for onboarding and authenticating Developer Portal users, you must enable it in the Catalog that is associated with that Developer Portal. Complete the following steps:

1. Determine the URL of your OIDC user registry by using the following command:

   ```
   apic user-registries:list --server mgmt_endpoint_url --org admin
   ```

2. Log in to the Management server as a member of a provider organization; enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   For full details of the **apic login** command, see Logging in to a management server.
3. Enter the following command (the terminating hyphen character means that the command takes input from the command line):

   ```
   apic configured-catalog-user-registries:create --server mgmt_endpoint_url --org organization_name --catalog catalog_name -
   ```

   where *catalog_name* is the value of the `name` property of the required Catalog. The command returns

   ```
   Reading CONFIGURED_CATALOG_USER_REGISTRY_FILE arg from stdin
   ```

4. Enter the following data, followed by a new line:

   ```
   user_registry_url: oidc_registry_url
   ```

   where *oidc_registry_url* is the URL of your OIDC registry, obtained in step 1.
5. Press **CTRL D** to terminate the input.

For details of all the **apic user-registries** and **apic configured-catalog-user-registries** commands, see the toolkit CLI reference documentation.

You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Setting visibility for a user registry

The visibility setting determines which provider organizations can access a resource, for example, user registries.

Before you begin

You must complete the following tasks:

- Creating an availability zone
- Registering a gateway service

About this task

The user registry visibility setting controls which provider organizations are able to use that registry for authenticating Developer Portal users, or for securing APIs. For details on how to specify the user registries that can be used for authenticating users of the Cloud Manager and API Manager user interfaces, see Selecting user registries for Cloud Manager and API Manager.

Procedure

Follow these steps to set the visibility for the resources (user registries) in your on-premises cloud:

1. In the Cloud Manager, click  Resources.
2. Select User Registries as the resource to view.
3. From the list of user registries, choose Edit visibility from the actions menu next to the name of the user registry you are working with.
4. Select the visibility setting for the user registry. The options are:
   - Private - the user registry is not visible and cannot be used by any provider organization
   - Public - the user registry is visible and can be used by all provider organizations
   - Custom - the user registry is visible only to the provider organizations designated by you
5. For Custom visibility, select the provider organizations that you want to have access to the user registry.

6. Click Make visible to complete the operation.

Results

For Private, the user registry cannot be used by any provider organizations. For Public, the user registry can be used by all provider organizations. For Custom, the user registry can be used by the provider organizations that you designate.

Deleting a user registry

As the Cloud Manager administrator, you can delete user registries.

About this task

Complete the following steps to delete a user registry. All users within the user registry will be deleted. The pre-configured user registries (API Manager Local User Registry and Cloud Manager Local User Registry) may not be deleted. Any user registry marked as the Default in Settings > User Registries also may not be deleted.

One of the following roles is required to delete a user registry:

- Administrator
- Owner

Procedure

1. In the Cloud Manager, click  .
2. Select User Registries to see the list of current user registries in your cloud.
3. Choose Delete from the overflow menu that is adjacent to the user registry you want to delete.
4. Optionally, you can delete multiple user registries by marking the checkboxes and selecting Delete Selected User Registries from the overflow menu for the list.
5. Confirm the deletion.

Results

The user registry is deleted and removed from the User Registries list in Cloud Manager. All user accounts contained in the user registry are deleted.

Removing a user from a user registry

As an API Connect user, you can remove yourself from an API Connect user registry. As an administrative user, you can remove other users from an API Connect user registry.

For details on how to remove a user from a user registry, see the following subtopics:

- **Removing yourself from a user registry**
  As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.
- **Removing another user from a user registry**
  You can remove a user from an API Connect user registry by using the developer toolkit CLI.

Removing yourself from a user registry

As an API Connect user, you can remove yourself from the API Connect user registry in which you were registered, by using the developer toolkit CLI.

Before you begin

You cannot remove yourself from a user registry if you are a member of a provider organization. Before removing yourself from a user registry, ensure that you have been deleted from any provider organizations. For more information, see Removing a user from an organization.

Procedure

1. Log in to the management server as the user that you want to remove.
   The format of the login command depends on whether you are a user in the Cloud Manager admin organization, or you are a user in a provider organization.

   If you are a Cloud Manager admin user, enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   If you are a provider organization user, enter the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm provider/identity_provider
   ```

   If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields title,realm
```

where *scope* has the value **admin** or **provider** depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**, and the default API Manager Local User Registry for login as a member of a provider organization is **default-idp-2**.
For full details of the **apic login** command, see Logging in to a management server.

Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and you have access to both, when you remove yourself from the user registry you will lose access to both user interfaces regardless of which organization you log in to.

2. Remove yourself from the user registry. Enter the following command:

```
apic me:delete --server mgmt_endpoint_url
```

For example:

```
apic me:delete --server platform-api.myserver.com.com
```

The command confirms successful removal by returning the details of the deleted user; for example:

```
user1    [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
```

Removing another user from a user registry

You can remove a user from an API Connect user registry by using the developer toolkit CLI.

Before you begin

To complete this task, you must have Administrator access to your API Connect cloud, or be the owner of a provider organization, depending on the scope of the user registry.

You cannot remove a user from a user registry if that user is a member of the Cloud Manager admin organization, a provider organization, or a consumer organization, and that user registry is used for the associated login. Before removing a user from a user registry, ensure that they have been deleted from any organizations for which that user registry is used for login. For more information, see Deleting a member or Removing a user from an organization.

Procedure

1. Log in to the management server.
   - If the user registry is defined at the cloud administration level, and therefore available to all provider organizations, you must log in as a member of the Cloud Manager admin organization.
   - If the user registry is defined at a provider organization level, and therefore specific to that provider organization, you must log in as the organization owner.

   For full details of the **apic login** command, see Logging in to a management server.

   Note: If the same user registry is used for both the Cloud Manager and API Manager user interfaces, and the user has access to both, when you remove them from the user registry they will lose access to both even though you are logging in to the admin organization.
2. Identify the name of the user registry from which you want to remove the user. Enter the following command:

```
apic user-registries:list --server mgmt_endpoint_url --org organization_name
```

where *organization_name* has the value **admin** if you are logged in as a member of the Cloud Manager admin organization, or is the name of the provider organization if you are logged in as an organization owner.
For example:

```
apic user-registries:list --server platform-api.myserver.com.com --org admin
```

The command returns a list of all user registries, with the registry name displayed first; for example:

```
api-manager-lur     https://platform-api.myserver.com.com/api/user-registries/3283e897-1d23-4fac-acf5-
0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245
cloud-manager-lur   https://platform-api.myserver.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/3adbf524-
cd74-4051-99c0-89ce5ffcc9c0
my-ldap             https://platform-api.myserver.com/api/user-registries/3283e897-1d23-4fac-acf5-0193d0b2c1b5/29eae413-
cd74-4051-99c0-89ce5ffcc9c0
```

3. Identify the name of the user, from the required user registry, that you want to remove. Enter the following command:

```
apic users:list --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
```

For example:

```
apic users:list --server platform-api.myserver.com.com --org admin --user-registry my-ldap
```

The command returns a list of all users in the user registry, with the user name displayed first; for example:

```
user1     [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
user2     [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/12f1aa82-d9f0-4670-99f1-7500d1fb6583
```

4. Remove the required user from the user registry. Enter the following command:

   ```
   apic users:delete user_name --server mgmt_endpoint_url --org organization_name --user-registry user_registry_name
   ```

   For example:

   ```
   apic users:delete user1 --server platform-api.myserver.com.com --org admin --user-registry my-ldap
   ```

   The command confirms successful removal by returning the details of the deleted user; for example:

   ```
   user1    [state: enabled]   https://platform-api.myserver.com.com/api/user-registries/32830897-1d23-4fac-acf5-
   0193d0b2c1b5/4438937a-6ad0-4eaa-9163-820888ac6245/users/040adb11-e9a4-4d93-9c2e-62a974da0689
   ```

TLS profiles overview

Create TLS profiles to manage the TLS communication between subsystems, external systems, and your API invocation endpoint.

Mutual TLS is used to secure communication between API Connect subsystems, and TLS is used for communication with external systems such as email servers.

If you do not want to use mTLS for inter-subsystem communication, you can use JWT instead:

- Use JWT instead of mTLS on VMware.
- Use JWT instead of mTLS on Kubernetes and OpenShift.

Some of the API Connect TLS configuration is managed in the Cloud Manager UI, and is covered by this topic. The rest of the API Connect TLS configuration, which includes the management REST API endpoints and portal site certificates, are managed at the infrastructure level and covered in these topics:

- VMware: TLS certificate concepts and operations
- Kubernetes and OpenShift: API Connect certificates

The API Connect TLS configuration that is managed in the Cloud Manager UI covers the following areas:

- Client certificates for inter-subsystem communication: Communication from your management subsystem to your portal, analytics, and gateway services.
- API invocation endpoint. The certificates that callers of your published APIs see.
- TLS profiles that you create for use in API definitions.
- Communication with third-party systems.

When you install API Connect, default TLS profiles are created. If all of your API Connect subsystems are in the same environment (same Kubernetes or OpenShift namespace, or the same VMware infrastructure and project directory), then you can use these default TLS profiles to register your portal, gateway, and analytics services with your management subsystem.
Note: If you do not want to use the default TLS profiles, it is recommended to create new TLS profiles to use instead. Do not edit the default TLS profiles.
Two types of TLS profile can be configured in the Cloud Manager UI:

- Client profiles are used to define the client certificate and ciphers that are used for making client connections to other systems.
- Server profiles are used to define the server certificate and ciphers that are used for securing server endpoints. The only server profile that is created automatically (during installation) is the **`Default TLS server profile`**, which is used to secure the API invocation endpoint.

The components of a TLS Profile are:

- TLS version indicates the version of the Transport Layer Security Protocol that is used by the profile. Options are TLS versions 1.0, 1.1, 1.2, and 1.3.
- Support for mutual authentication and renegotiation for server profiles.
- Support for weak server connections and Server Name Indication for client profiles.
- Supported cipher suites.
- Keystores, which contain the TLS keys that are used for initiating client connections.
- Truststores, which contain the public keys to validate your analytics, portal, and gateway subsystems, and for trusted third-party services that you integrate with.

Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

TLS profiles created during installation

The following table shows the TLS profiles that API Connect creates during installation. You can use these profiles when you register your portal, gateway, and analytics services if your deployment is:

- On OpenShift or Kubernetes, and all subsystems are installed in the same environment and namespace.
- On VMware, and all subsystems are managed from the same project directory.

Table 1. TLS profiles

TLS profile name	Description
Default TLS server profile	For testing and demonstration purposes, you can specify this profile as the TLS server profile when you register your gateway service. For production deployments, best practice is to create your own TLS server profiles and not use the **`Default TLS server profile`**.
Default TLS client profile	You can use this profile as a client profile for communication between the management subsystem and any other system. This profile is set to trust everything (**`insecure server connections`** is set to **`true`**), and has no keystore or truststore. Use this profile only for testing and demonstrations.

TLS profile name	Description
Analytics ingestion TLS client profile	Default client profile for use when the management or gateway subsystem communicates with the analytics service: • From the management subsystem to the analytics subsystem, when you register the analytics service and when querying for analytics data. • From the gateway to the analytics subsystem, when the gateway sends API event data to the analytics subsystem. Select this profile when you register the analytics service. Note: If you want to use a different client certificate for your analytics service, do not edit this client profile, create a new profile instead.
Portal Director TLS client profile	Default client profile when the management subsystem communicates with the developer portal subsystem. Select this profile when you register the portal service. Note: If you want to use a different client certificate for your portal service, do not edit this client profile, create a new profile instead.
Gateway management client TLS client profile	Default client profile when the management subsystem communicates with the gateway subsystem. Select this profile when you register the gateway service. Note: If you want to use a different client certificate for your gateway service, do not edit this client profile, create a new profile instead.

Keystores created during installation

The following table shows the keystores that API Connect creates during installation:

Table 2. Keystores

Keystore name	Description
Analytics ingestion	Used by the **`Analytics ingestion TLS client profile`**, this keystore contains the client certificate that is used for connecting to the analytics subsystem's ingestion endpoint. This certificate is used by the management subsystem when it initiates communication with the analytics subsystem, and by the gateway when it sends API event data to the analytics subsystem. Kubernetes and OpenShift installations: The default client certificate in this keystore is set from the Kubernetes certificate analytics-ingestion-client. VMware installations: The default client certificate in this keystore is set from the certificate analytics-ingestion-client. Do not edit this keystore. If you want to use a different client certificate for analytics ingestion, then create a new client profile and keystore for it.
Portal director	Used by the **`Portal Director TLS client profile`**, this keystore contains the client certificate that is used when the management subsystem initiates communication with the portal subsystem. Kubernetes and OpenShift installations: The default client certificate in this keystore is set from the Kubernetes certificate portal-admin-client. VMware installations: The default client certificate in this keystore is set from the certificate portal-client.
Gateway mgmt	Used in the **`Gateway management client TLS client profile`**, this keystore contains the client certificate that is used when the management subsystem initiates communication with the gateway. Kubernetes and OpenShift installations: The default client certificate in this keystore is set from the Kubernetes certificate gateway-client-client or gw-dr-client.
Default TLS server keystore	Used in the **`Default TLS server profile`**, this keystore contains the server certificate that secures the API invocation endpoint on your gateway. Note: It is recommended to use the **`Default TLS server profile`** only for testing and demonstrations. Best practice is to create a new keystore and server profile for your API invocation certificate.
Default keystore for id_token signing key	Used for signing ID tokens that API Connect generates. You must update the certificate in this keystore manually before it expires. Upload a replacement certificate in the Cloud Manager UI.
Default keystore for self signed token signing key	Used for signing self-signed tokens that API Connect generates. You must update the certificate in this keystore manually before it expires. Upload a replacement certificate in the Cloud Manager UI.
Default keystore for temporary token signing key	Used for signing temporary tokens that API Connect generates. You must update the certificate in this keystore manually before it expires. Upload a replacement certificate in the Cloud Manager UI.
Default keystore for access_token signing key	Used for signing access tokens that API Connect generates. You must update the certificate in this keystore manually before it expires. Upload a replacement certificate in the Cloud Manager UI.

Truststores created during installation

The following table shows the truststores that API Connect creates during installation:

Table 3. Truststores

Truststore name	Description
Analytics ingestion	Used by the **`Analytics ingestion TLS client profile`**, this truststore contains the **`root-ca`** and **`ingress-ca`**, with which the management subsystem validates the certificate that the analytics subsystem presents.
Portal director	Used by the **`Portal Director TLS client profile`**, this truststore contains the **`root-ca`** and **`ingress-ca`**, with which the management subsystem validates the certificate that the portal subsystem presents.
Gateway management client truststore	Used by the **`Gateway management client TLS client profile`**, this truststore contains the **`management-ca`** certificate on VMware and **`ingress-ca`** on Kubernetes and OpenShift, with which the management subsystem validates the certificate that the gateway subsystem presents.

- **Creating a TLS server profile**
  Create a TLS server profile in the Cloud Manager UI to secure the API invocation endpoint on your registered gateways.

- **Creating a TLS client profile**
  Create TLS client profiles in the Cloud Manager UI to secure client connections in your API Connect environment.
- **Creating a keystore**
  Create a keystore by uploading a public and private key pair.
- **Creating a truststore**
  Create a truststore that contains a list of certificates that your TLS profile trusts.
- **Managing TLS profiles, keystores, and truststores**
  TLS profiles, keystores, and truststores can be created, updated, and deleted in the Cloud Manager UI.
- **Using OpenSSL to generate and format certificates**
  Use OpenSSL to create your own self-signed certificates, or convert PEM certificate files to P12 files.

Creating a TLS server profile

Create a TLS server profile in the Cloud Manager UI to secure the API invocation endpoint on your registered gateways.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

Create the keystores and truststores for your TLS server profile.

One of the following roles is required to configure TLS server profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

About this task

When you register a gateway service, you select a TLS server profile that contains the TLS certificate that is used to secure the API invocation endpoint on the gateway. It is recommended to create your own TLS server profile to secure your API invocation endpoints. The procedure in this topic covers how to create this TLS server profile.

Procedure

Complete the following steps to create a TLS server profile:

1. In the Cloud Manager, click  Resources.
2. Select Crypto Material.
3. Click Create in the TLS server profile table.
4. Enter the fields to configure the TLS server profile:

Field	Description
Title	Enter a title for the profile.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Version	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, **`MyProfile 1.0`** and **`MyProfile 1.1`**.
Summary	Enter a description of the profile.
Protocols	Select one or more supported TLS protocol versions. The default is 1.2 and 1.3.
Mutual Authentication	Determines the level of two-way authentication for the server profile. In two-way authentication, the server responds to a client by sending a request for the client certificate. • None (default) No support for mutual authentication. • Request Enable this option to request client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the certificate is not checked on the gateway. • Require Enable this option to require client authentication during the TLS handshake. When the application sends the request, the gateway requests that the application sends the certificate. If the client does not send the certificate, the TLS handshake fails and the request is blocked.
Limit Renegotiation	Client-initiated renegotiation allows the connection to be retried. The default is to prevent renegotiation. Remove the checkmark to allow renegotiation.
Keystore	A keystore is a repository that contains a public and private key pair that are used to secure the endpoint. Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

Field	Description
Truststore	A truststore is a repository that contains TLS certificates which the endpoint secured by your TLS server profile trusts. When a client connects to your endpoint, it must present a certificate that is signed by a certificate in your truststore. Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.
Ciphers	Cipher suites are encryption algorithms that are used to secure the TLS communication. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, **all** the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are **not** added to the list of ciphers supported by the profile.

5. Click Save.

Creating a TLS client profile

Create TLS client profiles in the Cloud Manager UI to secure client connections in your API Connect environment.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

One of the following roles is required to configure TLS client profiles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

A TLS client profile defines the TLS version, keystore, truststore, and ciphers used when making a client connection to a TLS secured endpoint.

Procedure

Complete the following steps to create a TLS client profile:

1. In the Cloud Manager, click Resources.
2. Select Crypto Material.
3. Click Create in the TLS client profile table.
4. Enter the fields to configure the TLS Client Profile:

Field	Description
Title	Enter a title for the profile.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Version	Assign a version number for the profile. Using version numbers allows you to create multiple server profiles with the same name and different configurations, for example, **`MyProfile 1.0`** and **`MyProfile 1.1`**.
Summary	Enter a description of the profile.
Protocols	Select one or more supported TLS protocol versions. The default is 1.2 and 1.3.
Server Connection	Specify whether to support weak or insecure credentials. • Allow insecure server connections - Insecure server connections can mean connections that use certificates that are self-signed, expired, corrupted, or from an unknown or untrusted source. Check this box to allow the connection to proceed with an insecure connection. The default is to not allow insecure server connections. • Support Server Name Indication (SNI) - Check this box to enable SNI. SNI allows support for multiple certificates presented on the same IP address using different hostnames. The client profile sends the name of a virtual domain as part of the TLS negotiation. The default is to enable SNI.
Keystore	A keystore is a repository that contains public and private key pairs. The keystore has the public key that the client presents when it initiates communication with a TLS secured endpoint. Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.
Truststore	A truststore is a repository that contains verified public keys. Truststores contain the list of certificates that your TLS client profile trusts. Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

Field	Description
Ciphers	Cipher suites are encryption algorithms that are used to secure the TLS communication. Select the ciphers that the profile supports. Note: The TLS 1.3 ciphers are clearly indicated. If you select TLS version 1.3 as one of the protocols for the profile but do not select any TLS 1.3 ciphers, **all** the TLS 1.3 ciphers are added to the list of ciphers supported by the profile. If you do not select TLS version 1.3 but select one or more TLS 1.3 ciphers, those ciphers are **not** added to the list of ciphers supported by the profile.

Defining elliptic curve cryptographic schemes for a TLS client profile

You define the elliptic curve cryptographic schemes for a TLS client profile by using the developer toolkit CLI.

About this task

To define elliptic curve cryptographic schemes for a TLS client profile, you include **`elliptic_curve_auto_negotiation`** and **`elliptic_curve`** properties in a YAML file definition for the TLS client profile. The **`elliptic_curve`** property lists the required elliptic curve cryptographic schemes. For example:

```
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - secp521r1
  - secp384r1
  - prime256v1
```

You then use the developer toolkit CLI to create the TLS client profile in API Connect.

When **`elliptic_curve_auto_negotiation`** is set to **`true`**, the system negotiates the Elliptic-curve Diffie-Hellman (ECDH) key agreement automatically with its peer, and any **`elliptic_curve`** property settings are ignored.

The following example shows a complete YAML file for a TLS client profile:

```
type: tls_client_profile
name: my-tls-client-profile
version: 1.0.0
title: My TLS client profile
protocols:
  - tls_v1.2
ciphers:
  - ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
elliptic_curve_auto_negotiation: false
elliptic_curve:
  - sect163k1
insecure_server_connections: false
server_name_indication: true
```

Note:

- The **`elliptic_curve_auto_negotiation`** option is not supported by any of the API Connect gateway types. If the TLS client profile is targeted for an API Connect gateway; this setting is ignored by the gateway.
- The elliptic curve cryptographic schemes shown in each row of the following table are equivalent. However, API Connect recognizes only one or the other depending on how the TLS profile is used, as indicated in the table.

  Table 1.

API enforcement on the gateway	API Connect server access security
secp192r1	prime192v1
secp256r1	prime256v1

  Therefore, if you want to use either of these schemes and are unsure whether you are targeting the TLS client profile to the API Connect gateway for API enforcement, whether you are using it to secure user access to the API Connect servers, or whether it will be used for both purposes, specify both equivalent schemes; API Connect will simply ignore the non-relevant scheme. For example:

```
elliptic_curve:
       .
       .
       .
  - secp256r1
  - prime256v1
       .
       .
       .
```

Procedure

Complete the following steps to create a TLS client profile with elliptic curve cryptographic schemes defined:

1. Create a YAML file definition for your TLS client profile, with the required **`elliptic_curve`** property.
2. Log in to the management server from the developer toolkit CLI. Log in either as a member of the cloud administration organization or as a member of a provider organization, depending on where you want to create the TLS client profile. For details, see Logging in to a management server.
3. Create the TLS client profile by using the following command:

   ```
   apic tls-client-profiles:create --server mgmt_endpoint_url --org organization_name tls_client_profile_yaml_file
   ```

   where:
   - *mgmt_endpoint_url* is the platform API endpoint URL, and is the same as that which was used when you logged in at step 2.
   - *organization_name* is either **`admin`**, for the cloud administration organization, or the name of your provider organization, and is the same as that which was used when you logged in at step 2.
   - *tls_client_profile_yaml_file* is the name of the YAML file that contains the definition for your TLS client profile.

   Note: When you install IBM® API Connect, the API Connect gateway has a pre-supplied default TLS client profile that is used for API enforcement if you do not configure a TLS client profile; you cannot configure this default TLS client profile on the gateway.
   For reference details of all the **`apic tls-client-profiles`** commands, see the toolkit CLI reference documentation.

   You can also complete the operations described in this topic by using the API Connect REST APIs; see the API Connect REST API documentation.

Creating a keystore

Create a keystore by uploading a public and private key pair.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

Your private and public keys must be in PEM or P12 formatted files.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.
One of the following roles is required to configure keystores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

API Connect provides pre-configured keystores that are created at installation, and which can be used for testing and demonstration purposes. For production deployments, it is recommended to create new keystores that contain your own TLS certificates.
Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

Procedure

Complete the following steps to create a TLS client profile:

1. In the Cloud Manager, click  Resources.
2. Select Crypto Material.
3. Click Create in the keystore table.

Field	Description
Title	Enter a title for the keystore.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Summary	Enter a brief description.
Private key & public key: Step 1: Upload private key	Upload the file that contains the private key certificate. If necessary, you can click Browse to locate the file. If the file contains both the private and public keys, upload it in Step 1. Private and public keys are always uploaded in pairs, either in a single file or separate files. Keys can be in PEM or P12 format, and must contain all intermediate certificates (up to a maximum of 10).
Private key password	If the private key has a password, then enter it here.
Private key & public key: Step 2: Upload public key	If the public key is contained in a separate file, upload it in Step 2. Private and public keys are always uploaded in pairs, either in a single file or separate files. Keys can be in PEM or P12 format, and must contain all intermediate certificates (up to a maximum of 10).

4. Click Save.
   Note: Uploaded keys and certificates cannot be download from API Connect.

Creating a truststore

Create a truststore that contains a list of certificates that your TLS profile trusts.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

Your public keys must be in PEM or P12 formatted files.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.
One of the following roles is required to configure truststores:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: Manage` permissions

About this task

API Connect provides pre-configured truststores that are created at installation, and which can be used for testing and demonstration purposes. For production deployments, it is recommended to create new truststores with your own TLS certificates.
Important: If you create your own TLS profiles, API Connect verifies certificates when you upload them, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expire.

Procedure

1. In the Cloud Manager, click  Resources.
2. Select Crypto Material.
3. Click Create in the truststore table.

Field	
Title	Enter a title for the truststore.
Name	The name is auto-generated and based on the title (with spaces and other URL unsafe characters replaced).
Summary	Enter a brief description.
Upload truststore certificates	Upload the file that contains the public key certificate.

4. Click Save.

Managing TLS profiles, keystores, and truststores

TLS profiles, keystores, and truststores can be created, updated, and deleted in the Cloud Manager UI.

Before you begin

Review the TLS profiles overview to understand the concepts of TLS profiles, keystores, and truststores, and the purpose of the default profiles that are created at installation.

To view TLS server profiles, keystores, and truststores, one of the following roles is required:

- Viewer
- Custom role with the `Settings: view` permissions

To view, create, edit, or delete TLS server profiles, keystores, and truststores, one of the following roles is required:

- Administrator
- Owner
- Topology Administrator

- Custom role with the `Settings: Manage` permissions

About this task

The Crypto Material section in the Cloud Manager UI contains the TLS profiles, keystores, and truststores configured for your cloud.

API Connect provides pre-configured keystores and truststores that are created at installation, and which can be used for testing and demonstration purposes. For production deployments, it is recommended to create new keystores and truststores with your own TLS certificates.
Important: Do not modify the default keystores and truststores that are created at installation.
If you create your own TLS profiles, keystores, and truststores, API Connect verifies all certificates you upload, but does not continuously monitor them for expiry. You are responsible for monitoring and updating your certificates before they expiry. Certificate expiration dates are displayed in the keystores and truststores that contain them.

Certificate files that you upload must be in PEM or P12 format.
Note: For information on generating TLS certificates and keys, see Using OpenSSL to generate and format certificates.

Procedure

1. In the Cloud Manager, click Resources.
2. Select Crypto Material.
3. From the Crypto Material section you can add, edit, and delete your TLS profiles, keystores, and truststores.
   - TLS server profiles. Configure the TLS profiles used to secure the API invocation endpoints on your gateways. If you want to update keys and certificates, then view the TLS server profile to identify the keystore and truststore that contains them.
   - TLS client profiles. Configure the TLS profiles used to initiate client connections to other systems. If you want to update keys and certificates, then view the TLS client profile to identify the keystore and truststore that contains them.

     You can manage the visibility of TLS client profiles for provider organization members. Select Edit visibility from the ⋮ options menu next to the name of the profile. The following visibility settings are available:
     - Private - the profile is visible only in the Cloud Manager UI and cannot be used by any provider organization.
     - Public - the profile can be used by all provider organizations.
     - Custom - the profile can be used by the provider organizations you specify.
   - Keystores. Upload the private and public key pairs that your TLS profiles use.

     The certificate's subject, finger print, and expiration date are displayed. Click > to view more certificate details.

     Note: You cannot download your uploaded keys and certificates from API Connect.
   - Truststores. Upload the certificates that your TLS profiles trust.
   - JWK sets. The JWK sets in the Crypto Material section are not related to TLS profiles. See the Config sync feature.

Using OpenSSL to generate and format certificates

Use OpenSSL to create your own self-signed certificates, or convert PEM certificate files to P12 files.

OpenSSL is an open source toolkit that can be used for generating and validating TLS certificates.

This topic covers how to generate a self-signed TLS certificate by using the OpenSSL toolkit, and how to convert certificates in PEM format to P12 format.

Creating a self-signed certificate with OpenSSL

Use the following command to create a private key and public certificate with OpenSSL:

```
openssl req -newkey rsa:2048 -nodes -keyout private_key.pem -x509 -days 365 -out public_certificate.pem
```

The OpenSSL command asks for the following information to create your private key and public certificate (example values shown):

- Country Name (2 letter code) []: US
- State or Province Name (full name) []: California
- Locality Name (eg, city) []: Sacramento
- Organization Name (eg, company) []: exampleorganization
- Organizational Unit Name (eg, section) []:
- Common Name (eg, fully qualified host name) []: gateway.exampleorganization.com
- Email Address []:

Common Name must be set to the fully qualified domain name of the system that uses the certificate. For static DNS, use the hostname or IP address set in your Gateway Cluster (for example. **`192.16.183.131`** or **`gateway.exampleorganization.com`**).

To review the generated public certificate run:

```
openssl x509 -text -noout -in public_certificate.pem
```

To combine the generated private_key and public_certificate PEM files into a password protected P12 file, run:

```
openssl pkcs12 -inkey private_key.pem -in public_certificate.pem -export -out certificate.p12
```

To validate a P12 file, run:

```
openssl pkcs12 -in certificate.p12 -noout -info
```

Creating PKCS#12 (P12) certificate from PEM files

PKCS#12 (P12) defines an archive file format for storing cryptographic objects as a single file. Use OpenSSL to create a password protected P12 file from your PEM files.

Prerequisites:

- Private key file. For example: private_key.pem.
- CA signed certificate. For example: public_certificate.pem.
- If you have intermediate certificates from your CA, concatenate them into a single .pem file to create a ca_chain.pem file:

  ```
  cat ca1.pem ca2.pem ca3.pem > ca_chain.pem
  ```

  the ca_chain.pem file should look like this:

  ```
  -----BEGIN CERTIFICATE-----
  MIIEpjCCA46gAwIBAgIQEOd26KZabjd+BQMG1Dwl6jANBgkqhkiG9w0BAQUFADCB
  ...
  lQX7CkTJn6lAJUsyEa8H/gjVQnHp4VOLFR/dKgeVcCRvZF7Tt5AuiyHY
  -----END CERTIFICATE-----
  -----BEGIN CERTIFICATE-----
  MIIEPDCCAySgAwIBAgIQSEus8arH1xND0aJ0NUmXJTANBgkqhkiG9w0BAQUFADBv
  ...
  -----END CERTIFICATE-----
  -----BEGIN CERTIFICATE-----
  MIIENjCCAx6gAwIBAgIBATANBgkqhkiG9w0BAQUFADBvMQswCQYDVQQGEwJTRTEU
  ...
  -----END CERTIFICATE-----
  ```

- If you have multiple end-entity (leaf) certificates in one file, then split them into separate files and create separate P12 files for each certificate.

Create the P12 file with the following OpenSSL command (if you don't have CA certificates to include, then omit `-CAfile <filename> -chain`):

```
openssl pkcs12 -inkey private_key.pem -in public_certificate.pem -export -out certificate.p12 -CAfile caChain.pem -chain
```

OAuth Provider overview

API Connect supports OAuth Specification 2.0, for both Native and Third party implementations.

Introduction to OAuth

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information. In API Connect, you can secure an API with OAuth.

In Cloud Manager, you configure both Native and Third party OAuth providers that can be made visible to selected Provider organizations. The OAuth Provider configuration is based on the OAuth 2.0 Specification, which is available at https://tools.ietf.org/html/rfc6749. Knowledge of the OAuth 2.0 specification is required to implement an OAuth Provider in API Connect.

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- **Configuring a native OAuth provider**
  Native OAuth providers are configured and managed by you within your cloud.
- **Configuring a third-party OAuth provider**
  Enter the secure endpoints to provide OAuth authentication from a third party.
- **Setting the visibility for OAuth providers**
  The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.
- **OAuth concepts for API Connect**

Configuring a native OAuth provider

Native OAuth providers are configured and managed by you within your cloud.

About this task

A native OAuth provider object provides settings for OAuth processing operations such as generating and validating OAuth tokens. An OAuth provider object is referenced by an OAuth security definition to protect an API. When a native OAuth provider is used, the OAuth operations are performed natively by API Connect.

Every OAuth provider object has a backing API. Your configuration here automatically updates the OpenAPI document of the API. You can edit the OpenAPI document directly by navigating to the Resources > OAuth Providers page, selecting your OAuth provider, then clicking API Editor.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the **`oauth-provider-settings-ref`** field in each OAuth assembly action.

When a published API references an OAuth provider object, the backing API is automatically made available in the gateway.

Token requests and client_id checks:
If you are calling an OAuth endpoint, the sequence of **`client_id`** checks in the token request is as follows:

1. Check both body and query.
   - If found in only the body, validate and return a **`200`** or appropriate return code.
   - If found in only the query, return a **`wrong location`** error.
   - If found in both the body and the query, return a **`more than one location`** error.
2. When not found in the body or the query, check the **`Authorization`** header.
   - If found in this header, validate and return a **`200`** or appropriate return code.
3. Not found, return the appropriate error and code.

The best location for the **`client_id`** is in the request body.
One of the following roles is required to configure a native OAuth provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note:

- The OAuth provider logs analytics data for failure cases, but does not log successful cases. Activity log policies that call for logging of analytics data upon success do not apply for the OAuth provider.
- You must ensure the OAuth Provider is configured in the Sandbox Catalog before using the OAuth Provider in a non-Sandbox Catalog.

Procedure

OAuth provider configuration uses a series of screens. The first set of screens controls a basic OAuth provider configuration. Perform the following steps to configure a native OAuth Provider for your cloud:

1. In the Cloud Manager, click Resources.
2. Click OAuth Providers > Add > Native OAuth provider.
   a. Complete the following parameters for the first screen, then click Next.

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
Gateway Type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. In the next screen, enter the following additional configuration parameters, then click Next.

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to login to account

Field	Description
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.
Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step. • Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security. • Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code." • Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients. • API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token. Note: To use the Resource owner - JWT option, complete the following steps: • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT. • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type. For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).
Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

c. Enter the scopes in the next screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

d. Enter the parameters for User Security in the next screen. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application grant type. Click Next when done.

Field	Description
Identity Extraction	Determines how the user credential is extracted: • Basic Authentication - HTTP basic authentication (requires no additional configuration) • Default HTML Form - Use default login form for user name and password • API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables Note: DataPower API Gateway only. Not available for DataPower Gateway (v5 compatible). • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security. • Redirect - If you select Redirect , enter the following parameters: • End Point - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL • Optional: Query parameters - Enter the query parameters. Query parameters are part of the URL come after the question mark symbol (?), usually consisting of key-value pairs separated by ampersand symbol (&). Note: To ensure the query parameters that you entered is applied to the gateway, republish your OAuth provider. • Redirect time limit - The user must verify their identity and return to the main authorization process within the specified redirect time limit. If the user exceeds this time limit, the process might fail or restart. The default redirect time limit is 300. You can adjust this duration based on your requirements. • API Gateway only Disabled - do not collect the user credential Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the `state_nonce` query parameter, otherwise the authorization fails.
Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry. For a DataPower API Gateway, you have the option to disable authentication with a user registry.
Authorization	The following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use default HTML form to authorize. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML authorization form for user security. • API Gateway only Disabled - Disable authorization.

3. Review the Summary for the native OAuth provider configuration.
4. Click Back to make changes.
5. Click Finish to save the basic configurations and to proceed to the Advanced Parameters for a native OAuth Provider.
   If you want to specify the native OAuth Provider in your Catalog, see Specifying the OAuth Providers.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

- **Configuring basic settings for a native OAuth provider**
  You can update the identification details and basic configuration settings for a native OAuth provider.
- **Configuring scopes for a native OAuth provider**
  Access tokens contain authorization for specific scopes.
- **Configuring user security for a native OAuth provider**
  Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.
- **Configuring tokens for a native OAuth provider**
  Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.
- **Configuring token management and revocation for a native OAuth provider**
  Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.
- **Configuring introspection for a native OAuth provider**
  Define an introspection path to allow the metadata for an access token to be examined.

- **Configuring metadata for a native OAuth provider**
  Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Configuring the OIDC parameters for a native OAuth provider**
  Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.
- **Editing a native OAuth provider by using the API Editor**
  You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

Configuring basic settings for a native OAuth provider

You can update the identification details and basic configuration settings for a native OAuth provider.

About this task

One of the following roles is required to configure the basic settings for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the basis settings pages for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the basic settings for an existing native OAuth provider. If you want to update the basic settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

1. To modify the identification details, click Info in the sidebar menu, then update the following fields as required:

Field	Description
Title	Enter a title for the native OAuth provider.
Name	This field is auto-populated by the system.
Description (optional)	Enter a brief description.
Base path (optional)	The base path is the URL segment of the API that is shared by all operations in the API. It does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.

2. To modify the basic configuration settings, click Configuration in the sidebar menu, then update the following fields as required:

Field	Description
Authorize Path	`/oauth2/authorize/` is the standard OAuth endpoint to login to account
Token Path	`/oauth2/token/` is the standard OAuth endpoint to exchange code for access token.
Supported grant types	• Implicit - An access token is returned immediately without an extra authorization code exchange step. • Application - Application to application. Corresponds to the OAuth grant type "Client Credentials." Does not require User Security. • Access code - An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type "Authorization Code." • Resource owner - Password - The user's username and password are exchanged directly for an access token, so can only be used by first-party clients. • API Gateway only Resource owner - JWT - A verified signed JSON Web Token is exchanged directly for an access token. Note: To use the Resource owner - JWT option, complete the following steps: • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT. • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type. For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2). Tip: If you plan to configure OpenID Connect (OIDC) for a Native OAuth provider, include at least one of the following grant types: Implicit, Access code.
Supported client types	• Confidential - Client can maintain secure credentials on a secure server • Public - Client credentials are not secure.

DataPower Gateway (v5 compatible) only Note: If the gateway type is DataPower® Gateway (v5 compatible) and, when the native OAuth provider was created, only the Application grant type was selected, you cannot add further grant types until you configure the user security settings. In particular, you must specify the user registry for authenticating application users. To configure the user security settings, complete the following steps:
   a. Click User Security in the sidebar menu, then click Edit.
   b. Update the user security settings as required; for more details, see Configuring user security for a native OAuth provider.
   c. Click Save when done.
3. Click Save when done.

Configuring scopes for a native OAuth provider

Access tokens contain authorization for specific scopes.

About this task

Client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth protected API is invoked, the gateway checks the scopes carried in the access tokens against the list of allowed scopes in the security definition for the API to determine whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The final scope permission that is granted by the access token is the result of all scope checks.

Per IETF RFC 6749, the value of the scope parameter is a list of space-delimited, case-sensitive strings. For more information, see The OAuth 2.0 Authorization Framework.

One of the following roles is required to configure scopes for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the scope settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the scope settings for an existing native OAuth provider. If you want to update the scope settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure the scopes for the access token:

1. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.

Field	Description
sample_scope_1	Scope for token
additional scopes	Scope for token

   In the Default scopes section, select the default scopes to be used if the API request doesn't contain any scopes. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.
   If the user authorization method is set to Default HTML Form in the User Security settings, all scopes specified here are added automatically to the authorization consent form.

2. Advanced scope check before token generation. This setting specifies the scope check endpoint where additional scope verification is performed in addition to the basic scopes. The advanced scope check URLs are invoked after application authentication or after owner authentication based on which URLs are configured. The scopes are included in the token and will overwrite any previous scopes.

Field	Description
Application scope check	Allow extra verification by running a scope check from an endpoint. Enter the endpoint and an optional TLS Profile to use for an application scope check.
Owner scope check	Further refine the scope with an additional check. Enter the endpoint and an optional TLS Profile to use for an owner scope check.

   For more information about scope, see Scope
3. Advanced scope check after token generation. This setting specifies an additional scope check at the API consumer level to verify compliance with the scope requirements of the API.

Field	Description
Enabled	Select the check box to enable the advanced scope check after token validation. Enter an optional default validator endpoint.
Use endpoint from API	Select the check box to use the endpoint from the API, or clear the check box to override the endpoint from the API.

   For more information about scope, see Scope
4. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider with the specified scopes can be used to secure the APIs in catalog.

Configuring user security for a native OAuth provider

Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization.

About this task

User security authenticates the user. It is required for the Implicit, Access code, and Resource owner - Password grant types. It is not used for the Application or Resource owner - JWT grant types.

One of the following roles is required to configure user security for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the user security settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the user security settings for an existing native OAuth provider. If you want to update the user security settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure the user security settings for the OAuth Provider:

1. Click User Security in the sidebar menu.
2. Specify the following parameters for User Security. Define the settings to use to extract the application users' credentials, authenticate their identities, and grant authorization. User Security is not required for the Application or Resource owner - JWT grant types. Click Next when done.

Field	Description
Identity Extraction	Determines how the user credential is extracted: • Basic Authentication - HTTP basic authentication (requires no additional configuration) • Default HTML Form - Use default login form for user name and password • API Gateway only Context variable - Specify which variable contains the user name and password. API Connect OAuth context variables as listed here API Connect context variables • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. For instructions on creating a custom form, see Creating a custom HTML login form for user security. • Redirect - If you select Redirect , enter the following parameters: ◦ End Point - Enter an endpoint to redirect to a third-party identity provider. For more information, see Authenticating and authorizing through a redirect URL ◦ Optional: Query parameters - Enter the query parameters. Query parameters are part of the URL come after the question mark (?) symbol, usually consisting of key-value pairs separated by ampersand symbol (&). Note: To ensure the query parameters that you entered is applied to the gateway, republish your OAuth provider. ◦ Redirect time limit - The user must verify their identity and return to the main authorization process within the specified redirect time limit. If the user exceeds this time limit, the process might fail or restart. The default redirect time limit is 300. You can adjust this duration based on your requirements. • API Gateway only Disabled - do not collect the user credential Note: If you use either the Default HTML Form or Redirect identity extraction methods, the response from the redirect endpoint **must** maintain the order of the query parameters before the **`state_nonce`** query parameter, otherwise the authorization fails.
Authentication	Authenticate application users with a user registry. Select an LDAP or Authentication URL user registry or create the SampleAuthURL User Registry.
Authorization	Various methods may be used to authorize application users. For a DataPower® API Gateway, the following methods for extracting the user credential are available: • Authenticated - Authorize authenticated users automatically. • Default HTML Form - Use default HTML form to authorize. If you select the Default HTML Form method, all scopes that are specified in the Scopes settings are added automatically to the authorization consent form. • Custom HTML Form - Enter the endpoint and select an optional TLS profile for a custom HTML form. • API Gateway only Disabled - Disable authorization.

3. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring tokens for a native OAuth provider

Set time to live for access tokens and refresh tokens, and a time period for maximum consent for all tokens.

About this task

Access tokens are granted to the client application to allow the application to access resources on behalf of the application user. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or more narrow scope. You can also specify how long the consent given by the combination of any number of access and refresh token remains valid.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token settings for an existing native OAuth provider. If you want to update the token settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure tokens for the native OAuth provider:

1. Click Tokens in the sidebar menu.
2. Define the settings to configure tokens.

Field	Description
Access tokens time to live	Enter the expiration time period in seconds for access tokens.
API Gateway only One time use access token	Click the check box to enable one time use for the access token. Access tokens are multiple use by default which allows them to be used for multiple requests. When one time use is enabled, the access token will be consumed after one use. The OAuth flow will need to be repeated to obtain another access token. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Refresh tokens	Click the check box to enable Refresh tokens. Set the Count to limit the number of times a refresh token can be issued. Set the Refresh Token Time to Live value to determine the time to live, or expiration time period, for each refresh token in seconds.
One time use refresh token	Clear the check box to disable one time use for the refresh tokens. Refresh tokens are one time use by default which allows them to be used one time only to generate an access token and a new refresh token. When refresh token one time use is disabled then the refresh token count is limited to one and the refresh token can be used multiple times to generate new access tokens, however, another refresh token will not be generated unless the initial OAuth flow (Authorization Code or Password) is repeated. Note: If you select this option, you must also enable token management; see one of the following topics, depending on the user interface you are using: • Configuring token management and revocation for a native OAuth provider (Cloud Manager) • Configuring token management and revocation for a native OAuth provider (API Manager)
Maximum consent	Click the check box to enable Maximum consent and enter the Maximum Consent Time to Live value in seconds. This is the time to live, or expiration time period, for all tokens, both access and refresh.
API Gateway only Token secret	Click the check box to select the Shared Secret which was configured for the gateway. If no Shared Secret was entered in the Gateway Configuration, then enter an key name and key value to use as the token secret.
API Gateway only Proof Key for Code Exchange	Proof Key for Code Exchange (PKCE) is a method to protect OAuth 2.0 public clients from an authorization code interception attack when they use Authorization Code grant requests. You can enable this extension when deploying with the DataPower® API Gateway. For more information, see RFC 7636. Select the options for your OAuth Providers: • Enable proof key for code exchange If selected, enforces PKCE when submitted in Authorization Code grant requests. • Always required If selected, requires PKCE in all Authorization Code grant requests. • Allow plain Select this check box to allow the plain challenge method in Authorization Code grant requests.

3. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

- Refresh tokens

Configuring token management and revocation for a native OAuth provider

Select whether to use a native gateway (DataPower) or third party endpoint for token revocation.

About this task

Token management enables you to prevent replay attacks by configuring token revocation. API Connect supports token revocation using a native gateway (DataPower) or a third party endpoint. For a native gateway, quota enforcement is used to manage tokens. For a third-party endpoint, a URL to an external service is used to manage tokens.

For more information, see the IETF RFC 7009 OAuth 2.0 Token Revocation.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

One of the following roles is required to configure token management and revocation for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the token management settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the token management settings for an existing native OAuth provider. If you want to update the token management settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure revocation settings for tokens:

1. Select Token Management in the sidebar menu.
2. Enable token management by selecting the check box.
3. From the Type list, select either Native or External. Native points to DataPower as the token storage location; External points to a revocation URL for token storage.
   Note: If you are using the API Manager user interface then, for the External option to be available, you must be using DataPower® API Gateway Version 10.0.1.0 or later, and the gateway service must be enabled in the Sandbox Catalog; for details on how to enable a gateway service in a Catalog, see Creating and configuring Catalogs
4. For Native, select one or both of the Resource owner revocation path and Client revocation path.
   - Resource owner revocation path - Uses the standard OAuth revocation path to allow the resource owner (end user) to revoke the application permission.
   - Client revocation path - Uses the standard OAuth revocation path to allow the client (application) to revoke a single token when the application closes.

   For more information about managing tokens with the Native DataPower Gateway, see Token management with the native DataPower Gateway.
5. For External, the settings depend on the gateway type, as follows:
   DataPower API Gateway:
   - Endpoint - the URL of the external management endpoint.
   - TLS Client Profile (optional) - the TLS client profile to secure connections.
   - Security - how to secure connections. The only supported method is basic authentication.
   - Basic authentication username (optional) - the user name for authentication.
   - Basic authentication password (optional) - the password for authentication.
   - Basic authentication request header name (optional) - the request header that contains the authentication string; if you supply both a request header name and user name/password, the request header authentication method is used.
   - Custom header pattern (optional) - the name pattern of the headers to use for sending additional information to the external management service.
   - Cache type - the cache type to control whether and how to cache positive responses. If you select Time to live, specify how long to keep responses in the cache; the default value is 900 seconds.
   - Fail on error - if selected, processing is stopped if the connection to the external management service fails.

   Note: For details of the JSON format that is required when exchanging messages with the external management service, see JSON format to exchange messages with the external management service.
   DataPower Gateway (v5 compatible):
   - Endpoint - Enter the URL to an external web server that contains information about access or refresh tokens. API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing. For more information see Token revocation.
   - TLS Client Profile - Select a TLS profile to verify the external endpoint.
6. Click Save when done.

Results

Depending on the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring introspection for a native OAuth provider

Define an introspection path to allow the metadata for an access token to be examined.

About this task

Token introspection allows an authorized holder of an access token to examine the contents of tokens using an introspection path. The access token to introspect must be obtained through the native OAuth provider. Introspection provides context for the token by allowing an authorized protected resource to query the authorization server to determine the set of metadata for a given token. The metadata includes whether or not the token is currently active, the scopes assigned to the token, and the authorization context in which the token was granted (including who authorized the token and which client it was issued to). API Connect token introspection conforms to IETF RFC 7662. See OAuth 2.0 Token Introspection.

One of the following roles is required to enable introspection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the introspection settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the introspection settings for an existing native OAuth provider. If you want to update the introspection settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to enable introspection:

1. Click Introspection in the sidebar menu.
2. Select the check box to enable Introspection. The OAuth standard path for introspection, /oauth2/introspect is automatically entered. This path will be used when another entity inspects the token contents.
3. Click Save when done.

Results

Tokens will be queried using the /oauth2/introspect path. Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring metadata for a native OAuth provider

Use Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

About this task

Configure an Authentication URL or an External URL from which custom metadata is collected for inclusion in the token. The metadata is either stored inside the access token or it is sent along with the access token to the client application. For more information about how the metadata is collected, see OAuth external URL and authentication URL.

Following are examples of metadata that can be included with the access token:

- Metadata about the authenticated resource owner
- Grant type that was used to obtain the token
- A confirmation code to be provided to the client application

One of the following roles is required to configure metadata collection for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can select the metadata settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the metadata settings for an existing native OAuth provider. If you want to update the metadata settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure metadata collection:

1. Click Metadata in the sidebar menu.
2. Select Collect metadata to enable metadata collection.
3. The Authentication URL user registry is selected by default and is required. For more information about the Authentication URL, see Authentication URL user registry.
4. Select the External URL to collect metadata from an external URL. Enter the endpoint and an option TLS Client Profile.
5. API Gateway only If required, override the default Header name token value. The value of this header, if returned in the response from the OAuth endpoint, is placed in the response payload and indicated as **`metadata`**.
6. API Gateway only If required, override the default Header name payload value. The value of this header, if returned in the response from the OAuth endpoint, is placed within the access token and indicated as **`miscinfo`**.
7. Save the OAuth Provider.
8. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring the OIDC parameters for a native OAuth provider

Open ID Connect (OIDC) provides an additional authentication protocol based on OAuth 2.0. OIDC provides user information encoded in a JSON Web Token, or JWT.

About this task

When you enable OpenID connect, a template is provided for generating ID tokens along with access tokens and the required assembly policies are automatically created. You can customize the policies to suit your needs in the API Editor. The sample key provided is for test purposes only and is used to sign the JWT token.

One of the following roles is required to configure an OIDC template for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Note: You can configure OIDC parameters only if the selected grant types for the native OAuth provider include at least one of the Implicit or Access code grant types; see Configuring basic settings for a native OAuth provider.
You can select the OIDC settings page for a native OAuth provider immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the OIDC settings for an existing native OAuth provider. If you want to update the OIDC settings for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to configure an OIDC template:

1. Click OpenID Connect.
2. Select Enable OIDC and then enter the following parameters as appropriate:

Field	Description
Support hybrid response types	Optional. Select the response types for the OpenID Connect hybrid flow to be supported by this OAuth provider.
Auto Generate OIDC API Assembly	Optional. Select this option to generate the full OIDC assembly. Leave this option unselected to simply enable OIDC support in the OAuth provider, and allow developers to implement their own assemblies.
ID token issuer	Descriptive text to indicate the source of the key.
ID token signing crypto object	The cryptographic object to use to sign the token.
ID token signing key	The JSON Web Key (JWK) to be used to sign the ID token.
ID token signing key identifier	The key ID used for signing the token.
ID token signing algorithm	The algorithm used to sign the token.
OpenIDConnect Discovery path	A URL that is exposed by the provider and allows a client to send a request for information about the provider's publicly visible configuration.

3. Click Save when done. You can edit the policies by using the API Editor.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Editing a native OAuth provider by using the API Editor

You can edit the source and assembly policies for the Native OAuth Provider using the API editor.

About this task

If you have configured an OIDC template, you can customize it in API Editor. In the API Editor, the Source tab allows you to edit the code for the configuration using a text editor. The API Assemble tab provides a graphical drag-and-drop editor (identical to the one in API Manager) that allows you to add additional elements to the assembly for the OAuth Provider.

Note: Take care when modifying the code directly on the Source tab of the API Editor because validation is limited. For example:

- If you change the name of auto generated assembly actions in the source code, the assembly will be prevented from updating dynamically when the OAuth provider settings are modified.
- You must ensure that the OAuth provider name matches the value specified in the **`oauth-provider-settings-ref`** field in each OAuth assembly action.

One of the following roles is required to configure tokens for a native OAuth Provider:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

You can modify the native OAuth provider configuration by selecting the API Editor page immediately on completion of the creation operation detailed in Configuring a native OAuth provider, or you can update the configuration for an existing native OAuth provider. If you want to update the configuration for an existing native OAuth provider, complete the following steps before following the procedure described in this topic:

1. Click Resources > OAuth Providers.
2. Select the required native OAuth provider.

Procedure

Perform the following steps to edit the OAuth configuration:

1. Click API Editor.
2. In the Source tab, view and edit the policies to customize the behavior for the OAuth provider.
3. In the API Assemble tab, use the drag and drop editor to add additional policies to the OIDC behavior.
   Note: If you add a policy that references a TLS profile, an **invoke** policy for example, then when you publish an API that uses this OAuth provider, you must ensure that the TLS profile is enabled for the Catalog to which you publish the API. For details on how to enable a TLS profile in a Catalog, see Creating and configuring Catalogs.
4. Click Save when done.

Results

Depending upon the visibility setting, the OAuth Provider can be used to secure the APIs in catalog.

Configuring a third-party OAuth provider

Enter the secure endpoints to provide OAuth authentication from a third party.

About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Procedure

Complete the following steps to configure a third party OAuth provider:

1. In the Cloud Manager, click Resources.
2. Select OAuth Providers > Add > Third party OAuth Provider.
   a. Complete the following parameters for the first screen and click Next.

Field	Description
Title	Enter a descriptive title for the gateway service. This title will be displayed on the screen.
Name	This field is auto-populated by the system and used as the internal field name.
Supported grant types	Select from the following options: • Implicit: An access token is returned immediately without an extra authorization code exchange step. • Application: Application to application. Corresponds to the OAuth grant type Client Credentials. Does not require User Security. • Access code: An authorization code is extracted from a URL and exchanged for an access code. Corresponds to the OAuth grant type Authorization Code. • Resource owner - Password: The user's username and password are exchanged directly for an access token, so can only be used by first-party clients. • API Gateway only Resource owner - JWT: a JSON Web Token (JWT) Bearer Token is used as a means for requesting an OAuth 2.0 access token, and for client authentication, as defined by the JSON Web Token (JWT) Profile for OAuth 2.0 Client Authentication and Authorization Grants. Note: To use the Resource owner - JWT option, complete the following steps: • In the Supported grant types field, select both Resource owner - Password and Resource owner - JWT. • Edit the API definition and add a security scheme that specifies oauth2 as the security definition type and select Resource owner - Password as the flow type. For instructions on defining an OAuth2 security scheme for an API, see Defining OAuth2 security scheme components (OpenAPI 3) or Defining OAuth2 security schemes (OpenAPI 2).
Gateway type	Select the gateway type, either DataPower® Gateway (v5 compatible) or DataPower API Gateway. For information about types of gateways, see API Connect gateway types. OAuth Providers apply to one gateway type.

   b. Specify configuration settings for the endpoints, and then click Next.

Field	Description

Field	Description
Authorization URL	An authorization URL where the resource owner grants authorization to the client application to access a protected resource. Example: `https://example.com/oauth2/authorize`
Token URL	A token request URL where the client application exchanges an authorization grant for an access token. Example: `https://example.com/oauth2/token`
Introspect URL	The introspection URL is where the API gateway validates the access tokens that are issued by the third party provider. Example: `https://example.com/oauth2/introspect` For more information on integrating third party OAuth providers for introspection, see OAuth introspection for third-party OAuth providers.
API Gateway only Introspect cache type	The cache type determines how long responses from the third party provider are cached, if at all. Select one of the following options: • No cache (default): Responses are not cached. • Protocol: Defined by the `cache-control` header in the provider response. • Time to live: Defined by the provider.
API Gateway only Cache Time to Live	The length of time, in seconds, for which provider responses are cached, if the Introspect cache type is set to Time to live. The default value is 900.
TLS Profile (optional)	Select an optional TLS profile for communicating with the third party provider.
Security	Default is Basic Authentication.
Basic authentication request header name	The `x-introspect-basic-authorization-header` is available to provide a user-configured HTTP Basic authorization header.
API Gateway only Basic authentication username (optional)	The default user name for HTTP Basic authentication.
API Gateway only Basic authentication password (optional)	The default password for HTTP Basic authentication.
API Gateway only Token validation	Specifies the method used to determine the success of the introspection request that is sent to the third party service to validate the provided token. Select one of the following options: • Connected: The query is successful if the status return code is `200`. • Active (default): The query is successful if the status return code is `200` and the response JSON body includes the property `active: true`.
API Gateway only Custom header pattern (optional)	A regular expression for request headers that are to be passed to the third-party provider; for example, `x-Introspect-*`.
API Gateway only Authorization header pass through	Select this check box if you want to retain the `Authorization` header for a bearer token. The default behavior is to remove this header.

c. Enter the scopes in the third screen. A scope becomes an option in the request and response for an access token. Click Add to add additional fields for scopes. Click Next when done.

Field	Description
sample_scope_1	Scope for token
sample_scope_2	Scope for token
additional scopes	Scope for token

d. Review the settings on the Summary panel.

3. Click Save and Edit to complete the configuration.
If you want to specify the third party OAuth Provider in your Catalog, see Specifying the OAuth Providers.

- **Configuring scopes for a third-party OAuth provider**
Access tokens contain authorization for specific scopes.

Configuring scopes for a third-party OAuth provider

Access tokens contain authorization for specific scopes.

About this task

Client applications can request only the scopes or a subset of the scopes that you define here. The scopes are included in the access tokens that are generated from the provider. When an OAuth-protected API is called, the gateway checks the access token's scopes against the allowed scopes in the API's security definition to decide whether to grant access.

In addition, you can enforce advanced scope checks. The advanced scope check URLs are invoked after application authentication or after user authentication based on which URLs are configured. The access token grants the final scope permission based on the results of all scope checks.

One of the following roles is required to configure scopes for a third-party OAuth Provider:

- Administrator
- Owner
- Topology Administrator

- Custom role with the `Settings:Manage` permissions

Procedure

When you create a third-party OAuth provider, you can add scopes immediately. For more information, see Configuring a third-party OAuth provider or you can update the scope settings for an existing third-party OAuth provider. The Advanced scope check after token generation option is not available during creating a third-party OAuth provider. To edit Scopes and enable the Advanced scope check after token generation settings for an existing third-party OAuth provider, complete the following steps:

1. Click Resources > OAuth Providers.
2. Select the third-party OAuth provider that you want to edit the scope.
3. Click Scopes in the sidebar menu. The currently configured scopes are listed. Review and update the scopes as required.
4. To add new Scopes, complete the following steps:
   - Click Add.
   - Enter the Name and Description for new scope.
   - Click Save.
   - To delete existing scopes, click Delete.
5. To Implement an extra scope check at the API consumer level to ensure the compliance with the API's scope requirements, complete the following steps:
   - Select the Enabled checkbox to enable the advanced scope check after token validation.
   - Enter the Default validator endpoint.
   - **Optional:** Select the TLS client profile to use for an owner scope check. For more information about TLS client profile, See TLS profiles overview.
   - Select the Use endpoint from API checkbox to use the endpoint from the API. If you selected Use endpoint from API, the Default validator endpoint is optional.
   - If you want to enable basic authentication, select Enable security checkbox and fill the following parameters:

Table 1.

Field	Description
Mode	Select Basic authentication.
Optional: Basic authentication request header name	A default header name is provided, which you can modify to meet your specific requirements.
Optional: Basic authentication username and password	Enter the `username` and `password`.
Optional: Request headers and Response context variables	Enter `Request headers` and `Response context variables`. Make sure that it is in **`Perl Compatible Regular Expressions`** format. For more information about PCRE format, see PCRE.

   - Click Save when done. For more information about scope, see Scope.

Results

Depending upon the visibility setting, the OAuth Provider with the specified scopes can be used to secure the APIs in catalog.

Setting the visibility for OAuth providers

The visibility setting determines which provider organizations can use an OAuth provider to secure APIs.

About this task

One of the following roles is required to configure OAuth Providers:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings:Manage` permissions

Procedure

Follow these steps to set the visibility for the OAuth providers in your on-premises cloud:

1. In the Cloud Manager, click Resources.
2. Select OAuth Providers.
3. Choose Edit visibility from the actions menu next to the name of the OAuth provider that requires a visibility setting.
4. Select the visibility setting for the OAuth provider. The options are:
   - Private - the OAuth provider is not visible and cannot be used by any provider organization. It is accessible only to the admin organization in Cloud Manager.
   - Public - the OAuth provider is visible and can be used by all provider organizations
   - Custom - the OAuth provider is visible only to the provider organizations that you designate
5. For Custom visibility, select the provider organizations that you want to have access to the OAuth provider.
6. Click Save to complete the operation.

Results

For Private, the OAuth provider is not visible and cannot be used by any provider organizations. For Public, the OAuth provider is visible and can be used by all provider organizations. For Custom, the OAuth provider is visible only to the provider organizations designated by you.

OAuth concepts for API Connect

OAuth is a token-based authorization protocol that allows third-party websites or applications to access user data without requiring the user to share personal information.

Note: In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

- **OAuth user scenario**
  Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.
- **OAuth introspection for third-party OAuth providers**
  OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by API Connect. IBM API Connect can use this feature along with the mentioned provider to protect access to the API.
- **OAuth external URL and authentication URL**
  You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.
- **Scope**
  Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.
- **Tokens**
  Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.
- **Authentication URL user registry**
  You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.
- **Custom forms for user security**
  You can create custom forms for the authorization and identity extraction phase of OAuth.
- **Securing an API with a JSON Web Token**
  There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM API Connect.
- **Troubleshooting OAuth**
  You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

OAuth user scenario

Potential users of OAuth with IBM® API Connect have a number of methods to secure their API. The following scenario provides an overview of the available options.

Scenario overview

In this scenario, Alice is a user of an application. Alice can grant permission for an application to access specific information about Alice in a third-party system that is using OAuth. Depending on the type of OAuth that is supported by the target service, Alice does not enter her user name and password into the application. Instead, the application receives an access token that represents her credentials (user name and password). The application can now access the information about Alice in the target system.

For example, Alice maintains a list of books that she reads on a service that is provided by mybooks.com. Following the purchase of a smartphone, Alice installs an application on her new phone to display the book details. The phone application wants to call an API provided by mybooks.com, which can access the information. The mybooks.com API is secured by using the OAuth protocol.

To access the book details, the application must complete a two-step process:

1. The application must first obtain permission from Alice.
2. The application then uses that permission to call the target service and obtain the list of books.

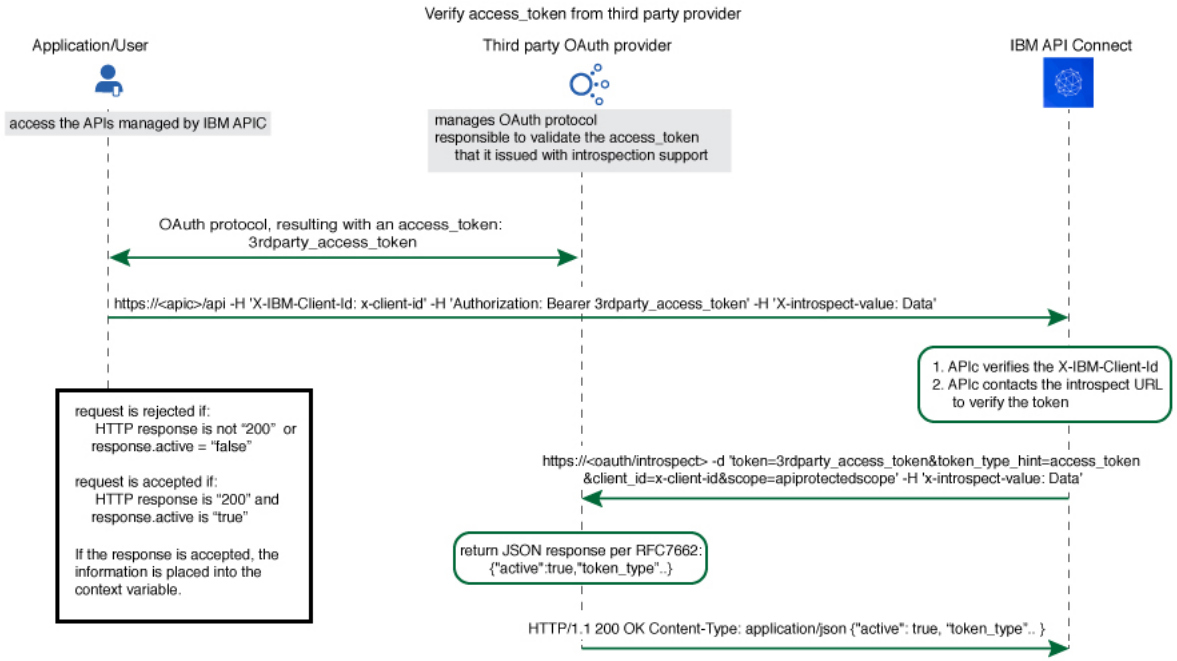
In the first step, the application typically directs Alice to the provider of the target service, mybooks.com. Alice provides her user name and password, and gives permission for the application to access her information. It is important that Alice trusts that she is providing her credentials to the provider of the target service and not to an untrusted proxy application. For example, by checking that the security certificate of the website where Alice enters her credentials matches what Alice expects from the provider of the target service.

The result of this step is the access token that the application can use to call the API. The application then generates the appropriately formatted OAuth request. For example, the Authorization header, or HTTP query parameters, which includes the access token, consumer key, and signature method that are required by OAuth. This OAuth request is used to invoke the API proxy operation.

Scenario within API Connect

No changes to the definition of your API operation are required to support this scenario.

1. Alice grants permission for the application to access her information *before* the invocation of the API.
2. When the application provides the Authorization header, or query parameters, containing the OAuth details about the call to the operation endpoint, the header is automatically passed through to the target service without any additional configuration.



OAuth introspection for third-party OAuth providers

OAuth token validation can be offloaded to the third-party Open Authorization (OAuth)/Open ID Connect (OIDC) provider by using the Introspection URL. Clients can use a third-party OAuth or OIDC provider to obtain a token that is protected by API Connect. IBM® API Connect can use this feature along with the mentioned provider to protect access to the API.

You can use API Connect to protect an API that is secured by using the third-party OAuth access token in accordance with Introspection specification as defined in RFC 7662. In addition to the specification, the **`x-Introspect-`** header is provided to pass other content to the third party as you require.

Authentication information can be carried in the request by configuring a basic authentication request header.

The following sequence diagram depicts the overall flow of request and response. The purpose of this diagram is only to provide a general visualization of the nature of the flow; for the precise details, refer to the explanatory information after the diagram.

The Introspect URL is configured in the Third Party OAuth provider configuration. See Configuring a third-party OAuth provider.

When an API is protected by a third-party OAuth provider, API Connect will extract the bearer token and issue an HTTP POST request to the endpoint specified in the Introspect URL field.

The GET request is protected by API Connect with this feature.

You can use a header prefix to pass information to the third-party provider. The header prefix can include a regular expression and specifies the name pattern of the headers to use for sending additional information, such as **`x-introspect-*`**.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
Authorization: Bearer tGzv3JOkF0XG5Qx2TlKWIA
x-IBM-Client-Id: xxx-xxx
```

However, if you want to use a different header prefix, specify the required value in the Custom header pattern field in the third party OAuth provider configuration. For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider. The Custom header pattern feature is available only with the DataPower® API Gateway, if you are using the DataPower Gateway (v5 compatible) the header prefix must be **`x-Introspect-`**.

API Connect will issue this POST request to the introspection endpoint specified in **`x-tokenIntrospect`**, as illustrated in the code sample:

```
POST /oauth/introspectURL HTTP/1.1
Host: apiconnect.ibm.com
Content-Type: application/x-www-form-urlencoded
x-Introspect-type: dog
x-Introspect-name: simon
x-custom-apic: petstore123
token_type_hint=access_token&token=tGzv3JOkF0XG5Qx2TlKWIA
```

The third party OAuth/OIDC provider will respond with `HTTP 200` indicating the request was successful and that payload contains the token information. API Connect honors the active claim as defined in the RFC specification.

If the value of the active claim is `true`, the token is treated as valid.

```
HTTP/1.1 200 OK
 Content-Type: application/json;charset=UTF-8
 Cache-Control: no-store
 Pragma: no-cache

 { "active":true,
    "token_type":"bearer",
    "client_id":"xxx-xxx",
    "username":"John Smith",
    ...
 }
```

If the value of the active claim is `false`, the token is treated as invalid.

```
 HTTP/1.1 200 OK
 Content-Type: application/json;charset=UTF-8
 Cache-Control: no-store
 Pragma: no-cache

 {
   "active":false
 }
```

A response code other than **`HTTP 200`** indicates failure to process the request.

When the OAuth token is valid and active, context variables are populated with information from the introspect JSON response. For more information, see API Connect context variables.

When contacting the introspection endpoint, API Connect uses **`client_id`**/**`appId`** and **`client_secret`**/**`appSecret`** to construct the HTTP Basic authorization header.

By default, if **`x-introspect-basic-authorization-header`** exists in the request, the value is used for the HTTP Basic authentication header when the introspection endpoint is contacted. API Connect verifies that the HTTP Basic authentication header value is Base64 encoded before it is sent, and encodes it if necessary as shown in the following example. If the header is already encoded, it is sent without modification.

```
GET /petstore/pet/123 HTTP/1.1
Host: apiconnect.com
x-introspect-basic-authorization-header: user:password
```

API Connect issues the following:

```
POST ..
Authorization: Basic M3JkLXBhcnR5LWNsaWVudF9pZDozcmQtcGFydHlfY2xpZW50X3NlY3JldA==token_type_hint=access_token&token= ..
```

If you are using the DataPower API Gateway, you can specify your own value for the HTTP Basic authentication header by providing the required value in the Basic authentication request header name field in the third party OAuth provider configuration. The following rules determine what authentication data is passed to the introspection endpoint:

- If there is a basic authentication header in the request, the specified credentials are used. The value must be either a string in the format ***`user:password`***, or the Base64 encoded equivalent; API Connect will Base64 encode the value if necessary before sending the request to the introspection endpoint.
- If there is no basic authentication header in the request but there are values specified in the Basic authentication username and Basic authentication password fields in the third party OAuth provider configuration, those values are used.
- If there is no basic authentication header in the request, and user name and password details are not supplied in the third party OAuth provider configuration, but **`client_id`** and **`client_secret`** values are supplied in the body of the request, these are used.
- Otherwise, an error is returned.

For third-party OAuth provider configuration details, see Configuring a third-party OAuth provider.
If either, or both, of scope and **`scope validate url`** are configured, and if the response is an active token with a scope claim from the third-party OAuth Provider introspection endpoint, API Connect will further enforce the scope validation in the following order:

1. If **`scope`** is configured for the OAuth API protection, verify the third-party scope against the scope that is configured.
2. If **`scope validation url`** is configured, verify the third-party scope against the scope validation URL.
3. If the third-party OAuth provider introspection endpoint does not return a scope, the Gateway will not check the scope defined in the security definition of the API where the third-party OAuth provider resource is used. For details on configuring an OAuth security definition in an API, see Creating an OAuth security definition.

For more information, see Scope.
DataPower Gateway (v5 compatible) only By default the API Connect client ID and scope are sent to the third party OAuth provider. You can suppress this behavior in either of the following ways:

- Supply a **`suppress-parameters`** header as follows:

  `suppress-parameters: client_id`

  `suppress-parameters: scope`

  or

  `suppress-parameters: client_id scope`

  depending on which parameters you want to suppress.
- Define an API property called **`suppress-parameters`** in the API definition itself, with one of the following string values:

  `client_id`

  `scope`

  or

  `client_id scope`

depending on which parameters you want to suppress. For information on how to define API properties, see Setting API properties.

OAuth external URL and authentication URL

You can use the Authentication URL or External URL parameters to request user-defined content from a remote server and include it in the access token or in the response payload that contains the access token.

Including custom metadata in a token

In many scenarios, custom metadata needs to be included during the access token generation process. The metadata is either stored inside the access token or it is sent along with the access token to the client application. The client application can then send that access token, or the metadata in the payload, in a subsequent request to IBM® API Connect where the metadata is retrieved, validated, or sent to the downstream systems as required.

Examples include, but are not limited to:

- When resource owners are authenticated, metadata about the authenticated resource owner needs to be stored within the access token.
- The grant type that was used to obtain the token is another example of metadata stored within the access token.
- A confirmation code that needs to be sent to the client application along with access token is stored as metadata within the access token.

Configuring External URL or Authentication URL in API Connect to obtain metadata

Metadata can be set by using either or both of the following URLs:

- External URL - When you call the External URL, an HTTP GET request is sent and API Connect expects an HTTP 200 OK along with an optional set of the specified response headers.
- Authentication URL - When you call the Authentication URL, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.
  See: Authentication URL.

The External URL endpoint is entered in the Metadata section when you configure an OAuth Provider in the Cloud Manager or API Manager UI.

Use the following HTTP headers in the response, depending on the type of gateway you are using:

- DataPower® API Gateway:

  `X-API-OAUTH-METADATA-FOR-PAYLOAD`

  `X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`

  Note: These are the default header names for the DataPower API Gateway but you can override them; see Configuring metadata for a native OAuth provider.
- DataPower Gateway (v5 compatible):

  `API-OAUTH-METADATA-FOR-PAYLOAD`

  `API-OAUTH-METADATA-FOR-ACCESSTOKEN`

The response header value from **`X-API-OAUTH-METADATA-FOR-PAYLOAD`** or **`API-OAUTH-METADATA-FOR-PAYLOAD`** is placed in the response payload and indicated as **`metadata`**.

The response header value from **`X-API-OAUTH-METADATA-FOR-ACCESSTOKEN`** or **`API-OAUTH-METADATA-FOR-ACCESSTOKEN`** is placed within the access token and indicated as **`miscinfo`**.

The two metadata response headers are case insensitive and you must escape any special characters in the string value content.

An example response payload that contains metadata along with the access token:

```
{
"token_type":  "bearer",
"access_token":  "AAEkNzhjDHYyyYy...cL0Mv6ctl37w7ZU",
"metadata":  "m:metadata-for-payload_content"
"expires_in":  3600,
"scope":  "read",
"refresh_token":  "AAEnj5SynCMybF...oEZ6JjxYax_HdNg",
}
```

This example output from the token introspection endpoint shows the contents of the access token with **`"miscinfo"`** containing the metadata information.

```
{
"active":  true,
"token_type":  "bearer",
"client_id":  "78c2f10f-799a-4e1f-8e0a-098634997a35",
"username":  "Fred Smith",
"sub":  "fred",
"exp":  1479850049,
"expstr":  "2016-11-22T21:27:29Z",
"iat":  1479846449,
"nbf":  1479846449,
"nbfstr":  2016-11-22T20:27:29Z",
"scope":  "read",
"miscinfo":  "m:metadata-for-accesstoken_content",
"client_name":  "MobileApp"
}
```

Input to the External URL

The following request headers are sent to the External URL.
Note: Any existing metadata values that were previously sent from the Authentication URL are also sent in the two request headers **x-existing-metadata-for-payload** and **x-existing-metadata-for-access-token**. The Metadata URL can make use of this information to create a new set of metadata values.
The two request headers that are sent to the Metadata URL are displayed in bold text.

```
X-existing-metadata-for-payload     payload-from-auth-url
X-existing-metadata-for-access-token     token-from-auth-url
X-URI-in     /org/env/miscinfo/oauth2/token (the URL that was sent to APIConnect for this particular token request)
X-METHOD-in     POST
X-POST-Body-in     client_id=client_id&grant_type=password&scope=read&username=name&password=password
X-X-Client-IP     IP_address
X-X-Global-Transaction-ID     ID_number
...
```

Note: If you are using the DataPower API Gateway rather than the DataPower Gateway (v5 compatible), the **X-POST-Body-in** header is not supported.

Retrieving Metadata in API Connect

As described in the previous example scenarios, the metadata can be retrieved from the access token in the Application API and sent to the downstream systems. Retrieval can be done in the API assembly, which is secured to accept tokens in the security definitions.

In the resource API that accepts an access token, the **miscinfo** field can be accessed in the Assembly with the **oauth.miscinfo** context variable, as in the example.

```
apim.setvariable('message.body',apim.getvariable('oauth.miscinfo'));
```

You can also use token introspection to look at the contents of the access token.

Refresh tokens and metadata

The Authentication URL (if configured for authentication) is invoked first, during authentication of the resource owner. The External URL is invoked as the last step, just before the generation of the access token. The only exception is when access tokens are generated from a refresh token. In cases where refresh tokens are used to generate new access tokens, the External URL is not invoked. The metadata from the refresh token is retained and then copied into the newly generated access token.

Identifying the source of the metadata

The metadata is prefixed with keywords to indicate whether it originated from the External URL or the Authentication URL.

- Metadata from the External URL is prefixed with **m:**
- Metadata from the Authentication URL is prefixed with **a:**

Note: When revocation is enabled, some internal details are also stored in the **miscinfo** field, in brackets within the access token as shown in the following example:

```
"miscinfo": "[tlsprofile@https://api-revoke-url:443/server/revocation-url]m:metadata-for-accesstoken_content"
```

Maximum size of the metadata

Metadata for the access token cannot exceed 512 bytes.

Metadata for the payload does not have a specific size restriction, except for when you use the Authorization code grant type. These restrictions are described in following sections.

Characters are not allowed in metadata in certain scenarios

When you use the Authorization code grant type, or when a consent form is used for implicit grant type, there is a temporary state or code where the metadata from the authentication URL is stored. API Connect internally uses two prefixes - **!ma** and **!mp** to differentiate between payload and token metadata received from the Authentication URL and store them internally in the temporary state/code. Hence these specific character sequences - **!ma** and **!mp** should not be used as the metadata itself.

Grant types and metadata

The OAuth grant types described in the following sections include **authorization code (access code)**, **implicit**, and **client credentials (application)**.

Authorization code grant type

- When metadata is included from an Authentication URL for an Authorization code grant type, as it is a three legged flow, both the content and the payload are stored within the **dp-state** and carried on to the authorization code and to the access token. Note that around 10 characters are used internally to differentiate between the metadata for payload and metadata for the access token when stored in the **dp-state**. In addition, if revocation is enabled, that will also be part of the token metadata. Hence the combined size of the token metadata, the payload metadata (including the 10 characters of internal data), and internal revocation details, cannot exceed 512 bytes in total.

  If the overall size of the metadata exceeds 512 bytes, then the access token generation succeeds, but the metadata fields contain an error message of "`metadata too large`" as shown in the example.

  ```
  "metadata":"m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-payload]"
  "miscinfo":"[r:gateway]m:error: metadata too large for AZ code grant type[Authorization Code-metadata-url-token]"
  ```

This size restriction can be overcome when the metadata is sent from the Metadata URL and not from the Authentication URL, because the metadata is not stored in **dp-state** or in the authorization code.

Example of the **authorization code (access code)** grant type:

```
 $ curl -k -d
"grant_type=authorization_code&code=$mycode&client_id=$myid&scope=scope_introspect&redirect_uri="
https://9.70.153.90/fei/sb/introspectp1/oauth2/token
{ "token_type":"bearer",
"access_token":"AAEkOThlZDhhNjYtYTQ1ZS00YTMzLWE0N2QtZmE2OGZkMzQ0NzQ20ZN5Tl_TqYFeIfB7BFf6HFgibEoOjWXXEA84oFsWuE4NY-
RRZVdnGSaXAIYJz7s5vczfk5EV-BIb_6P_lYKm3ahrfhR5kI3sPO0uADEoseIP5-O9anUpEM5yhsayXvZbJ_6VDYz-hyXSJHTNqVj-
PHBialoRkBD5qca6kO0fV2M", "metadata":"a:[Authorization Code-Test-auth-url-payload]", "expires_in":3600,
"scope":"scope_introspect", "refresh_token":"AAFAg1EVMbwicr_L0fTZ4q6HZ-
RcQygniXFC9zbSKO4wd3hcniC4KQX21X0fL2c8cnmzCZgws8xxLzNyfjQhUJNGl5C1GbIe3dwhXJdiWA0Go-
dduhVtCbG26sJRRXyYrMeRxWnJsylBETPI8HQEN4a_D7fmxKcTVRZBvq86byg95qe1ZKyERi0Lhxdd_O4Nvss" }

$ curl -k -H "X-IBM-Client-Id: $myid" -H "X-IBM-Client-Secret: $mysecret" -d
"token_type_hint=access_token&token=$mytoken" https://9.70.153.90/fei/sb/introspectp1/oauth2/introspect
{ "active":true, "token_type":"bearer", "client_id":"98ed8a66-a45e-4a33-a47d-fa68fd344746", "username":"anyuser",
"sub":"anyuser", "exp":1484766368, "expstr":"2017-01-18T19:06:08Z", "iat":1484762768, "nbf":1484762768,

Test-auth-url-token]", "client_name":"oauth_app" }
```

Client credentials grant type

Authentication URL will not be invoked when using client credentials grant type, as there is no resource owner. The metadata from Authentication URL is not available for this grant type. However, content returned from Metadata URL will be included as metadata.

Behavior when retrieving metadata with both an External URL and an Authentication URL

If an External URL is configured and a connection to the external server is successful, the response headers overwrite any existing metadata obtained from the Authentication URL to become the final value. Therefore, you must carefully examine the incoming request headers and create appropriate response headers from the External URL.

If an External URL is configured, but the connection to the External URL fails, then a failure message of "`error on metadata url`" is written for metadata in both the payload and the access token.

If an External URL is configured and the connection is successful, but the remote server does not send any of the specified HTTP response headers, a blank value is written for metadata in both the payload and the access token.
Attention: An External URL overwrites existing values from Authentication URL. This includes blank values.
If no External URL is configured, the metadata that is obtained from the Authorization URL is retained as the final value.

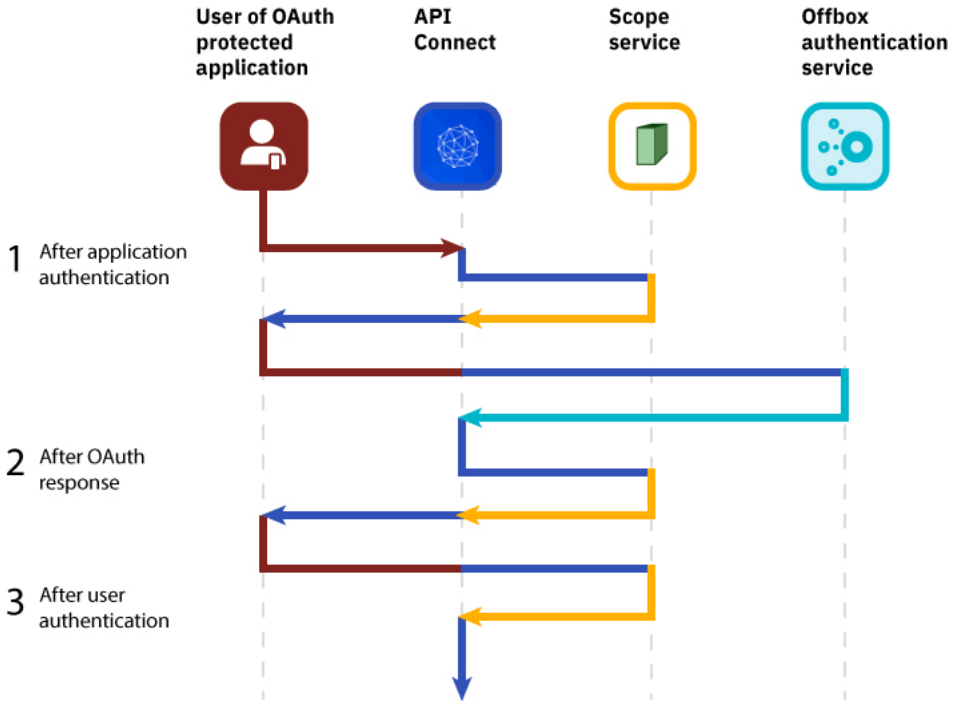
Scope

Per IETF RFC 6749, the value of the scope parameter is expressed as a list of space-delimited, case-sensitive strings.

In IBM® API Connect, scopes have no inherent meaning. Instead, scopes are defined in the OAuth Provider so that an application can request an access token that is valid for one or more of the scopes. In the secured API, scopes are listed as requirements for an access token to be considered valid. All scopes that are listed by the security definition for the API must be granted by the access token.
Note:

- An OAuth Provider must have at least one scope.
- An OAuth token will not be granted unless a default scope is configured at the provider, or one or more predefined scopes are included in the grant request.
- If no default scope is defined, and the request does not contain a scope, an invalid scope error is returned for the request.

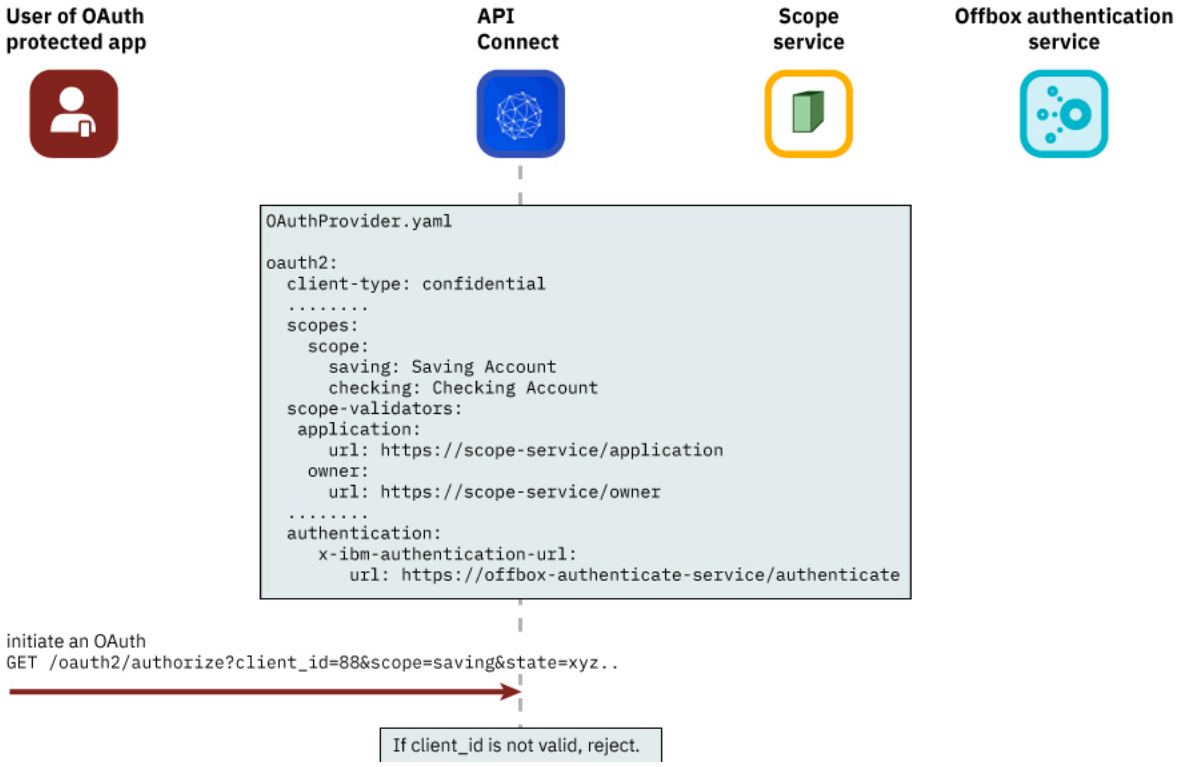
OAuth provider



To provide more refined support for the OAuth scope handling, API Connect allows the Authentication URL user registry extension to modify the scope value.

When you define an OAuth provider, the Advanced scope check extensions provide the flexibility to check and override allowed scopes. The optional extensions are Application scope check and Owner scope check.

The scope that is eventually received by the application is determined by the interactions that are described in the three following paragraphs. Scope processing follows the sequence of items 1, 2, and 3 in the following list, offering three opportunities to override the scope value. Figure 1 provides an overview of the process.



1. After the application successfully authenticates, and if OAuth Native provider > Advanced scope check > Application scope check is configured, API Connect makes a call to allow extra verification and uses the contents of **`x-selected-scope`** to override the scope value that was initially requested by the application. When Application scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.
2. If OAuth Native provider > User Security > Authentication is configured to authenticate application users using an Authentication URL, then API Connect makes a call, as documented in Authentication URL user registry. When the response code is `HTTP 200`, and the response header **`x-selected-scope`** is present, the value that is configured in **`x-selected-scope`** is used as the new scope value, overriding both what the application already requested and what was provided in the Application scope check described in paragraph 1. In the response header, **`x-selected-scope`** is an optional element.
3. After the user successfully authenticates, and if OAuth Native provider > Advanced scope check > Owner scope check is enabled and configured with a valid URL, API Connect makes a call to allow the content of **`x-selected-scope`** to refine the scope value. When Owner scope check is enabled, the HTTP response header **`x-selected-scope`** must be present, or the call fails.

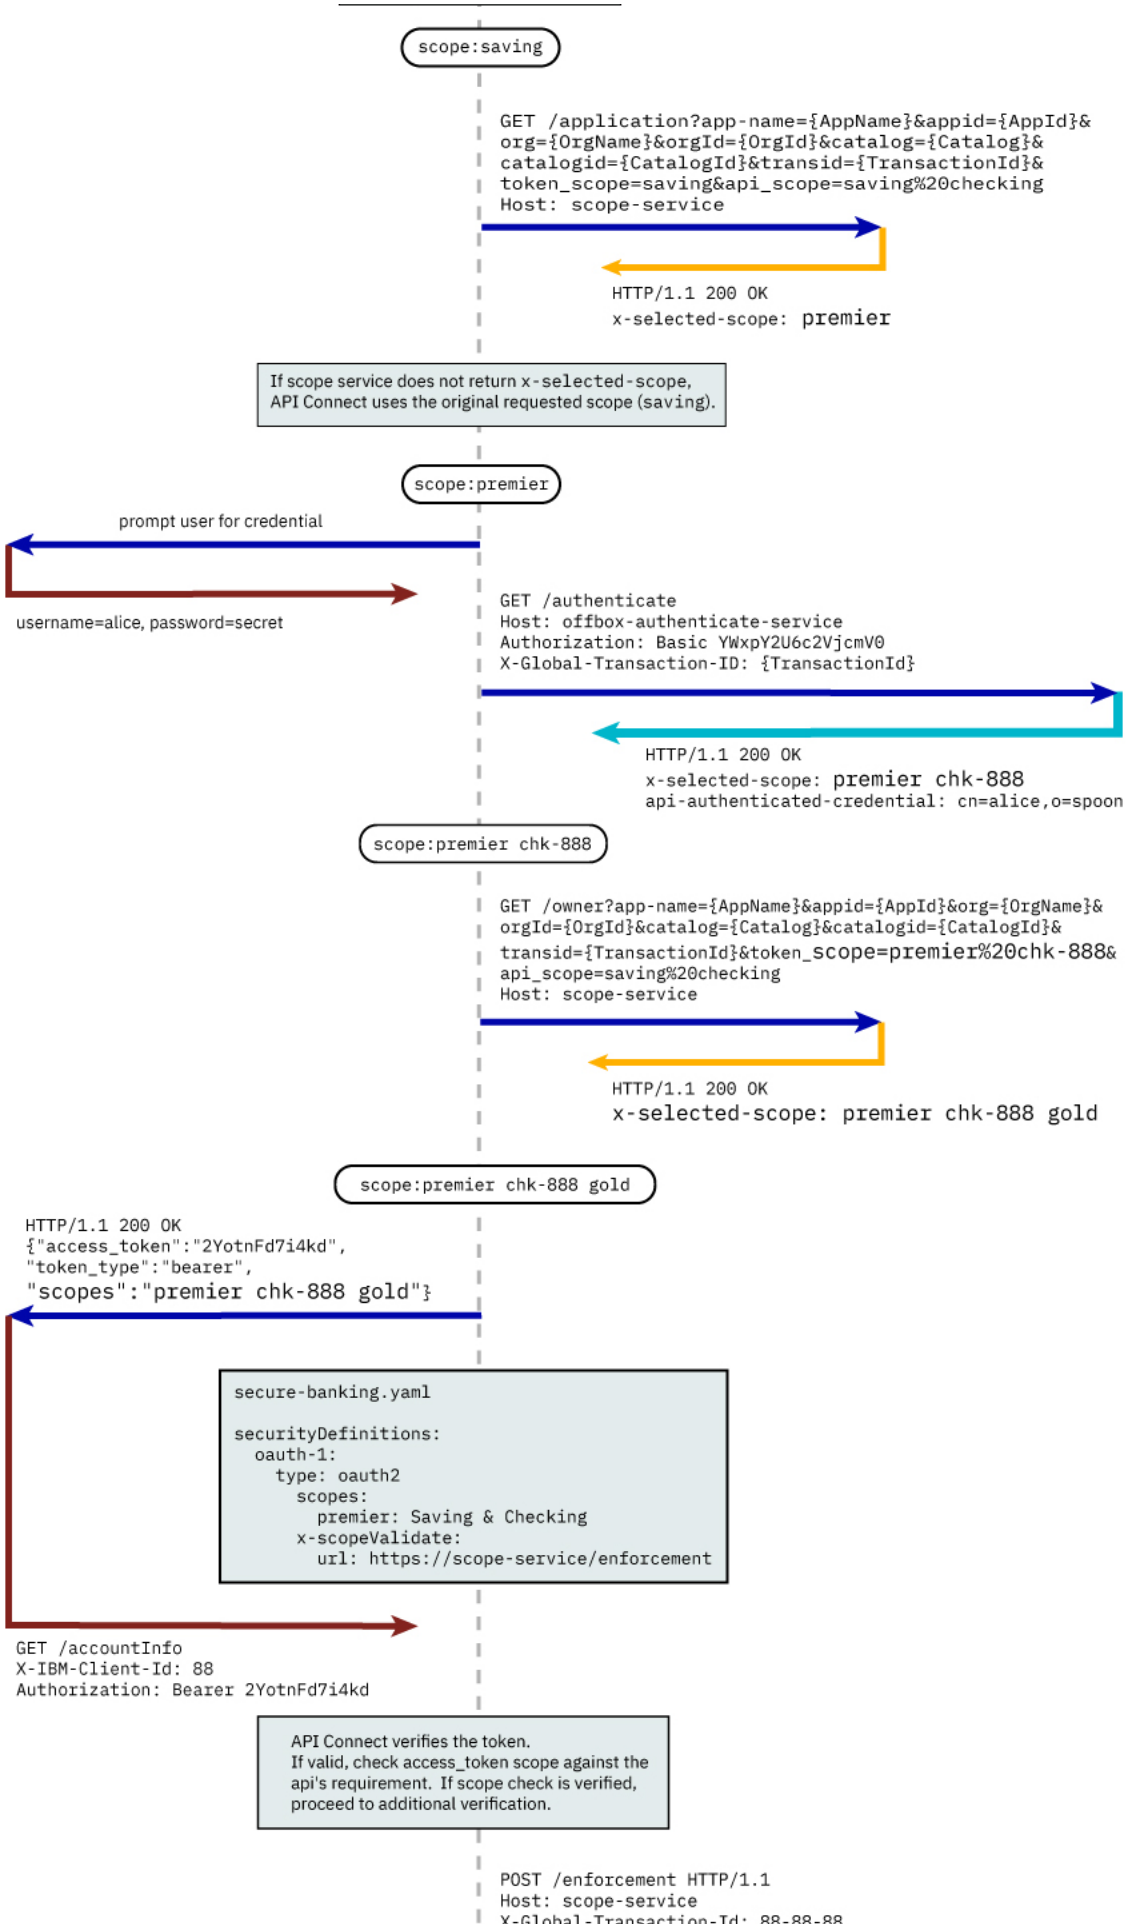


Figure 1. OAuth advanced scope overview

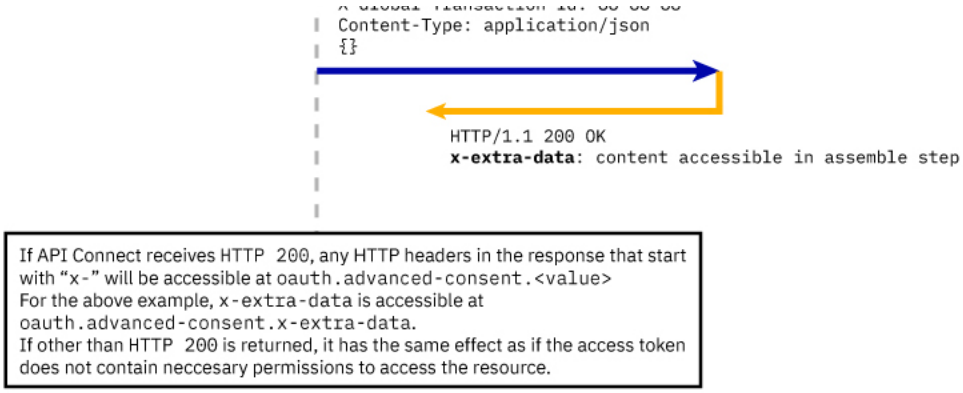

The final scope permission that is granted by the access token is the result of the flow described in items 1, 2, and 3. Figure 2 shows a more detailed view of the transaction flow with examples that show when **`x-selected-scope`** provides a new scope value.

Figure 2. OAuth advanced scope detail

scope:saving
GET /application?app-name={AppName}&appid={AppId}&
org={OrgName}&orgId={OrgId}&catalog={Catalog}&
catalogid={CatalogId}&transid={TransactionId}&
token_scope=saving&api_scope=saving%20checking
Host: scope-service
HTTP/1.1 200 OK
x-selected-scope: premier
If scope service does not return x-selected-scope,
API Connect uses the original requested scope (saving).
scope:premier
prompt user for credential
username=alice, password=secret
GET /authenticate
Host: offbox-authenticate-service

"scopes":"premier chk-888 gold"}
secure-banking.yaml
securityDefinitions:
oauth-1:
type: oauth2
scopes:
premier: Saving & Checking
x-scopeValidate:
url: https://scope-service/enforcement
GET /accountInfo
X-IBM-Client-Id: 88
Authorization: Bearer 2YotnFd7i4kd
API Connect verifies the token.
If valid, check access_token scope against the
api's requirement. If scope check is verified,
proceed to additional verification.
POST /enforcement HTTP/1.1
Host: scope-service

If API Connect receives HTTP 200, any HTTP headers in the response that start with "x-" will be accessible at `oauth.advanced-consent.<value>`
For the above example, `x-extra-data` is accessible at `oauth.advanced-consent.x-extra-data`.
If other than HTTP 200 is returned, it has the same effect as if the access token does not contain neccesary permissions to access the resource.

Consumer API enforcement

Standard scope validation
To access the API /getaccount the application must send a **GET** request with an access token that contains the scope, or scopes, defined in the OAuth provider. If the request doesn't contain a scope, you must specify a default scope to use. If no default scope is defined, and the request doesn't contain a scope, an invalid scope error is returned for the request.

```
GET /getaccount
HTTP/1.1
Host: server.example.com
X-IBM-Client-Id: 8888-8888-8888
Authorization: Bearer AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ
```

The following application OpenAPI file secure-banking.yaml defines the scope, or scopes, that must exist in the token to be granted access to the API /getaccount.

`secure-banking.yaml`

```
securityDefinitions:
   scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
security:
  - scope-only:
      - checking
  - scope-only:
      - saving
      - mutual
```

In the examples, the access token **AAEkNjVkOWIyYjgtOWY5ZS00YWQwLWIyYzktZ** is able to access the API because it contains one, or a combination of **scope-only** that is defined in secure-banking.yaml such as:

- **checking**
- **saving mutual**
- **checking saving mutual**

Advanced Scope Check
Administrators can enable an additional scope check by configuring the consumer API property Advanced Scope Check URL that becomes **x-scopeValidate** as shown in the following OpenAPI file example.

```
securityDefinitions:
  advanced-scope-only:
    type: oauth2
    description: ''
    flow: implicit
    authorizationUrl: ''
    scopes:
      checking: 'Checking Account'
      saving: 'Saving Account'
      mutual: 'Mutual Fund Account'
    x-scopeValidate:
      url: 'https://advanced-scope-check.bk.com/validate-scope'
      tls-profile: 'ssl-client'
```

After API Connect successfully verifies the access token against any scope requirement, API Connect will make an **HTTP POST** request to the **x-scopeValidate** endpoint similar to the following example. Response code `HTTP 200` from the endpoint indicates a success. Any other response code, or a connection error, is treated as a permission error for the token.

```
     POST /validate-scope?app-name=..&appid=..&org=..&orgid=..&catalog=..&catalogid=..&transid=..
HTTP/1.1
     Host: advanced-scope-check.bk.com
     Content-Type: application/json

   {"context-root" : checking,
    "resource" : accountinfo,
    "method" : GET,
```

```
    "api-scope-required" : [jointaccount],
    "access_token" : {"client_id" : "2cd71759-1003-4a1e-becb-0474d73455f3",
                      "not_after" : 174364070,
                      "not_after_text" : "2017-07-11T02:27:50Z",
                      "not_before" : 174360470,
                      "not_before_text" : "2017-07-11T01:27:50Z",
                      "grant_type" : "code",
                      "consented_on" : 1499736470,
                      "consented_on_text" : "2059-07-11T01:27:50Z",
                      "resource_owner" : "cn=spoon,email=spoon@poon.com",
                      "scope" : "jointaccount mutual",
                      "miscinfo" : "[r:gateway]"
                    }
}
```

An example of successful response follows.

```
    HTTP/1.1 200 OK
    Cache-Control: no-store
    Pragma: no-cache
    X-Custom-For-Assemble-Process: audit
```

Any HTTP response header that begins with "**x-**" is kept as the context variable **oauth.advanced-consent**. Based on the example successful response, **X-Custom-For-Assemble-Process: audit** becomes `oauth.advanced-consent.x-custom-for-assemble-process`, and can be accessed in the assemble step.

Additional validation options
You can optionally use additional fields for validation:

Request Header
: Defines the regular expression to match against **request** headers. Matching headers are included in the request to the advanced scope validation endpoint.

Response Context Variable
: Defines the regular expression to match against **response** headers. Matching headers are saved as context variables in the format **oauth.advanced-consent.***.

- IETF RFC 6749

Tokens

Tokens can be managed using refresh tokens and revocation URLs. You can extend the life of tokens using refresh tokens. You can end the life of a token by specifying a revocation URL.

This section contains information regarding token management, including refreshing and revoking tokens, redirecting, and managing tokens with the DataPower Gateway.

- **Refresh tokens**
  If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.
- **Token revocation**
  In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.
- **Authenticating and authorizing through a redirect URL**
  You can use a service that is hosted externally from IBM API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.
- **Token management with the DataPower Gateway (v5 compatible)**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.
- **Token management with the DataPower API Gateway**
  API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Refresh tokens

If you are using OAuth authentication, you can enable refresh tokens. Refresh tokens are issued to the client to obtain a new access token when the current access token becomes invalid or expires, or to obtain additional access tokens with identical or narrower scope.

When you are using OAuth authentication, API requests must include a valid access token, by using the Authorization HTTP header. Access tokens that are issued by the IBM® API Connect Token Endpoint are valid for 3600 seconds (1 hour) by default, as indicated by the expires_in property that is returned on the token request. The following code block shows an example API request with an Authorization header:

```
GET /bankingApi/accountSummary?client_id=32427ce5-bb7c-48a7-9de3-4bb629091103
HTTP/1.1
Accept: application/json
Host: api.ibm.com
Authorization: Bearer AAEFYylhbGxlhdS5nVX4x6iTL2sb3ymBivQb...
```

After an access token expires, if the option is enabled in the OAuth provider configuration Tokens > Refresh tokens screen, the application uses refresh tokens. Each refresh token is valid for approximately 31 days after it is issued (or for the Time to Live time period specified) and can be used only once to request a new access token. Along with the new access token, a new refresh token is also returned. For details on how to enable refresh tokens, see Configuring a native OAuth provider.

If the access token is expired and the application does not have a refresh token, it must restart the OAuth exchange by using the choice of Grant Type(s) allowed by the OAuth provider.

Token revocation

In IBM® API Connect, you can revoke or refresh tokens. If necessary, you can also revoke all tokens that are issued to a specific client ID or a resource owner.

Token revocation using an external third party service

This topic describes token revocation using a third party, external service. This option is configured in the Native OAuth provider, using the Token Management > Type = Third party screen. The revocation URL is an endpoint that links to an external service which contains information about access or refresh tokens. API Connect is involved in the initial creation and validation of tokens. When an OAuth revocation URL is present, API Connect calls the URL to determine if the associated token can be trusted. The token server then checks a token *blocklist* (a data store of inactive tokens) to ensure that the token is still valid. If the token is still valid, API Connect continues the processing.

Examples

A number of revocation examples follow. The first shows a sample fetch request and the response from a remote revocation URL.

GET request and response

In this example, an API Gateway server issues a GET request to the Revocation URL and receives a result. It shows that different resource owners (Laura and Emily) can revoke all tokens when using the same application (client ID).

Request:

```
<?xml version="1.0" encoding="UTF-8"?>
GET <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Accept: application/xml; text/xml
```

Response:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>

<!--
Access Tokens and/or Refresh Tokens that are revoked can be individually listed.
To keep this list small, please only include access tokens and refresh tokens that are valid.
For access tokens, any token older than 20 minutes is no longer valid.
For refresh tokens, any token older than 44700 minutes is no longer valid.
-->

<token type="access">AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1...</token>
<token type="refresh">fZaRlVbnPSc1UGTjCRdq4mPbOosD2+aZIKbJ6bTeW...</token>

<!--
If a resource owner has revoked all tokens issued to a given application, please
list them as shown here.
-->

<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">laura</resource-owner>
<resource-owner client-id="760d75a2-44b1-4485-8c6f-0d264fcf7398">emily</resource-owner>

</oauth-revocation>
```

POST request and response

The next example shows a post request and response.

Request:

```
POST <revocationURL> HTTP/1.1
User-Agent: IBM-APIManagement/4.0
Content-Type: application/xml

<?xmlversion="1.0" encoding="UTF-8"?>
<token>
   <token_type>bearer</token_type>
   <access_token>AAENYy1hbGwtcmVmcmVzaOfNeQKX8ZeojsBY9v0FI7/OerQvzKHq...</access_token>
   <expires_in>3600</expires_in>
   <scope>3600</scope>
   <resource-owner>alice</resource-owner>
   <client_id>83d9cdcd-ba72-4d00-abae-005da8da5fb1</client_id>
</token>
```

Response:

```
HTTP/1.1 200 OK
```

Provide token information on revocation request

In this example, the application calls an API and passes a bearer token. In response, the Gateway fetches the revocation URL and provides information on the token being verified.

Gateway:

```
GET  <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Alternatively, the same process occurs when using a refresh token to issue a new access token. The application sends a refresh request to the token service. The Gateway then fetches the revocation URL, providing information on the refresh token being verified.

Gateway:

```
GET  <revocationURL>GET  HTTP/1.1
refresh-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Note: If you are using a third party OAuth provider then, for API Calls with bearer tokens, when Introspect URL is enabled on the API, the revocation URL is not applicable. Instead, the third party endpoint must validate the token and also check for revocation before returning a `200 OK` response to the Gateway.

Revoking tokens issued to Alice up to and including a specific date

On May 1st, Alice loses her phone and needs to reset her password. As a result, the token provider wants to revoke every token issued before Alice lost her phone. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-05-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

Revoking all tokens issued up to and including a specific date

Under certain catastrophic conditions, you may need to revoke all tokens issued up to and including a specific date, for example, May 1st. In this example, the Gateway sends a `GET` request to the revocation service. The revocation service replies confirming revocation of the specified tokens.

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
<?xml version="1.0" encoding="UTF-8"?>
<oauth-revocation>
  <everytoken before="2015-05-01T09:30:10Z" />
<oauth-revocation>
```

Putting it all together

The following shows the examples contained in this topic executed in a single action:

Gateway:

```
GET <revocationURL>HTTP/1.1
access-token: AAETb2F1dGgtcmV2b2tlLWN1c3RvbfZaRlVbnPSc1
client-id: 760d75a2-44b1-4485-8c6f-0d264fcf7398
resource-owner: alice
```

Revocation Service:

```
HTTP/1.1 200 OK
Content-Type: application/xml
Cache-Control: public, max-age=120
Date: Fri, 08 May 2015 21:49:03 GMT

<?xml version-"1.0" encoding="UTF-8"?>
<oauth-revocation>
  <resource-owner before="2015-04-08T09:30:10Z">mary</resource-owner>
  <resource-owner before="2015-04-12T09:30:10Z">john</resource-owner>
  <resource-owner before="2015-04-13T09:30:10Z">kevin</resource-owner>
  <resource-owner before="2015-04-01T09:30:10Z">alice</resource-owner>
<oauth-revocation>
```

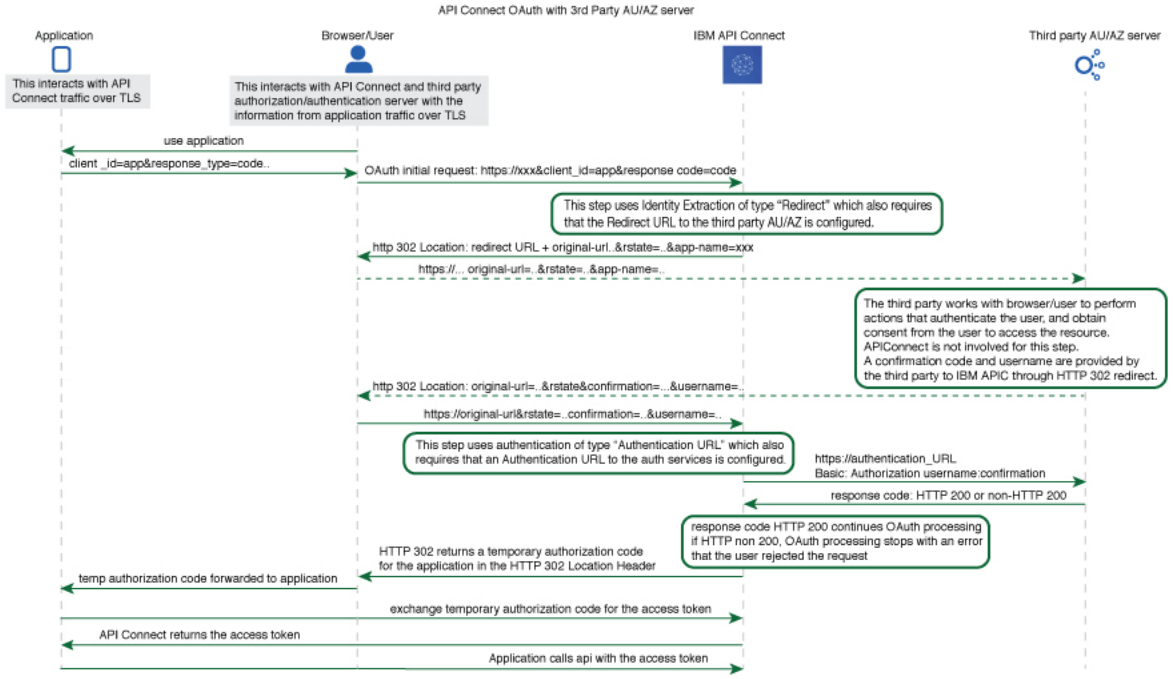
Notes:

- In the previous example, there are no entries older than one month in the response (the maximum life of a refresh token).
- Each response is cached for up to two minutes according to response's directive.
- The `before` attribute uses the `xs:dateTime` syntax.

Authenticating and authorizing through a redirect URL

You can use a service that is hosted externally from IBM® API Connect to collect authentication and authorization details from your user when an application requests access on that user's behalf.

Before you begin



To complete this task, you will need to either create or have created an OAuth security definition that uses Implicit grant type or Access Code (Authorization Code) grant type. For more information, see Creating an OAuth security definition.

About this task

If you use methods for authentication that are not supported by API Connect, you can redirect users to a suitable URL at which they can authenticate. The user is then returned to the OAuth process after authentication and authorization have been confirmed.

The following illustration indicates the transaction flow for third party authentication.

Figure 1. Third party authentication (AU) and authorization (AZ) transaction flow

1. The application initiates a request to access an API protected with a third-party entity. API Connect redirects the application with an **`HTTP 302`** redirect based on **`identity extraction -> redirect -> redirect-url`**, for user authentication (and optional authorization).
2. The application communicates directly with the third-party entity to gather user identity. API Connect is not involved in this communication. After the third-party entity finishes processing authentication (and optional authorization), it returns an **`HTTP 302`** redirect that uses the **`original-url`** from the request, with the username and confirmation code appended.
3. API Connect receives the request that includes the username and confirmation code, and communicates with the authentication URL, based on **`authentication -> x-ibm-authentication-url`**, to confirm user identity before the request is completed.
4. An **`HTTP 200`** response from the third-party entity allows API Connect to continue the OAuth 2.0 request process as if the owner is authenticated. The request is then processed according to the **`grants`** type.
   - **`- accessCode`** returns a temporary code to the application.
   - **`- implicit`** returns the access token to the application.

   For any response other than HTTP 200, the request fails with a statement added to the error log.

Procedure

To create an external form, and to indicate the URL to which API Connect will redirect users, complete the following instructions:

1. Create your service for authentication and authorization. You will use the URL of the landing page of this service as your redirect URL.
   a. To include elements in your form that are provided by API Connect, use the following query parameters from the URL that your user is redirected to.
   Note: With the exception of **`original-url`**, none of these parameters are included in the URL automatically; you must add them as required.

   app-name
   : The name of the application requesting access, as provided through the Developer Portal.

   appid
   : The id of the application requesting access.

   catalog
   : The name of the catalog where the product is being used by the application.

   catalogid

The id of the catalog where the product is being used by the application.

catalogtitle
: User-friendly display name for the catalog.

org
: The name of the consumer organization that hosts the application.

orgid
: The id of the consumer organization that hosts the application.

orgtitle
: User-friendly display name for the organization.

original-url
: The original URL that the user was directed to by the application, including query parameters from the original URL that are necessary for standard OAuth 2.0 requests. You can include these parameters in your service to provide information to the user. Additionally the state_nonce is appended. The state_nonce is a hash code generated by API Connect for verification purposes. The URL is URL-encoded and should be decoded before further use, the **`state_nonce`** should remain unchanged.

provider
: The name of the API provider organization.

providerid
: The id of the API provider organization.

providertitle
: User-friendly display name for the provider organization.

requested-scope
: [optional] If Application Scope check is enabled and replaces the **`scope`** from the initial application request, this field holds the **`scope`** value from the initial application request, and the new replacement scope value is put into **`original-url`**.

transid
: transaction id used in the GW for the transaction which trigger this call

The URL to which the user is sent to when they are redirected to your page has the following form:

```
Redirect_URL?original-url=Original_URL&state_nonce=R_State&app-name=Application_Name
```

where all variables are as described previously. The Redirect URL does not have a size limit enforced by API Connect.

b. Create the stages of authentication, authorization, and any intermediate stages that you require to take place before you allow access to the application. Upon completion of these stages, redirect the user to the *Original_URL* and append a user name, their confirmation code, and the application name to be evaluated for access grant or denial by API Connect. The confirmation code does not have a size limit enforced by API Connect.
Original URL requires the following form:

```
Original_URL&username=User_Name&confirmation=Confirmation_Code
```

where all variables are as described previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=spoon&confirmation=12345678
```

c. To send your own error responses after the authentication and authorization service, redirect the user to the *Original_URL* and append an error code. You can also append a user name. Use the following form:

```
Original_URL&username=User_Name&error=Error_Response
```

where *Error_Response* is the message you wish to send and all other variables are described as previously.

For example:

```
https://your_gateway.com/your_org/your_catalog/your_api/oauth/authorize?
response_type=code&redirect_uri=https://example.com/redirect&scope=/your_api&client_id=5af57a4a-6db9-4141-ad08-
5709432af66e&state_nonce=HoIbRG+6bZtqlB7LDkq4gjlD3SHKglCbnYdHs/bMz2Y=&username=User&error=access_denied
```

2. Create a service to validate the confirmation code and user name. API Connect makes a GET call to your authentication URL after the user is redirected back to the authorization URL. When the call is made, it includes in its authorization header the user name and confirmation code you supplied previously. Confirm that these are correct and respond with an HTTP success code such as `200 OK` if you want to allow access, or non-`200 HTTP` response code, such as `401 Unauthorized` to deny access.
3. In your OAuth provider configuration, supply the redirect URL that is used in Step 1 and the authentication URL that is used in Step 2.
For more information on configuring an OAuth Provider, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Token management with the DataPower Gateway (v5 compatible)

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

In order to manage tokens with the DataPower® Gateway (v5 compatible), you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Also, the DataPower quota enforcement server must be enabled on the DataPower Gateway to use the distributed cache to manage tokens. See Quota enforcement.

Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

When distributed cache support is enabled, replay protection is provided across the gateway cluster through the quota enforcement server. This support ensures that the same token cannot be reused across the members of the quota enforcement peer group.

Important:
If you have a cluster of DataPower Gateway servers, the OAuth data synchronization behavior across the servers depends on whether or not you enable revocation:

- If you enable revocation, API Connect uses the DataPower quota enforcement server, and OAuth data is synchronized across the servers. If an access token is obtained from one server, the OAuth data synchronization ensures that the same authorization code cannot be used to obtain an access code from another server. You must ensure that the DataPower quota enforcement server is configured.
- If you disable revocation, API Connect does **not** use the DataPower quota enforcement server and OAuth data does not synchronize across the cluster of DataPower Gateway servers. Therefore, to prevent the same authorization code being used to obtain an access code from more than one server you must configure DataPower to synchronize OAuth data across the servers, by using the DataPower Gateway console.

To configure DataPower to synchronize OAuth data, ensure that the DataPower quota enforcement server is configured. For more information, see Configuring the quota enforcement server.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user `cn=spoon,o=ibm` with username `spoon` and password `spoon` using a registered administration application of `5287fe53-8747-438a-8262-681ec75b79c5`.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

[

{

"clientId": "5287fe53-8747-438a-8262-681ec75b79c5", => same client id as request

]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client_id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

    { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an **access_token**, or **refresh_token** with **token_type_hint** as shown in the following examples:

Revoke **access_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

   Host: apic.ibm.com

      x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
      x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
     Content-Type: application/x-www-form-urlencoded

     token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
     Content-Type: application/json;charset=UTF-8
     Cache-Control: private, no-store, no-cache, must-revalidate
     Pragma: no-cache

    { "status": "success" }
```

Token management with the DataPower API Gateway

API Connect can use the DataPower distributed cache to manage the token lifecycle that includes when to revoke access rights.

Note: The steps described in this topic are required if you are using the DataPower® OVA or appliance version of the gateway. For the API Connect supplied Kubernetes deployment, the API Security Token Manager is preconfigured provided that, in the gateway service custom resource file, v5 compatibility mode is disabled and the token management service is enabled:

```
      .
      .
      .
spec:
      .
      .
      .
  apicGatewayServiceV5CompatibilityMode: false
  tokenManagementService:
    enabled: true
      .
      .
      .
```

For more information, see Installing the DataPower Gateway subsystem.
Token management relies on gateway-peering to distribute the cache for revocation details within a gateway cluster node, and does not propagate across different gateway clusters. In order to enforce token management across different gateway clusters, you must use the external token store and set the Token Management Type to **External** in your native OAuth provider configuration.

In order to manage tokens with the DataPower API Gateway, you must set the Token Management Type to Native in your Native OAuth provider configuration. See Configuring token management and revocation for a native OAuth provider when using Cloud Manager or Configuring token management and revocation for a native OAuth provider when using API Manager.

Note: This setting is also required when you use a third-party OAuth provider and **`Introspect cache type`** is set to **`protocol`** or **`Time to live`**.
For token management with the DataPower API Gateway, you must configure the API Security Token Manager on the gateway. Complete the following steps:

1. Log in to the DataPower administration console, selecting apiconnect for the domain, and WebGUI for the Graphical Interface.
2. In the search box, enter API Security Token Manager, then click on the API Security Token Manager link that displays in the search results.
3. For the Administrative state, select enabled.
4. Click the + icon alongside the Gateway Peering field to create a new gateway peering object.
5. Provide a Name and a Local address.
6. In the Local port and Monitor port fields, provide values that aren't already in use by services for the Local address.
7. Ensure that Peer group mode is selected.
8. Alongside the Peers field, use the add button and accompanying field to add at least two peers, to ensure that quorum is achieved.
9. If the Enable SSL option is selected, select a value for the Identification credentials.
10. For Persistence location, select a setting other than memory.
11. When done, click Apply.
12. Repeat steps 1 to 11 for each DataPower API Gateway in the peer group.
13. When done, click Apply, then click Save Configuration to save your changes.

For more information, see Defining the API security token manager and Creating a gateway peering instance.

Resource owner revocation

When Resource owner revocation path is selected in the Token Management screen, the configuration inserts two REST API calls to /oauth2/issued.

- An HTTP GET operation that retrieves a list of all granted permissions for a specific user.
- An HTTP DELETE operation that revokes an application for a specific user.

The setting inserts header-based security definitions of client ID and client secret as shown in the **View permissions example**. The API call to revoke a given application for a given user is shown in the **Revoke permissions example**.

View permissions example

To list all the applications granted by user **`cn=spoon,o=ibm`** with username **`spoon`** and password **`spoon`** using a registered administration application of **`5287fe53-8747-438a-8262-681ec75b79c5`**.

- Request:

```
GET /oauth2/issued
HTTP/1.1
       Host: apic.ibm.com
       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
       Authorization: Basic c3Bvb246c3Bvb24=
```

- Response:

```
HTTP/1.1 200 OK

Content-Type: application/json;charset=UTF-8

Cache-Control: no-store

Pragma: no-cache

[

{

"clientId": "5287fe53-8747-438a-8262-681ec75b79c5", => same client id as request

"owner": "cn=spoon,o=ibm",
```

```
"clientName": "PetStore Application",

"scope": "listpet",

"issuedAt": 1503327054,

"consentedOn": 1503327054,

"expiredAt": 1503330654,

"refreshTokenIssued": false,

"appId": "d2031f0f27339315333734ab9",

"org": "PetStoreOrg",

"orgTitle": "Katie Pet Grooming Inc",

"orgId": "5887803de4b06e6998c4b2c7",

"provider": "SuperStore",

"providerTitle": "Simon SuperStore",

"providerId": "5887803de4b06e6998c4b2c7",

"catalog": "publicapi",

"catalogTitle": "For public",

"catalogId": "5887803de4b06e6998c4b2d3"

} => delete second item

]
```

Revoke permissions example

To revoke application `a8746323-9825-a842-8736-abd8202356ac8` by owner `cn=spoon,o=ibm`.

- Request

```
DELETE /oauth2/issued?client_id=a8746323-9825-a842-8736-abd8202356ac8

HTTP/1.1

Host: apic.ibm.com

x-ibm-client-id: a8746323-9825-a842-8736-abd8202356ac8 => same client id as delete request

x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7

Authorization: Basic c3Bvb246c3Bvb24=
```

- Response

```
HTTP/1.1 200 OK
Content-Type: application/json;charset=UTF-8
Cache-Control: private, no-store, no-cache, must-revalidate
Pragma: no-cache

     { "status": "success" }
```

Client revocation

When Client revocation path is selected in the Token Management screen, the result is the following:

This option inserts one REST API call to /oauth2/revoke, which supports OAuth 2.0 IETF RFC 7009. An HTTP POST operation that an application can send to this API to revoke either an `access_token`, or `refresh_token` with `token_type_hint` as shown in the following examples:

Revoke `access_token`

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=access_token&token=AAIHZGVmYXVsdD1-KqwD0Yc3EDn94lSWX14xuR....
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Revoke **refresh_token**

- Request:

```
POST /oauth2/revoke
HTTP/1.1

    Host: apic.ibm.com

       x-ibm-client-id: 5287fe53-8747-438a-8262-681ec75b79c5
       x-ibm-client-secret: E2qM6mG2bX2uC1xT2iN1uU6bT5cV4dN7nW5kM5uP8vL3uF3cT7
      Content-Type: application/x-www-form-urlencoded

      token_type_hint=refresh_token&token=........
```

- Response:

```
HTTP/1.1 200 OK
      Content-Type: application/json;charset=UTF-8
      Cache-Control: private, no-store, no-cache, must-revalidate
      Pragma: no-cache

     { "status": "success" }
```

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service that manages user authentication, and optionally provides additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes **cn=spoon,o=eatery**. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the **access_token**.
- Overriding the **scope** that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the **scope** value that the application receives. For example, you can provide a specific resource owner an account number within the **scope** header response for use in future processing steps.

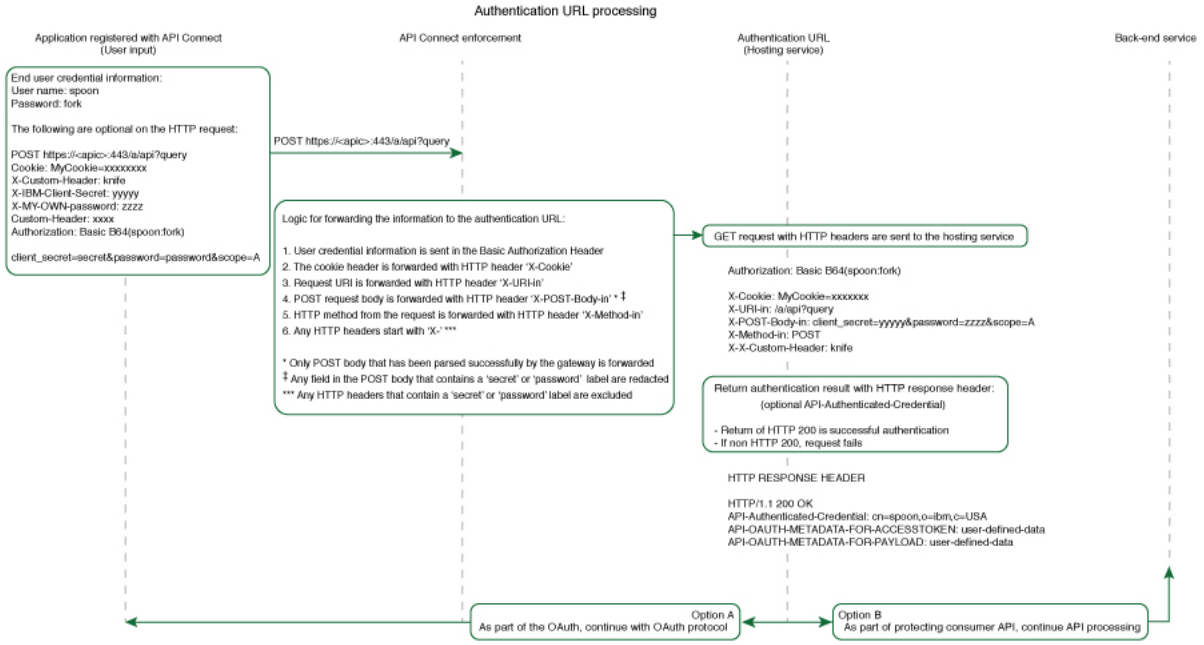
When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use **cn=spoon,o=eatery** as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.



API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested **scope** from the application. For more information, see Scope. The response header is:

```
x-selected-scope
```

If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Custom forms for user security

You can create custom forms for the authorization and identity extraction phase of OAuth.

About this task

The Native OAuth provider configuration provides the capability for requiring additional authentication and authorization steps for user security. Custom HTML forms may be created to extract the identity of the user and to authorize the user. This capability applies to Implicit, Resource owner password, and Access code grant types.

- **Creating a custom HTML login form for user security**
  Custom HTML forms can be created for user security during the identity extraction stage in OAuth.
- **Creating a custom HTML authorization form for user security**
  Custom HTML forms can be created for user security during the authorization stage in OAuth.

Creating a custom HTML login form for user security

Custom HTML forms can be created for user security during the identity extraction stage in OAuth.

Before you begin

The Native OAuth provider configuration includes Identity Extraction when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to extract the user credential and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. For more information, see Configuring a native OAuth provider. This topic describes how to create the Custom HTML form for identity extraction.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form for signing in to the service provided by the API. You can present a custom form or a default form. Your custom form must fulfill certain requirements.

Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom sign-in form for your Native OAuth provider, complete the following steps:

1. Create a well formed XHTML document that will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example:

```
<form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
```

3. Create a text input field that is named `username` and create a password input field named `password`.
4. Add the line `<EI-INJECT-HIDDEN-INPUT-FIELDS>`. This third element is a placeholder that API Connect replaces with input fields to complement the user-submitted data.
5. Create a button to initiate the sign-in process.
   For example:

```
<button
id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_button" type="submit" name="login" value="true">Log in</button>
```

6. Optional: Add text that is displayed the first time that the user visits the sign-in page. Use the tag `<EI-LOGINFIRSTTIME>` for the text that you want to display.
7. Optional: Add text that appears when the user is returned to the sign-in page if they fail to authenticate. Use the tag `<EI-LOGINFAILED>` for the text that you want to display.
8. Optional: Have an error message displayed when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<EI-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
9. Optional: You can add elements that are loaded from external sources, such as images or JavaScript.
10. Insert spacing and other features as you require. Completing Steps 1 through to 8 results in a form similar to the following example:

```
<html lang="en" xml:lang="en">
  <head><meta http-equiv="Content-Type" content="text/html; charset=UTF-8"/></head>
  <body>
    <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
      <h1>Please sign in</h1>
      <p>Username </p>
      <p ><input type="text" name="username" required="required" /> </p>
      <p>Password </p>
      <p ><input type="password" name="password" required="required" /> </p>
      <EI-INJECT-HIDDEN-INPUT-FIELDS/>
      <p > <button
id="_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.apionprem.doc_oauth_custom_login_form_login_button" type="submit" name="login" value="true">Log in</button> </p>

      <EI-LOGINFIRSTTIME>
        <p>If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFIRSTTIME>

      <EI-LOGINFAILED>
        <p >At least one of your entries does not match our records.
          If you have forgotten your user name or password, contact your system administrator.</p>
      </EI-LOGINFAILED>

      <EI-INTERNAL-CUSTOM-FORM-ERROR/>

    </form>
  </body>
</html>
```

11. Make your form available at a URL of your choice.
12. If you have not already done so, configure your Native OAuth provider to use a Custom HTML form for identity extraction and provide the URL at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Creating a custom HTML authorization form for user security

Custom HTML forms can be created for user security during the authorization stage in OAuth.

Before you begin

The Native OAuth provider configuration includes user authorization when using the Implicit, Access code, or Resource owner password grant types. You have the option to select how to authorize application users and one of the choices is Custom HTML Form. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager. This topic describes how to create the Custom HTML form for authorization.

About this task

During three-legged OAuth definitions (Implicit flow, Resource owner password flow, and Access (Authorization) code flow, the user is presented with a form through which they grant permission to an application to access their data through the API on their behalf. You can present a custom form or a default form. Your custom form must fulfill certain requirements.
Important: The fields used by IBM® API Connect to inject information into your form have case-sensitive field names.

Procedure

To create a custom authorization form for your Native OAuth provider, complete the following steps:

1. Create a well-formed XHTML document. This will be parsed and transformed by API Connect to inject hidden fields.
2. For your XHTML form, set the method as `POST`, the encoding type as `application/x-www-form-urlencoded`, and the action as `authorize`. Add any other parameters that you require.
   For example:

   ```
   <form method="POST" enctype="application/x-www-form-urlencoded" action="authorize">
   ```

3. Add the line `<AZ-INJECT-HIDDEN-INPUT-FIELDS/>`. This line is a placeholder that API Connect will replace with input fields necessary for the completion of the OAuth process.
4. Create two buttons with the following code so that the user can grant or deny permission. Edit the text to suit your preferences.

   ```
   <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
   <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
   ```

5. Optional: Display an error message when an error in the custom form prevents it from being displayed to the user correctly. Use the tag `<AZ-INTERNAL-CUSTOM-FORM-ERROR/>`; the message text is generated automatically. You should detect such errors during testing to prevent this error message being displayed to the end user.
6. Optional: You can add to the form HTML elements that will load features from external sources, such as images or JavaScript.
   For example, `<script src="http://www.example.com/example.js" />`
7. Insert spacing and additional elements as you require. Completing Steps 1 through to 6 results in a form similar to the following example:

   ```
   <html lang="en" xml:lang="en">
     <head><title>Request for permission</title></head>
     <body class="customconsent">
       <div>
         <div>
           <form method="post" enctype="application/x-www-form-urlencoded" action="authorize">
             <AZ-INJECT-HIDDEN-INPUT-FIELDS/>
             <p>Greeting..</p><DISPLAY-RESOURCE-OWNER/>
             <p>This app </p><OAUTH-APPLICATION-NAME/><p> would like to access your data.</p>
             <div>
               <button class="cancel" type="submit" name="approve" value="false">No Thanks</button>
               <button class="submit" type="submit" name="approve" value="true">Allow Access</button>
             </div>
           </form>
         </div>
         <AZ-INTERNAL-CUSTOM-FORM-ERROR/>
       </div>
     </body>
   </html>
   ```

8. Make your form available at a URL of your choice.
9. If you have not already done so, configure your Native OAuth provider to use a Custom HTML Form for authorization for User Security. Provide the URL as the endpoint at which your form is available. For more information, see Configuring a native OAuth provider when using API Manager or Configuring a native OAuth provider when using Cloud Manager.

Securing an API with a JSON Web Token

There are two methods to secure your API with a JSON Web Token. You can use the **jwt-generate** command, or you can use a token that has been generated external to IBM® API Connect.

About this task

JSON Web Token (JWT) is an OAuth 2.0 compliant method of authentication that can be useful to secure your API in API Connect.

You can secure your API with a JSON Web Token by using either of the following methods:

- Generate a token through the **jwt-generate** command, and then augment the response payload with your generated token replacing the `id` token.
- Use a token that was generated outside of API Connect and include it into the response payload, by using the metadata URL.

Procedure

Create a **jwt-generate** policy in the assembly.

a. In API Manager, open the Assembly tab.
b. Add a jwt-generate policy to the assembly for the API.

Troubleshooting OAuth

You can find the answers to some common questions in the Developer Portal, or in support communities and forums in DeveloperWorks, on GitHub, or on YouTube.

You can use the following links to go to the topics:

- OAuth 2.0 support in the developer portal test tool
- OAuth requires quorum in a multi-node cluster

OAuth 2.0 support in the developer portal test tool

OAuth 2.0 support is exposed as an API through the provider OpenAPI definition. You can use the test tool that is included with API Connect to test the OAuth 2.0 configuration. For more information, see Testing an API using the Developer Portal test tool.

OAuth requires quorum in a multi-node cluster

In a multi-node cluster, OAuth operations will fail if quorum is lost. Quorum requires that the number of active nodes is greater than 50% of the total number of nodes in the cluster.

Configuring the cloud settings

Before you can add a provider organization to your cloud, you must specify your cloud settings to configure an email server for notifications as well as user registry options and catalog defaults.

The cloud settings let you define basic configuration for your deployment. To view the current settings, log in to Cloud Manager and click  in the navigation pane.

Tip: When you are familiar with the cloud settings, you can modify them using the Toolkit command-line interface instead of the user interface.
Visit the following pages to configure settings:

Overview
: Provide a title and description for your cloud administrator organization. For more information, see Change the name of your cloud.

Onboarding
: Specify time-out settings for onboarding invitations, password resets, access tokens, and refresh tokens. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
For more information on setting timeouts, see the following topics:

  - Configuring invitation timeouts
  - Configuring the password-reset notification and timeout
  - Configuring timeouts for access tokens and refresh tokens

User Registries
: Configure one or more user registries to authenticate users of Cloud Manager or API Manager. The user credentials for all users who login to each applications must be stored in the specified registries. For more information on configuring user registries, see Selecting user registries for Cloud Manager and API Manager.

Roles
: Create roles and assign them to members of the Admin organization to specify which tasks members are authorized to perform. For more information on assigning roles, see Administering members and roles.

Role Defaults
: The Role Defaults for the Admin organization are not configurable, but you can customize the base roles for provider organizations and consumer organizations. For more information on customizing base roles, see Role Defaults overview.

Endpoints
: View the list of endpoints configured for API Manager, provider APIs, and consumer APIs during the installation process.

Notifications
: Select the email server for your on-premises cloud notifications, configure notification settings, and specify the sender name and email address to be included in the emails. You can also preview and customize email templates used for notifications. For more information on setting up notifications, see Setting up notifications.
Note: Be sure to configure the email server, because it is needed for sending invitations and other notifications to users.

Catalog Defaults
: Specify one or more gateway services to be provided to every Catalog by default, so that Products (which contain APIs) can be made available to users. When a new Catalog is created in a provider organization, it is assigned to the default gateway service. Any changes you make to these settings do not affect existing Catalogs.
For more information on selecting gateway services, see Configuring the default gateway services for Catalogs.

Audit Setting
: Configure auditing settings to monitor API calls and log information about the calling users, the time of each call, and the activity involved in each event. The audit focuses on "who" did "what" and "when", including the request payload and the result of the operation. All create, update, and delete operations are audited. Generally, read operations are only audited if the calling user logged in with an OIDC Provider user registry. For more information about configuring the use of auditing, see Configuring audit logging to monitor user operations.

Use the following list to locate instructions for using specific cloud settings:

- **Change the name of your cloud**
  You can change the name of your cloud.
- **Configuring an email server for notifications**
  Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.
- **Setting up notifications**
  Select an email server and set up the "sent from" information for notifications.
- **Configuring invitation timeouts**
  You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.
- **Configuring API key settings**
  You can set the time period for when an API key expires, and optionally authorize it to be used multiple times.

- **Using the CLI to modify cloud settings**
  Use the toolkit CLI to edit the cloud settings.
- **Configuring Base64 encoding for temporary tokens**
  How to enable and disable Base64 encoding for temporary tokens.
- **Configuring the password-reset notification and timeout**
  Configure the time allowed for a user to reset a password, and customize the notification that the user receives.
- **Selecting user registries for Cloud Manager and API Manager**
  Select the user registries to authenticate users for Cloud Manager and API Manager.
- **Configuring timeouts for access tokens and refresh tokens**
  Configure timeout values for the access tokens and refresh tokens for user registries.
- **Viewing platform and UI endpoints**
  A view-only list of platform and UI endpoints is provided.
- **Configuring the default gateway services for Catalogs**
  Configure the list of default gateway services that are available to new Catalogs.
- **Managing the public/private key pairs for signing tokens**
  Manage the public/private key pairs that are used for signing tokens in API Connects.

Change the name of your cloud

You can change the name of your cloud.

About this task

You can change the name of your cloud using the Overview page.

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud settings:manage`

Procedure

Follow these steps to change the name of your cloud:

1. In the Cloud Manager, click Settings.
2. Select Overview..
3. Click Edit to change the name of your cloud.
4. Enter a Title and the name is auto-generated. Enter a brief Summary and click Save.

Configuring an email server for notifications

Connect to an email server in your API Connect on-premises cloud. The email server sends registration invitations and other event-driven emails. You must configure the email server before you add any provider organizations or register a Portal service. Otherwise, the owner of the organization will not receive the email with the details that they require to access the API Manager.

Before you begin

You must complete the tasks in the following section:

1. Defining your Cloud Manager topology

About this task

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator
- Topology Administrator
- Custom role with **`Settings:Manage`** permission

The email server sends invitation emails with activation links and other system messages. More than one email server may be configured in Cloud Manager, but only one email server may be selected as the active server to send notifications at any one time. For instructions on how to select the active email server and to view a list of the email messages that are sent, see Setting up notifications.
Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Procedure

To configure one or more email servers to use for email notifications in Cloud Manager, complete the following steps:

1. In the Cloud Manager, click Resources.

2. Choose Notifications.
3. Enter the values to configure the email server.

Field	Description
Title (required)	Enter a descriptive title for the email server. This title will display on the screen.
Name (required)	This field is auto-populated by the system and used as the internal field name.
Address (required)	IP address for the email server
Port (required)	Port that the email server runs on
Authenticate User	Enter a user name to use for authorization with the SMTP server. The user name is required if the SMTP server requires authentication.
Authenticate Password	Enter the password for the Authenticate User. This password is used for authorization with the SMTP server. The password is required if the SMTP server requires authentication.
TLS Client Profile (optional)	Select an optional TLS Client Profile that will be used to communicate with the email server if the Secure Connection option is selected.
Secure Connection	Select this option to specify that TLS security is used. The following conditions apply: • If this option is not selected then TLS security is not used even if the email server is configured to use the STARTTLS protocol. • If this option is selected and a TLS Client Profile is selected, that profile is used and the STARTTLS protocol configuration on the email server is honored. • If this option is selected and no TLS Client Profile is selected, the Default TLS client profile is used and the STARTTLS protocol configuration on the email server is honored.

4. You can send a test email to confirm that the email server is properly configured. Click Test email in the Test Connection panel to open a dialog window. Enter one or more valid email addresses in the Recipients field. Separate multiple recipients with commas. Click Send test email. Check that the test email was received by the recipients.
5. If the test email is successful, click Save to save the email server configuration. If the test is unsuccessful, check the configuration values and update as needed.
   Note: In order to send emails, you must select an email server as your active server in Settings > Notifications.

Results

The email server is configured.

What to do next

You must now select the email server to use as your active email server in Cloud Settings > Notifications. You can enter the sender information, and customize the email templates. For more information, see Setting up notifications.
Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Setting up notifications

Select an email server and set up the "sent from" information for notifications.

Before you begin

You must configure an email server to use for your notifications in Resources > Notifications, before you can set up the notification configuration in Settings > Notifications. See Configuring an email server for notifications for more information.

About this task

In Settings > Notifications, you select the email server that you want to use as the active server to send notification emails. An active email server is required to send email notifications. More than one email server may be configured in Cloud Manager, but only one email server may be selected to send notifications at any one time. The email server must be configured and selected for notifications before adding a Portal Service to your cloud.

You also configure the sender information to be included on all the emails and optionally, edit the standard text for the email templates.

One of the following roles is required to add roles to select the email server, enter the sender information, and edit the email templates:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

Note: If you do not select an email server for sending notification emails, it is not possible for a user to reset their password from either the Cloud Manager or API Manager login pages.

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Notifications.
3. To configure the active email server:
   a. Click Edit in the Sender & Email Server section.
   b. Select an email server in the list; a check mark is displayed next to the currently selected server.
   c. Click Save.
4. To delete an email server from the list, click the options menu next to the server name and select Delete.

5. To change the sender name and email address for notifications:
   a. Click Edit in the Sender & Email Server section.
   b. Fill in the Name and Email address that notifications will be sent from.
   c. Click Save.
6. To preview and edit the notification email templates, see Customizing email notification templates

What to do next

You can now create a provider organization.

- **Customizing email notification templates**
  API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

Customizing email notification templates

API Connect includes a set of email templates for invitations and other notification emails. You can preview the templates and customize the text if required. You can also style the notifications to match your business theme.

About this task

The API Connect emails are sent automatically when certain system events occur. The email templates are organized by scope, as explained in Table 1.

Table 1. Notification scopes

Scope	Events that trigger the notification
admin	Admin organization activities such as invitations, portal sign up, and password reset.
catalog	Activities related to Catalogs; for example: such as application life cycle events, invitations to catalogs, product approvals, and subscription approvals.
consumer	Activities to consumer applications and subscription requests in the Developer Portal, invitations to Consumer organizations, and password reset requests for Developer Portal accounts.
provider	Invitations
space	Invitations

Email notifications contain a sender name and address that's based on a hierarchical search of the configured sender details in API Connect. Depending on the email template being sent, the search can start at the Space level, and then go through the Catalog, Provider Organization, and the Cloud Manager levels. The sender details that are used will be the first set of configured details found during this hierarchical search. To view which search path API Connect takes when looking for the sender details for each notification template, see Configuring sender details for email notifications in the Managing your APIs section.

One of the following roles is required to configure email notifications:

- Administrator
- Owner
- A custom role with the `Cloud settings:Manage` permission

Note: You can also customize notifications by using the developer toolkit CLI, or by using the API Connect REST APIs. See Using the CLI to modify cloud settings, or API Connect REST APIs, for more information.
If you want to configure the notifications at the Provider Organization level, see Configuring notifications in the Managing your APIs section.

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Notifications.
   On the Notifications page, templates display in a list, sorted by scope. When selecting a template to modify, be sure to select the version that applies to the appropriate scope.
3. To preview the text for a template, select Preview from the actions menu next to the template name.
4. To edit the text for the template, either click the template name, or select Edit in the action menu.
   When a template is opened, an attempt is made to get the language from the browser setting, but if this isn't possible the template defaults to English.

   The text includes variables; for example, `{{catalog}}`. The notification text is based on Handlebars syntax. Most variables are enclosed in double curly braces `{{ }}`, but can be enclosed in triple curly braces `{{{ }}}` to disable HTML escaping, when the variable is a URL link for example. For more information on Handlebars, see https://handlebarsjs.com/.

   To obtain the complete list of variables that are available for a particular notification template, complete the following steps:
   a. Log in to the management server from the command line as a member of the cloud administration organization; for details, see Logging in to a management server. You can use the same management server URL, user name, and password in the login command that you use to log in to the Cloud Manager user interface.
   b. Enter the following command:

   ```
   apic notification-templates:get template_name --server mgmt_endpoint_url --scope cloud --subcollection template_scope
   --fields variables --output -
   ```

   where:
   - *template_name* is the name of the required notification template, as displayed in the Template column in the user interface.
   - *template_scope* is the scope name displayed in the Scope column alongside that template.

   For example:

   ```
   apic notification-templates:get member-invitation --server https://myserver.com --scope cloud --subcollection catalog
   --fields variables --output -
   ```

The variables that are available for the template are displayed, for example:

```
variables:
  - org
  - catalog
  - activationLink
  - expiresAt
  - originator
  - originatorFirstName
  - originatorLastName
  - originatorEmail
  - username
  - email
  - firstName
  - lastName
```

The **--output** - parameter causes the command output to be written to the command line. You can specify **--output** ***filepath*** to have the output written to a .yaml file at the specified location, or omit it altogether to have a file written to the current folder.

5. To view and edit the notification template in a different language, select one of the following supported languages from the View template in drop-down list:
   - Chinese (Simplified)
   - Chinese (Traditional)
   - Czech
   - Dutch
   - English (US English)
   - French
   - German
   - Italian
   - Japanese
   - Korean
   - Polish
   - Portuguese
   - Russian
   - Spanish
   - Turkish
6. Edit the Subject as required.
7. Select the Content type that you want to use for the template, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
8. Edit the body of the template as required.
   For HTML content, only the tags and their attributes that are shown in the following table are allowed.

Table 2. List of allowed HTML tags and their attributes

HTML tag	Attribute
<a>	**"class", "href", "hreflang", "style"**
****	**"class", "style"**
****	**"class", "style"**
<cite>	**"class", "style"**
<blockquote>	**"class", "cite", "style"**
<code>	**"class", "style"**
** **	**"class", "type", "style"**
** **	**"class", "start", "type", "style"**
** **	**"class", "style"**
<dl>	**"class", "style"**
<dt>	**"class", "style"**
<dd>	**"class", "style"**
<h1>	**"class", "id", "style"**
<h2>	**"class", "id", "style"**
<h3>	**"class", "id", "style"**
<h4>	**"class", "id", "style"**
<h5>	**"class", "id", "style"**
<h6>	**"class", "id", "style"**
<p>	**"class", "style"**
** **	**"class", "style"**
** **	**"class", "style"**
****	**"class", "style"**
<img>	**"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"**
<table>	**"class", "id", "style"**
<tr>	**"class", "id", "style"**
<td>	**"class", "id", "style"**

If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
Images can be used by adding a **** tag in the template. The **src** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.

9. Click Save when done.
   Note: Edits made to a template are saved only for the specific language version that is edited.

Related information

- Configuring notifications

Configuring invitation timeouts

You can set the time period for when registration invitations for Cloud Settings access and the Admin organization expire.

About this task

One of the following roles is required to change the name of your cloud:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

Follow these steps to set the invitation timeout:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the invitation timeout setting that you want to change:
   - Cloud Settings Invitation Timeout
   - Admin Organization Invitation Timeout
4. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
5. Click Save.

Results

Invitations contain a link, which expires after the specified the timeout. If the user does not register before the expiration, you can send a new invitation.

Configuring API key settings

You can set the time period for when an API key expires, and optionally authorize it to be used multiple times.

About this task

Applications exchange the API key exchange the API key for an access token.

Procedure

Follow these steps to set the API key timeout:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the API Key timeout setting.
4. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
5. Select Multiple use of apikey to allow applications to exchange the API key for an access token multiple times.
   By default, the API key can be used only once.

   To enable this setting with the CLI, set the **`api_key_multiple_uses`** field to **`true`**.

6. Click Save.

Results

API Key times out based on the set timeout value.

Using the CLI to modify cloud settings

Use the toolkit CLI to edit the cloud settings.

About this task

Some cloud settings can be modified in the Cloud Manager UI, but all settings can be modified with the toolkit CLI. You can modify the cloud settings configuration file and upload the changes, or issue commands to modify individual settings directly. If multiple people modify the cloud settings, any newer settings overwrite older settings regardless of the method used to update the settings.

For more information about working with the toolkit CLI, see the toolkit CLI reference documentation.

Procedure

1. Run the following command to log in to a management server as a member of the cloud administration organization:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For more information on logging in, see Logging in to a management server.

2. Optionally retrieve the current list of cloud settings with the following command:

   ```
   apic cloud-settings:get --server mgmt_endpoint_url --output -
   ```

   where *mgmt_endpoint_url* is the URL of the server where the cloud settings are stored.

3. Add or modify settings using one of the following methods:
   - Issue each setting from the command line.
     For simple changes, you can issue commands to modify settings without editing the configuration file.

     - Issue the following command to start the update process:

       ```
       apic cloud-settings:update --server mgmt_endpoint_url -
       ```

       where *mgmt_endpoint_url* is the URL of the server where the cloud settings are stored. Include the hyphen at the end of the command to indicate that input follows on the next command line.

     - Type the information for a single setting on one line, and press ENTER to submit it.
       Specify each setting on a single line and use the following format to specify the setting's name and value:

       ```
       setting_name: setting_value
       ```

       For example, the following command updates a single setting:

       ```
       apic cloud-settings:update --server mgmt_endpoint_url -
       refresh_expires_in: expiration time
       Ctrl+D
       ```

     - Type Ctrl+D to indicate that the data entry is complete, as shown in the example.
   - Upload a file containing the settings.
     If you have multiple settings or lengthy values to add or modify, you might prefer to make all of the changes at once by creating or modifying the configuration file and then uploading it.

     - Create a .yaml file with your settings.
       You can choose the file name but must use YAML format. The file can contain as few or as many settings as needed.

       Settings use the following format; notice that the setting's name must be enclosed in quotation marks as shown in the example. The last setting in the file does not end with a comma.

       ```
       "setting_name": setting_value,
       ```

     - Upload the file with the following command:

       ```
       apic cloud-settings:update --server mgmt_endpoint_url my_cloud_settings.yaml
       ```

     For information on using input files with the toolkit CLI, see ../com.ibm.apic.toolkit.doc/rapic_cli_command_line_input.html.

4. When you are ready to log out of the management server, use the following command:

   ```
   apic logout --server mgmt_endpoint_url
   ```

Results

The settings are cached for a maximum of five minutes, so you might experience a delay before your changes take effect.

Configuring Base64 encoding for temporary tokens

How to enable and disable Base64 encoding for temporary tokens.

About this task

You can enable or disable Base64 encoding for temporary tokens. Temporary tokens are invitations, and password reset tokens. When Base64 encoding is enabled, the temporary token is encoded in Base64 format. When Base64 encoding is disabled, the temporary token remains in the JSON Web Token (JWT) format, and means that the length of the URL that the user receives is reduced.

Base64 encoding is enabled by default.

One of the following roles is required to configure Base64 encoding:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

Follow these steps to configure Base64 encoding for temporary tokens:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Click Edit next to the Base64 encoding setting.
4. Select Enable to enable Base64 encoding, or Disable to keep temporary tokens in the JSON Web Token (JWT) format.
5. Click Save.

Results

You have successfully enabled or disabled Base64 encoding for temporary tokens.

Configuring the password-reset notification and timeout

Configure the time allowed for a user to reset a password, and customize the notification that the user receives.

Before you begin

Configure an email server that can be used for mailing notifications to users. If you do not configure an email server, a link cannot be send to a user who wants to reset a password. For information on configuring the email server, see Setting up notifications.

About this task

When a user clicks Forgot Password? and provides an email address on the sign-in page, an email is generated with a link where the user can reset the password. When you deploy API Connect, the password-reset settings are configured with default values. You can optionally modify the time-out setting to set a new expiration for resets as well as the notification that is emailed to users.

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Onboarding.
3. Configure the password reset timeout:
   a. In the Settings navigation list, click Onboarding.
   b. Click Edit next to Reset Password Time to Live.
   c. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
   d. Click Save.
4. Customize the notification template for password resets:
   a. In the Settings navigation list, click Notifications.
   b. In the Notifications Templates list, select the appropriate version of the "password-reset" template by clicking the name.
      You can create different versions of the template for different user roles.
   c. Customize the template as explained in Customizing email notification templates.
   d. Click Save.

Results

Password reset notifications contain a link, which expires after the specified the timeout. If the user does not reset the password before the link expires, they can request a new link.

Selecting user registries for Cloud Manager and API Manager

Select the user registries to authenticate users for Cloud Manager and API Manager.

About this task

In Settings > User registries, you select one or more user registries to authenticate users of Cloud Manager and API Manager. The user credentials for all users who login to the applications must be stored in the selected registries.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

For details on how to control which user registries can be used by provider organizations for authenticating Developer Portal users, or for securing APIs, see Setting visibility for a user registry.

Procedure

To select the user registries for Cloud Manager and API Manager, follow these steps:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click User Registries.
3. The current list of user registries is displayed for Cloud Manager and for API Manager. To add user registries, click Edit in either the Cloud Manager or API Manager panel.
   Note: The list of user registries is derived from the user registries that were previously configured as a Resource in Resources > User Registries. For more information, see User registries overview
4. Select the user registry by placing a check mark next to the name in the list. Remove a user registry by removing the check mark.
5. Click Save.

Results

The user registry list is updated to reflect the selected user registries available for authenticating users.

What to do next

To set a user registry as the default, click the options menu next to the registry name in the list, and select Set as default.

- **Setting a default user registry for Cloud Manager and API Manager**
  You can select a default user registry for Cloud Manager and and for API Manager.

Related tasks

- Configuring an LDAP user registry in the Cloud Manager
- Configuring an Authentication URL user registry
- Configuring a Local User Registry

Setting a default user registry for Cloud Manager and API Manager

You can select a default user registry for Cloud Manager and and for API Manager.

About this task

In Settings > User registries, you can set a user registry as the default user registry.

One of the following roles is required to select the user registries for Cloud Manager and API Manager:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` permission

Procedure

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click User Registries.
3. To set a user registry as the default, click the options menu next to the registry name in the list, and select Set as default.
   Note: The list of user registries is derived from the user registries that were previously configured as resources in Resources > User Registries. For more information, see User registries overview

Results

The user registry list is updated to reflect the default user registry.

Related tasks

- Configuring an LDAP user registry in the Cloud Manager
- Configuring an Authentication URL user registry
- Configuring a Local User Registry

Configuring timeouts for access tokens and refresh tokens

Configure timeout values for the access tokens and refresh tokens for user registries.

About this task

IBM® API Connect supports the use of access tokens and refresh tokens for user registries that authenticate users of the Cloud Manager, the API Manager, and the Developer Portal.

Access tokens allow users to sign in and remain logged in for a specified amount of time (the timeout period). Refresh tokens allow the access token to be renewed automatically without requiring the user to sign in again. Access tokens are configured by default, and you can modify the timeout setting. Refresh tokens are disabled by default but are configured with a default timeout when you enable them.

Refresh tokens, when enabled, are generated every time an access token is created. Refresh tokens can be used to obtain a new access token without having to prompt a user to re-login. If you enable the use of refresh tokens, then when the token expires it is refreshed automatically in the background so that the user can continue working without interruption. When the user logs out, the refresh token is revoked and the application can no longer use it.

Note: If users log in with non-OIDC user registries, the use of refresh tokens is supported in API Manager, API Designer, the Developer Portal, and the CLI Toolkit. When the refresh token expires, the user is always redirected to the login page.
If users log in with OIDC user registries:

- If the OIDC providers do not support refresh tokens, API Connect will not issue a refresh_token, regardless of the setting of **`refresh_token_enabled`** in the cloud settings.
- For more information about OIDC configuration, see Configuring an OIDC user registry in Cloud Manager.

You can configure access tokens and refresh tokens using the Cloud Manager UI, or the Toolkit CLI.

Using the UI to configure tokens

Configure timeout settings for access tokens and refresh tokens in the Cloud Manager Settings pages.

Procedure

1. Click  in the navigation pane.
2. Configure the timeout for access tokens:
   a. On the Onboarding page, click Edit next to Access Token Time to Live.
   b. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
   c. Click Save.
3. Configure the timeout for refresh tokens:
   a. On the Onboarding page, click Edit next to Refresh Token Time to Live.
   b. To specify a timeout value, select or type an integer value in the Number field and then choose a unit of time (Seconds, Minutes, or Hours) in the Unit field.
   c. Click Save.

Using the CLI to configure tokens

Use the Toolkit CLI to configure timeout settings for access tokens and refresh tokens.

About this task

Use the following properties to specify refresh tokens for cloud settings:

- **`access_token_expires_in`**
  Integer. Represents the expiration time, in seconds, for access tokens issued by API Connect.
- **`refresh_expires_in`**
  Integer. Represents the expiration time, in seconds, for refresh tokens issued by API Connect. Must be greater than **`access_token_expires_in`**.
- **`refresh_token_enabled`**
  Boolean. Disabled by default. To enable, set to **`true`**. When enabled, generates a **`refresh_token`** field in the response to the **`/token`** API call.

The following extract from a cloud settings file shows example settings for these properties:

```
"type": "cloud_setting",
"api_version": "2.0.0",
"name": "cloud-setting",
"access_token_expires_in": 28800,
.
.
.
"refresh_expires_in": 57600,
"refresh_token_enabled": false,
.
.
.
```

Use the toolkit CLI (**`apic`**) to update the cloud settings with new values for the properties. You can either specify values as command line arguments, or enter them manually in a configuration file as explained in Using the CLI to modify cloud settings.

Viewing platform and UI endpoints

A view-only list of platform and UI endpoints is provided.

About this task

You can view the list of endpoints configured during the installation process. Included in this view-only list are the following endpoints:

- API Manager URL - the URL for opening the API Manager UI
- Platform REST API endpoint for the Admin and Provider REST APIs - this endpoint handles the REST APIs for Admin and Provider functions.
- Platform REST API endpoint for consumer REST APIs - this endpoint handles the REST APIs for consumer (Portal) functions.

One of the following roles is required to view endpoints:

- Administrator
- Owner
- A custom role with the `cloud settings:manage` or `cloud-settings: view` permissions

Procedure

To view the endpoints, follow these steps:

1. In the Cloud Manager, click Settings.
2. Select Endpoints.
3. View the list of endpoints.

Configuring the default gateway services for Catalogs

Configure the list of default gateway services that are available to new Catalogs.

About this task

One of the following roles is required to configure Catalog Defaults:

- Administrator
- Owner
- A custom role with the **`cloud settings:manage`** permission

You publish APIs by adding them to a product and then publishing the product to a catalog. To be able to publish products to a catalog, the catalog must be assigned at least one gateway service so that the APIs in the product are available to be called at a gateway service endpoint. You can assign more than one gateway service to a catalog, and they can be of mixed types, DataPower® API Gateway and DataPower Gateway (v5 compatible).

A product is gateway type specific, either DataPower API Gateway or DataPower Gateway (v5 compatible). By default, when you publish a product to a catalog, it is published to all the assigned gateway services of the same gateway type as the product, but you can choose to publish the product only to selected gateway services, of that type, at publish time; see Publishing a draft product for more information. The APIs in the product will be available to be called at all the specified gateway service endpoints.

The procedure described in this topic specifies the gateway services that are assigned by default to newly created catalogs, but you can change the assigned gateway services for a specific catalog; see Creating and configuring catalogs.

Procedure

To configure the gateway services that are assigned to new Catalogs by default, complete the following steps:

1. In the Cloud Manager, click Settings.
2. In the Settings navigation list, click Catalog Defaults.
3. Click Edit to change the list of default gateway services.
4. Select the required gateway services, then click Save.

Results

When a new Catalog is created in a provider organization, the default gateway services are automatically assigned to it. Any changes you make to the list of default services affects only the Catalogs that are created after you save your changes. Existing Catalogs are not affected.

Managing the public/private key pairs for signing tokens

Manage the public/private key pairs that are used for signing tokens in API Connects.

API Connect uses public-key cryptography to secure tokens. By default, an API Connect deployment receives one public/private key pair, which is used for signing and verifying tokens. When a token is created, API Connect signs it with the deployment's private key. Any third-party can verify that digital signature with the deployment's public key.

The public/private key pair is generated for you by API Connect on the first start-up after installation, upgrade, or migration. The keys are stored in a keystore object.

Why do you need public/private key pairs?

API Connect uses a public/private key pair to sign and verify the following tokens:

- access_token: Verifies that the user has permission to access resources.
- id_token: Stored within the access token to specifies the user's ID.***Confirm?***
- temporary_token: Provides for short-lived access so that the user can log in and receive an access token. For example, when the user receives a link for resetting a password or to register for an account.

How does APIC use the public/private key pair?

Each API Connect deployment is assigned a public key, which is made openly available, plus a corresponding private key, which can only be accessed by that deployment. To verify a user's access to resources for a transaction, API Connect signs every token with the private key. Any other party can use the openly available public key to verify the signature. Because the private key is not shared, it can be used repeatedly instead of generating a new value for each signature.

When your app accesses an API endpoint, the access_token is in JWT format and includes a 'kid" value that is the new key.

Note: The signature for public/private key schema is larger than for shared secrets, so the access_token that is returned will also be larger. If you encounter issues with headers becoming too large, refer to the following topic: Resolving login problems by increasing HTTP header size.

How can you manage public/private key pairs?

By default, your deployment is assigned one key pair, which is stored in a keystore and never expires. The same key pair is used for signing and verify all tokens. The key pair consists of a public key and a private key:

- key_signing: The private key that API Connect uses for signing tokens
- key_verify: The public key that anyone can access and use for verifying token signatures

API Connect uses the following cloud settings to determine which public/private keystores are used for each type of token:

- access_token_keystore_urls: [*keystore_url_0, keystore_url_n*]
- id_token _keystore_urls: [*keystore_url_0, keystore_url_n*]
- temporary_token _keystore_urls: [*keystore_url_0, keystore_url_n*]

Each setting specifies an array of URLs where the keystores are hosted, with the keystore at position 0 representing the current key pair. You can optionally generate additional key pairs, store them in new keystores, and use them with the tokens to enhance security. Each key pair is stored in its own keystore and can be set to expire at a different time. Providing a different key pair for each type of token is a good practice because it limits the damage if a token is compromised.

If you specify one keystore for a token, that key pair is used for every new token of the same type, and it never expires. If you specify multiple keystores, you can assign a lifetime to each and when the keys in the first keystore expire, the keys are obtained from the next keystore in the list, and so on.

You can use the public/private key pairs and keystores to perform the following operations with tokens:

Sign a token
: The first keystore in the array is the current keystore; use its key_signing key to sign tokens.

Verify a token's signature
: To verify a token's signature, start with the current keystore (the first in the array). If the token doesn't match the key_verify key, move to the older keystores and compare the token with the key_verify value in each.

Add key pairs
: When you create a new key pair, add the keys to a separate keystore, and then add that keystore's URL to the end of the token's keystore array. The first keystore in the array is the "current" keystore, and subsequent keystores in the array are used in turn.

Revoke key pairs
: If you suspect that a token is compromised, you can revoke they keys for signing and verifying it. To revoke a key pair, delete the corresponding keystore from the token's keystore array. Removing a keystore removes the keys that were used for signing and verifying tokens, and invalidates all of the tokens that were issued with that key pair.
: Attention: You must always retain at least one key pair for signing and verifying tokens.

Rotate through keystores to periodically change the key pairs in use
: To rotate through key pairs for a token, configure at least two keystores for the token. Specify the "current" keystore first in the array, followed by the "next" keystores. Make sure that the each keystore's lifetime overlaps that of the next keystore so that keys from the current keystore don't expire before the new key pair takes effect.
: Before you configure the lifetime for a keystore, you can refer to the Onboarding section of the Cloud Settings page to quickly see the lifetime that is configured for each type of token. Then make sure you specify enough keystores, with long enough lifetimes, to span each token's lifetime. For example, if the temporary_token lives for 72 hours and the key used for signing it lives for 24 hours, you need to provide at least 3 sets of keys to span the token's lifetime:
:
: temporary_token: [keystore1, keystore2, keystore3]

- **Configuring public/private key pairs for tokens**
  Configure public/private key pairs for signing and verifying tokens in your API Connect deployment.

Configuring public/private key pairs for tokens

Configure public/private key pairs for signing and verifying tokens in your API Connect deployment.

About this task

By default, an API Connect deployment receives one public/private key pair, which is used repeatedly. The public/private key pair is generated for you the first time you start API Connect after installing or upgrading it. The keys are stored in a keystore object. You can add and revoke keys, and configure a rotation through keys for enhanced security.

You can configure key pairs for tokens in the Cloud Manager user interface, or by using the Toolkit CLI.

Using the Cloud Manager UI to configure public/private key pairs

Use the Cloud Manager user interface to configure key pairs for signing and verifying tokens.

About this task

Manage Keystore assignment and Keystore history for tokens

Procedure

1. In the Cloud Manager, click  .
2. In the Settings navigation list, click Signed Token.
   The Signed Token page displays the list of supported tokens for signing.
3. Review the current token settings:
   - Click Payload to display the payload code for the set of tokens.
   - Click History log next to a token to view its previous keystore assignments (this history never includes the current keystore assignment). The most recent assignment displays at the top of the list. You can remove any keystore assignment from the history by clicking  .
4. To add or change a keystore assignment for a token, complete the following steps:
   a. On the Signed Token page, click Edit.
   b. On the Edit signed token page, select a keystore for the token you want to modify.
   c. Click Save to save your changes and update the keystore history.
      Changes take effect immediately.

      The previously selected keystore is added to the history for the token that you just updated. The history never includes the current keystore assignment.

Using the Toolkit CLI to configure public/private key pairs

Use the Toolkit CLI to configure key pairs for signing and verifying tokens.

About this task

Use the following properties to the keystore URLs that contain the public/private key pair for each type of token. For each setting, the list of keystores is an array of strings, with each string representing the complete URL of a keystore. The first keystore in the array (*keystore_url_0*) is the one that is currently in use.

- access_token:

  `access_token_keystore_urls: [keystore_url_0, keystore_url_n]`

- id_token:

  `id_token_keystore_urls: [keystore_url_0, keystore_url_n]`

- temporary_token:

  `temporary_token_keystore_urls: [keystore_url_0, keystore_url_n]`

The keystore URLs can be lengthy. You can avoid errors by writing the settings in a file and uploading that file. Format the settings as a .yaml file (you can choose the file name) and upload the file using the toolkit CLI. The following example configures a different keystore for each type of token:

```
access_token_keystore_urls:
  - >-
    https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/de5298dd-a00b-45a0-9d08-96c5d93e1273
id_token_keystore_urls:
  - >-
    https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/85a21745-8ac3-499d-929a-2d017bade815
temporary_token_keystore_urls:
  - >-
    https://mgmt_endpoint_url/api/orgs/1cdb71a1-b53c-4b66-b162-1b0f45ca8a54/keystores/63d6462f-c93d-439b-b422-0e604381e97a
```

Procedure

1. Create a YAML file with the keystore settings for each type of token as shown in the example.
   For information on using input files with the toolkit CLI, see Reading input from the command line.
2. Run the following command to log in to a management server as a member of the cloud administration organization:

   `apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider`

   Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   `apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm`

   For example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
For more information on logging in, see Logging in to a management server.

3. Upload the YAML file with the new settings by running the following command:

   ```
   apic cloud-settings:update --server mgmt_endpoint_url my_token_keystore_settings.yaml
   ```

4. Run the following command to log out of the management server:

   ```
   apic logout --server mgmt_endpoint_url
   ```

Configuring governance in the Cloud Manager

How to add governance rulesets in the Cloud Manager to validate and enforce organizational governance policies and best practices across your API development process.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. See Enabling governance on Kubernetes, and Enabling governance on VMware for more information. If governance is enabled in your deployment, the Governance icon  is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

The governance service is available to all user roles.

About this task

The governance service is an optional add-on to IBM® API Connect that can be used to validate and enforce organizational governance policies and best practices to your API development process. You configure governance by creating one or more custom rulesets that contain a collection of rules that can then be used to check Swagger, OpenAPI, and AsyncAPI documents, as well as product documents. The governance service contains the following types of rulesets:

API

- Global rulesets - these are custom rulesets that you can keep private, or you can make available to some or all of your provider organizations for validating APIs.
- Default rulesets - these are default rulesets that are built-in to API Connect, and contain pre-configured rules that are available to all of your provider organizations for validating APIs, and cannot be edited.

Product

- Global rulesets - these are custom rulesets that you can keep private, or you can make available to some or all of your provider organizations for validating products.

The governance service is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

Tags can be added to API rulesets that, when matched with the same tag in an API, help ensure that the appropriate rulesets are preselected for your validation scans. In this way, the governance process can be run more quickly and effectively. These preselected rulesets can be deselected from the scan if required.

Note:

- Governance in API Connect supports the creation of custom rulesets that contain rules that use only the built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions. The use of custom functions, for example rules that use functions that you created yourself in JavaScript files, is not supported. Also note that the following Spectral OpenAPI rules aren't supported as they might identify false positives:
  - `oas2-unused-definition`
  - `oas3-unused-component`
- Some of the Spectral rules within the Default rulesets contain the property `recommended: false`, which means that those rules are ignored during validation. However, if you create a new ruleset from one of these rulesets by using the Save as new ruleset option, the `recommended` property isn't transferred to the new ruleset. Therefore, all the rules are used in the validation, unless you delete those rules from the ruleset. The Spectral ruleset names are prefixed with spectral-.
- Dereferencing, which means not introspecting a referenced definition within an API, is not supported in the governance service. Instead, a referenced object can be explicitly validated by using custom rules.
- You can also configure governance rulesets directly in a provider organization. For more information, see Configuring governance in the API Manager.

You can configure both API and product rulesets by using the following methods:

- Create a new ruleset by using the UI
- Import a ruleset
- Create a ruleset by using the CLI

Procedure

- To create a new API or product ruleset by using the Cloud Manager UI, complete the following steps.

1. In the side menu bar, click  Governance.
   The Governance page is displayed.
2. If you want to create an API ruleset, click the API tab. If you want to create a product ruleset, click the Product tab.
   The manage rulesets page is displayed.
3. In the Global rulesets section, click Add > Create from scratch.
   The Create ruleset wizard opens.
4. Provide the following Ruleset info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the ruleset. This name is displayed in the list of global rulesets.	String
Name	Yes	An auto-generated, sluggified, string that is based on the title. It is not editable.	String
Version	Yes	The version number defaults to 1.0.0, but can be edited. You can have rulesets with the same name, but with different version numbers. The version number must be in the format `major.minor.patch`.	String
Description	No	An optional description of the ruleset.	String

5. Optional: For API rulesets, you can add one or more tags to your ruleset by clicking Add, and completing the tag Name and Description.
   Adding matching tags to your rulesets and APIs, means that validation scans can preselect which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags to APIs, see Adding tags to an API.
6. Click Next, and add an initial rule to your ruleset.
7. Provide the following Rule info details.

Property label	Required	Description	Data type
Title	Yes	A short descriptive name for the rule.	String
Name	Yes	An auto-generated, sluggified, string that is based on the title. It is not editable.	String
Description	Yes	A description of the rule.	String
Message	No	Provide a message to help users understand what the goal of the rule is. If no message is provided, the value of the Description property is used for the message output of the validation scan.	String
Severity	Yes	Select a severity level from the following options: • error • warn • info • hint • off error is selected by default.	String

8. In the Given section, specify one or more values for the parts of the API or product document to target. To add more values, click Add. Values must be written in JSONPath.
9. In the Then section, specify the function type and options that will be used to evaluate the target values in the API or product document. Write this section in YAML syntax.
   In the following API rule example, for a Given value of `$` (which means root level of the document), the Then section uses the Spectral core `truthy` function to check that the `info.contact` property value is not `false`, `""`, `0`, `null`, or `undefined`.

   ```
   - field: info.contact
     function: truthy
   ```

   The Then section can also contain a list of functions to be applied to the Given part of the document. In the following API rule example, for a Given value of `$.info.version` (which refers to the `version` property inside the `info` property at the root level of the document), the Then section uses both the `truthy` function, and the Spectral core `pattern` function that checks that the `info.value` matches the regex expression that is given by `functionOptions.match`.

   ```
   - function: truthy
   - function: pattern
     functionOptions:
       match: "^[0-9]+.[0-9]+.[0-9]+(-[a-z0-9+.-]+)?"
   ```

   For a complete list of the Spectral core functions that you can use in your custom API rules, along with examples of these functions, see https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.
10. Click Create to create your draft ruleset.
    Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon .
11. You now have the following options:
    - You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon ⊕ alongside Rules in the navigation pane. Remember to click Save when you finish editing.
    - If you don't want to edit your ruleset further now, click Governance in the breadcrumb trail to return to the Governance overview page.

- To import an existing API or product ruleset, complete the following steps. Remember that for API rulesets, the rules in your imported ruleset can contain only built-in Spectral core functions, as defined in https://docs.stoplight.io/docs/spectral/cb95cf0d26b83-core-functions.

  1. In the side menu bar, click  Governance.
     The Governance page is displayed.
  2. If you want to create an API ruleset, click the API tab. If you want to create a product ruleset, click the Product tab.
     The manage rulesets page is displayed.
  3. In the Global rulesets section, click Add > Import.
     The Import ruleset wizard opens.
  4. Drag a file into the Upload file box, or click in the Upload file box to select a file to upload. The maximum file size is 100 kb, and the supported file types are YAML, YML, and JSON.
  5. Click Next.
  6. Edit the Ruleset info details as required, and click Import.
     Your draft ruleset opens in design form view. Note that you can switch to the OpenAPI YAML source view by clicking the Source icon </>. To return to the design form view, click the Form icon  .
  7. You now have the following options:

- You can continue to edit your ruleset. For example, you can add more rules by clicking the Create rule icon alongside Rules in the navigation pane. Remember to click Save when you finish editing.
- If you don't want to edit your ruleset further now, click Governance in the breadcrumb trail to return to the Governance overview page.

- To create an API or product ruleset by using the toolkit CLI, complete the following steps.
  1. Create a JSON file that contains the new ruleset.
     The following JSON shows the contents of an example API document ruleset file:

```
{
    "name": "short-draft-ootb",
    "title": "short-draft-ootb",
    "description": "short ruleset",
    "ruleset_type": "global-custom",
    "tags": [
      {
        "name": "general",
        "description": "general work"
      }
    ]
    "rules": [
      {
        "name": "sec-array-boundaries-2",
        "description": "Array size should be limited to mitigate resource exhaustion attacks.\nThis can be done using
`maxItems` and `minItems`, like in the example\nbelow.\n\n```\nLimited:\n  type: array\n  maxItems: 10\n  items:\n
type: string\n    format: date\n```\n\nYou should ensure that the schema referenced in  `items` is constrained
too.\n\nIf you delegate input validation to a library or framework,\nbe sure to test it thoroughly and ensure that it
verifies `maxItems`.",
        "message": "Schema of type array must specify maxItems and minItems. {{path}} {{error}}",
        "formats": [
          "oas3"
        ],
        "severity": "warn",
        "recommended": true,
        "given": [
          "$..[?(@.type==\"array\")]"
        ],
        "then": [
          {
            "field": "maxItems",
            "function": "defined"
          }
        ]
      }
    ]
  }
```

     The following JSON shows the contents of an example product document ruleset file:

```
{
  "type": "ruleset",
  "ruleset_type": "custom",
  "api_version": "2.0.0",
  "id": "dbb5f400-e707-412e-b081-ac36f5afbbb9",
  "name": "test-product",
  "title": "Test Product",
  "description": "",
  "ruleset_version": "1.0.0",
  "ruleset_state": "draft",
  "ruleset_format_type": "2",
  "rule_urls": [
    "https://my.manager.com/governance/orgs/myorg/rulesets/1.0.0-test-product/rules/ca6ef7d9-a503-498e-8f53-
4e3aa35d086b"
  ],
  "created_at": "2024-05-22T17:19:02.820Z",
  "updated_at": "2024-05-22T17:24:59.000Z",
  "url": "https://my.manager.com/governance/orgs/myorg/rulesets/dbb5f400-e707-412e-b081-ac36f5afbbb9",
  "rules": [
    {
      "api_version": "2.0.0",
      "id": "ca6ef7d9-a503-498e-8f53-4e3aa35d086b",
      "name": "subscribe",
      "version": "1.0.0",
      "title": "subscribe",
      "description": "subscribe enabled",
      "message": "subscribe not enabled",
      "given": [
        "$.visibility.subscribe.enabled"
      ],
      "severity": "error",
      "created_at": "2024-05-22T17:19:02.000Z",
      "updated_at": "2024-05-22T17:24:59.000Z",
      "url": "https://my.manager.com/governance/orgs/myorg/rulesets/1.0.0-test-product/rules/ca6ef7d9-a503-498e-8f53-
4e3aa35d086b",
      "then": [
        {
          "function": "pattern",
          "functionOptions": {
            "notMatch": "/true"
          }
        }
      ]
    }
  ]
}
```

2. Log in to the toolkit as an Admin.
   For example:

   ```
   apic login --server mgmt_endpoint_url --username admin --password password --realm admin/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For full details of the `apic login` command, see Logging in to a management server.

3. Run the `rulesets:create` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:create --org <target_org> --server <server_url> RULESET_FILE
   ```

   Where:
   - `<target_org>` is the name of the organization that owns the new ruleset.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `RULESET_FILE` is the path and file name of the JSON file that contains the ruleset.

Results

Your draft API or product ruleset is now listed in the table of Global rulesets.

What to do next

When you finish editing your ruleset, you can publish it to your provider organizations. Click the options menu icon ⋮ either next to the ruleset that you want to publish, or from within the ruleset viewer. Select Publish, and then click Publish again to confirm. The status of your ruleset changes from Draft to Published, and can now be used to validate API and product documents. For more information, see Validating an API document by using governance.

You can also use a published ruleset to validate an API or product document in the Cloud Manager. Click Validate, upload a document file to validate, and then select the rulesets and rules that you want to use for the validation. If the API that you want to validate includes a tag that has a matching tag in one or more rulesets, then those rulesets are automatically selected for the scan. However, you can edit the ruleset selection to your requirements. The results of the validation are displayed in a scorecard.

Note:

- After a ruleset is published, the ruleset information and rules can no longer be edited. If you need to update this information, you must create a new version by clicking the options menu icon ⋮ either next to the ruleset that you want to edit, or from within the ruleset viewer, and selecting Save as new ruleset.
- By default, rulesets are published to all of your provider organizations. If you want to change which provider organizations can use your rulesets, you must edit the visibility after publishing.

If you want to change the visibility of your ruleset, click the options menu icon ⋮ either next to the ruleset that you want to edit, or from within the ruleset viewer. Then click Edit visibility, and select from the following visibility options:

- Private - the ruleset is not visible and cannot be used by any provider organization.
- Public - the ruleset is visible and can be used by all provider organizations.
- Custom - the ruleset is visible to and can be used by only the provider organizations that are designated by you.

Click Save to confirm your visibility option.

- **The governance ruleset lifecycle in the Cloud Manager**
  When you manage your custom governance rulesets in the Cloud Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.
- **Updating rulesets and rules with the toolkit CLI**
  Use the API Connect toolkit CLI to update a ruleset or individual rules.

The governance ruleset lifecycle in the Cloud Manager

When you manage your custom governance rulesets in the Cloud Manager UI, you move them through a series of lifecycle states. From initially creating a draft ruleset, through to publishing to make the ruleset available to your API developers, to creating new versions, and to eventual archiving.

The following sections describe the various lifecycle states for a custom governance ruleset.

Note:

- Approval is not required for any of the lifecycle state transitions.
- Default rulesets are built-in to API Connect, and contain pre-configured rules that are available to all of your provider organizations, and cannot be edited. These rulesets are always in the Published state, and their visibility cannot be changed.

Draft

The draft state for a ruleset is when the ruleset is not published, and isn't visible any provider organization. The ruleset can continue to be edited, and its Status is shown as Draft.

Published

When you publish a ruleset, it is made visible to all of your provider organizations, and cannot be changed. The ruleset Status is shown as Published, and the ruleset visibility is shown as Public. If you want to change which provider organizations can use your rulesets, you must edit the visibility after publishing. You can select from the following visibility options:

- Private - the ruleset is not visible and cannot be used by any provider organization.
- Public - the ruleset is visible and can be used by all provider organizations.
- Custom - the ruleset is visible to and can be used by only the provider organizations that are designated by you.

Any other changes require a new version of the ruleset to be created by using the Save as new ruleset option.

Archived

When you archive a ruleset, it becomes a ready-only, fixed version of the ruleset that cannot be used for validation by any provider organization. The ruleset Status is shown as Archived.
Note: If you cannot see your Archived ruleset, ensure that the Edit filters option on the ruleset table is set to include Archived.
You can restore archived rulesets by using the Restore option, after which the Status returns to Published.

Also, you can delete Archived rulesets by using the Delete option.

Updating rulesets and rules with the toolkit CLI

Use the API Connect toolkit CLI to update a ruleset or individual rules.

Updating a ruleset

1. Create a JSON file that defines the updated ruleset.
   The following example shows an updated ruleset:

   ```
   {
       "title": "custom-ruleset-2",
       "description": "short ruleset updated",
       "ruleset_type": "custom"
   }
   ```

   where:
   - `title` is updated to a new title for the ruleset.
   - `description` is updated to a new description for the ruleset.
   - `ruleset_type` is updated to be custom for the ruleset.
2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the ruleset.
3. Run the `rulesets:update` toolkit command in `governance` mode:

   ```
   apic -m governance rulesets:update --org <target_org> --server <server_url> RULESET RULESET_FILE
   ```

   where:
   - `<target_org>` is the name of the organization that owns the ruleset.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `RULESET_FILE` is the path and filename of the JSON file that contains the updated ruleset.
   - `RULESET` is the name or the unique ID of the updated ruleset.
     To determine the ID of a ruleset, run the following command:

     ```
     apic -m governance rulesets:list --org <target_org> --server <server_url>
     ```

Updating a rule

1. Create a JSON file that defines the updated rule.
   The following example shows an updated rule in a file called:

   ```
   {
     "description": "Updated the rule",
     "message": "Schema of type array must specify maxItems and minItems. {{path}} {{error}}",
     "formats": [
       "oas3"
     ],
     "severity": "warn",
     "recommended": true,
   ```

```
  "given": [
    "$..[?(@.type==\"array\")]"
  ]
}
```

where:

- `description` is updated to a new title for the rule
- `message` is updated to a new message for the rule
- `formats` array is replaced to have only the format oas3 for the rule
- `severity` is updated to the warn value for the rule
- `recommended` is updated to have a new value for the rule
- `given` array is replaced to have new values for the rule

2. Log in to the toolkit as an Admin or as the owner of the provider organization that owns the rule.
3. Run the `rules:update` toolkit command in `governance` mode.
   There are two ways to specify the updated rule in the command, depending on whether you provide the rule name and version, or the rule ID:

   Specify the rule name and version in the update command

   ```
   apic -m governance rules:update --org <target_org> --server <server_url> --ruleset <ruleset_name or ruleset_id>
   NAME:VERSION RULE_FILE
   ```

   where:

   - `<target_org>` is the name of the organization that owns the rule.
   - `<server_url>` is the management server URL that you use for logging in to the toolkit.
   - `<ruleset_name or ruleset_id>` is the name or the unique ID of the ruleset to which the updated rule belongs.
   - `NAME` is the name of the updated rule.
   - `VERSION` is the version of the updated rule; increase the version when you update the rule, using the `major.minor.patch` format as in "1.0.1".
   - `RULE_FILE` is the path and filename of the JSON file that contains the updated rule.

   Specify the rule ID in the update command

   Instead of providing the rule's name and version, you can provide its unique ID instead by running the following command:

   ```
   apic -m governance rules:update --org <target_org> --server <server_url> --ruleset <ruleset_name or ruleset_id> --id
   <rule_id> RULE_FILE
   ```

   where:

   - `<target_org>` is the name of the organization that owns the rule.
   - `<server_url>` is the management server URL that you specified when you logged in to the toolkit.
   - `<ruleset_name or ruleset_id>` is the name or the unique ID of the ruleset to which the update rule belongs.
   - `RULE_FILE` is the path and filename of the JSON file that contains the updated rule.
   - `<rule_id>` is the value of the updated rule's unique ID.
     To determine the ID of a rule, run the following command:

     ```
     apic -m governance rules:list --org <target_org> --server <server_url> --ruleset <ruleset_name> RULE_NAME
     ```

Administering provider organizations

Manage the provider organizations who have accounts to publish APIs in your API Connect cloud.

About this task

Perform these tasks to manage your provider organizations:

- **Creating a provider organization**
  For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.
- **Editing a provider organization**
  You can edit the title of a provider organization, and also transfer ownership to a new organization owner.
- **Deleting a provider organization**
  You can delete a provider organization. All Catalogs and Spaces are also removed.
- **Viewing current provider organizations**
  View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.
- **Sending messages to provider organization owners**
  You can send an email message to the owner of a provider organization. You can also style the email to match your business theme.

Related tasks

- Creating a provider organization
- Editing a provider organization
- Deleting a provider organization
- Viewing current provider organizations

Creating a provider organization

For developers to publish APIs, they must be a member of a provider organization. The first step is to create a provider organization and specify an organization owner. Then members can be added to the provider organization and can start publishing APIs.

Before you begin

This task can be completed by users who are assigned one of the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

You must also complete the following tasks before beginning:

- Configuring an email server for notifications
- Setting up notifications

About this task

Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

There are two options for creating a provider organization account, as follows:

- Option 1: Create a provider organization and send an email invitation to a new user to register and become the organization owner. Choose the Add > Invite organization owner option.
- Option 2: Create a provider organization and specify the user who will be the organization owner. Choose the Add > Create organization option.

Procedure

- **Option 1:** To create a provider organization and invite a new user to register as the owner, complete the following steps:
  1. In the Cloud Manager, click  Provider Organizations.
  2. Click Add > Invite organization owner
  3. Enter a valid email address and click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Get Activation Link and click Copy in the pop up window. Note that the email server requires the Authenticate User and Authenticate Password values in order to send invitations. See Configuring an email server for notifications.

     The new provider organization is placed in Pending status, and is changed to Enabled status after the owner completes the registration form to activate their account. The owner can then log in to the API Manager user interface with the API Connect user name that they specified during account activation.

     Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously provider organization owners but whose organization was deleted.
- **Option 2:** To create a provider organization and specify the user who will be the organization owner, complete the followings steps:
  1. In the Cloud Manager, click  Provider Organizations.
  2. Click Add > Create organization.
  3. In the Title field, enter a title for the provider organization. If desired, the title can be edited after the provider organization is created.
  4. The internal Name is automatically generated for you by the system. The Name field contains the string that is included in the organization segment of the URL for API calls. For more information, see Calling an API.
     Tip: The Name field is auto-generated to ensure its validity in the URL.
     The value in the Name field is also used to identify the provider organization in developer toolkit CLI commands. To view the CLI commands to manage provider organizations, see the toolkit CLI reference documentation.

  5. Select the user registry for the provider organization owner.
     The remaining procedure varies according to the type of the selected user registry, as follows:
     - Local User Registry
       - Select whether the user is an Existing user or a New User.
         - For an existing user, complete the following steps:
           - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
           - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
         - For a new user, complete the following steps:
           - Enter a unique user name for the new user.
           - Supply an email address, name details, and a password.
           - Click Create. The user account is created, and the provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with the specified user name and password; the user interface open in the new provider organization.
     - LDAP
       - Enter the name of a user that exists in the selected user registry.
       - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface with their LDAP user name. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.
     - Authentication URL and OIDC
       - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must use the invitation mechanism described in Option 1.
       - Click Create. The provider organization is created and immediately enabled. The specified owner can log in to the API Manager user interface. If the new provider organization is the user's only provider organization, the API Manager user interface opens in that provider organization; if the user is a member of more than one provider organization, they can then select the new provider organization from the Organization list.

What to do next

For details of how an invited organization owner activates their account see Activating your API Manager user account. For details of how to log in to the API Manager user interface, see Accessing the API Manager user interface.

Editing a provider organization

You can edit the title of a provider organization, and also transfer ownership to a new organization owner.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

About this task

If you transfer ownership, the new organization owner can be an existing user, or you can create a new user. When the ownership changes, the new owner is assigned administration privileges for the organization, and the previous owner has their administration privileges removed. Optionally, you can also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner. If required, you can restore the privileges to the previous owner as described in Administering members and roles.

Procedure

To update a provider organization, complete the following tasks:

1. In the Cloud Manager, click  Provider Organizations.
2. Click the name of the provider organization that you want to update.
3. To change the title, enter a new title in the Title field, then click Save.
4. To transfer ownership, select the user registry for the provider organization owner you want to transfer ownership to.
   The remaining procedure varies according to the type of the selected user registry, as follows:
   - Local User Registry
     - Select whether the user is an Existing user or a New User.
       - For an existing user, complete the following steps:
         - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
         - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
         - Click Save.
       - For a new user, complete the following steps:
         - Enter a unique user name for the new user.
         - Supply an email address, name details, and a password.
         - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
         - Click Save.
   - LDAP
     - Enter the name of a user that exists in the selected user registry.
     - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
     - Click Save.
   - Authentication URL and OIDC
     - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account. If the required organization owner has not previously been invited and activated their account, you must ensure they have been invited to the organization first.
     - To also have the ownership of all Catalogs and Spaces in the organization transferred to the new organization owner, select Also transfer ownership of owned Catalogs and Spaces.
     - Click Save.

Deleting a provider organization

You can delete a provider organization. All Catalogs and Spaces are also removed.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner
- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

About this task

The user account for the owner of the deleted provider organization remains in the associated API Connect user registry. The user can still log in to the API Manager user interface; if they are a member of one or more other provider organizations then those organizations are accessible, otherwise only information links are available, with no access to view or manage any resources.
The user can be added again as a provider organization owner at a later time; see Creating a provider organization.

Procedure

To delete a provider organization, complete the following tasks:

1. In the Cloud Manager, click  Provider Organizations.
2. Navigate to the provider organization that you want to delete in the list and select Delete from the Actions menu.
3. Confirm that you want to delete the provider organization.
   The provider organization is deleted and removed from the Provider Organizations list.

Results

The provider organization, and its Catalogs and Spaces, are deleted.

Viewing current provider organizations

View the list of current provider organizations for your cloud, including organization title, owner's name and email address, and status. From the list screen, you can add new provider organizations and owners, edit and delete provider organizations, send messages, and change owners.

Before you begin

You must also complete the following tasks before beginning:

- Configuring an email server for notifications
- Setting up notifications
- Creating a provider organization

This task can be completed by users who are assigned one of the following roles:

- All roles
- Custom role with the `Provider-org:Manage` or the `Provider-org:View` permissions

About this task

All roles can view the list of provider organizations. Use the provider organization list screen to manage your provider organizations.

Procedure

1. In the Cloud Manager, click  Provider Organizations.
2. View the list of provider organizations and their status. The statuses are as follows:
   - **Pending**: A provider organization is in `Pending` status until the invited owner successfully completes the registration form.
   - **Enabled**: A provider organization is in `Enabled` status if the owner is an existing user with an account in a user registry.
3. The Actions menu performs different functions depending on the organization's status.
   - For an Enabled organization, you can Edit or Delete the organization or you can send a message to the provider organization owner by clicking Message owner.
   - For a Pending organization, you can resend the invitation by clicking Resend invite, or Delete the request.
4. Add new provider organizations using the Add menu. See Creating a provider organization

Related tasks

- Creating a provider organization
- Editing a provider organization
- Deleting a provider organization

Sending messages to provider organization owners

You can send an email message to the owner of a provider organization. You can also style the email to match your business theme.

Before you begin

This task can be completed by users who are assigned the following roles:

- Cloud Owner

- Cloud Administrator
- Organization Manager
- Custom role with the `Provider-org:Manage` permission

Note: You can also send email messages by using the developer toolkit CLI, or by using the API Connect REST APIs. See Cloud administration commands, or API Connect REST APIs, for more information.

Procedure

To send a message, complete the following steps:

1. In the Cloud Manager, click Provider Organizations.
2. Click the options icon ⋮ alongside the provider organization that you want to work with, then click Message owner.
   The Send message window opens, and the email address of the provider organization owner is displayed as the recipient.
3. Enter the subject of the message in the Subject field.
4. Select the Content type that you want to use for the entering the content of the message, from HTML, PlainText, or Both. The default content type is PlainText.
   An edit window for the selected content type is displayed, or both edit windows are displayed if Both is selected.
   For HTML content, only the tags and their attributes that are shown in the following table are allowed.

   Table 1. List of allowed HTML tags and their attributes

HTML tag	Attribute
`<a>`	`"class", "href", "hreflang", "style"`
`<em>`	`"class", "style"`
`<strong>`	`"class", "style"`
`<cite>`	`"class", "style"`
`<blockquote>`	`"class", "cite", "style"`
`<code>`	`"class", "style"`
`<ul>`	`"class", "type", "style"`
`<ol>`	`"class", "start", "type", "style"`
`<li>`	`"class", "style"`
`<dl>`	`"class", "style"`
`<dt>`	`"class", "style"`
`<dd>`	`"class", "style"`
`<h1>`	`"class", "id", "style"`
`<h2>`	`"class", "id", "style"`
`<h3>`	`"class", "id", "style"`
`<h4>`	`"class", "id", "style"`
`<h5>`	`"class", "id", "style"`
`<h6>`	`"class", "id", "style"`
`<p>`	`"class", "style"`
`<div>`	`"class", "style"`
` `	`"class", "style"`
`<span>`	`"class", "style"`
`<img>`	`"class", "src", "alt", "data-entity-type", "data-entity-uuid", "data-align", "data-caption", "width", "height", "style"`
`<table>`	`"class", "id", "style"`
`<tr>`	`"class", "id", "style"`
`<td>`	`"class", "id", "style"`

   If an HTML tag that is not allowed is used in a notification, the tag and its contents are displayed in the email as plain text.
   Images can be used by adding a **`<img src="https://path/to/image.png"/>`** tag in the template. The **`src`** attribute for the image must be a fully qualified web URL, and must be externally accessible so that the email recipients can access the image. It's not possible to reference local images, they must be fully qualified URLs. It's also not possible to embed or attach images or other files in the emails.
5. Enter the content of the message.
6. Click Send.

Administering members and roles

Cloud Administrators can add members and assign them roles to enable them to work in Cloud Manager. The Cloud and Topology Administrators can also create roles and role defaults. You can also delete users to prevent them from accessing Cloud Manager.

About this task

To manage roles, add members, and assign roles to member, perform the following tasks:

- **Creating roles in the admin organization**
  Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.
- **Editing roles in the admin organization**
  As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.
- **Configuring LDAP group mappings on Cloud Manager user roles**
  As a Cloud Manager administrator, you can configure LDAP group mapping on API Connect roles in the Admin organization by using the developer toolkit CLI.
- **Deleting roles in the admin organization**
  Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.

- **Viewing members and roles**
  Use the Members page to view the current members of the Admin organization and manage the role assignments.
- **Adding members to the admin organization**
  As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.
- **Assigning roles to members**
  As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.
- **Deleting a member**
  As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.
- **Role Defaults overview**
  Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Creating roles in the admin organization

Cloud Manager ships with a set of pre-configured roles. As the Cloud Manager administrator, you can create custom roles, add permissions, and assign the roles to members of the Admin organization.

About this task

If you are assigned a role that has the `Settings: manage` permission, you can create custom roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.
One of the following roles is required to add custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Procedure

Perform the following steps to add custom roles to the Admin Organization:

1. In the Cloud Manager, click  Settings.
2. Select Roles.
3. Click Add to add a new role.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the custom role.

Results

The custom role appears in the list of roles and can be assigned to members.

What to do next

Assign the role to a member in the Members list. See Assigning roles to members

Related tasks

- Editing roles in the admin organization

Editing roles in the admin organization

As the Cloud Manager administrator, you can edit the roles in the Admin Organization. Both pre-configured roles and custom roles may be edited, except for the Owner, Viewer, and Member roles. The Owner, Viewer, and Member roles may not be edited or deleted.

About this task

You can customize the per-configured roles (except for the Owner, Viewer, and Member roles) to reflect your business needs.

If you are assigned a role that has the `Settings: manage` permission, you can edit the roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.

One of the following roles is required to edit roles:

- Administrator
- Owner

- Topology Administrator
- Custom role with the `Settings: manage` permissions

Following are the edits you can perform for a role:

- Change the title
- Add or delete permissions

Procedure

Perform the following steps to edit roles in the Admin organization:

1. In the Cloud Manager, click Settings.
2. Select Roles.
3. Locate the Role you want to edit, and select Edit from the overflow menu.
4. Enter the desired Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the updated role.

Results

The Role will be updated with a new name and/or permissions. An updated role will affect the members who are assigned the role. If you change the name of a role, you will have to assign it to the members. If you change the permissions for a role, the way that members use the product may change.

Configuring LDAP group mappings on Cloud Manager user roles

As a Cloud Manager administrator, you can configure LDAP group mapping on API Connect roles in the Admin organization by using the developer toolkit CLI.

Before you begin

You must have an LDAP user registry resource in the Cloud Manager that has the **`external_group_mapping_enabled`** configuration set to **`true`**. See Using the CLI to configure a shared LDAP user registry for information.

One of the following roles is required to edit roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Note: The Admin organization roles apply only to Cloud Manager users. If you want to apply LDAP group mapping to API Manager users, see Configuring LDAP group mapping on API Manager user roles. LDAP group mapping cannot be applied to Developer Portal users.

About this task

You can map external LDAP groups to the API Connect preconfigured user roles (except for the Owner and Member roles), as well as to any custom user roles, to reflect your business needs.

Notes:

- After LDAP group mapping is enabled on a role, user onboarding always honors the group mappings.
- Once on-boarded, user membership in API Connect is valid throughout the login period (**`access_token_ttl`**), irrespective of any changes in the external LDAP registry. Membership is updated only on the next login, when the LDAP information is fetched and refreshed.
- One or more API Connect roles can be mapped to one or more LDAP groups, and one or more LDAP groups can be mapped to a role.
- When multiple LDAP groups are mapped to a single role, it means that a user from any one of the LDAP groups can log in to API Connect.
- If a user is removed from the external LDAP user registry, then to ensure quick removal from API Connect you must also delete the user membership in API Connect.

You can configure LDAP group mappings using one of the following methods:

- Using the UI to configure LDAP group mappings
- Using the CLI to configure LDAP group mappings

Using the UI to configure LDAP group mappings

Use the Cloud Manager UI to configure LDAP group mappings.

Procedure

1. Login to the Cloud Manager UI as a user with the appropriate permissions.
2. Click Settings > Roles > Add a new Role or edit existing role .
3. Select the following settings:
   - Enable external group mapping - select to enable external group mapping for this role.
   - LDAP user Registry - LDAP user registry list which has external group mapping enabled. User must select one of the LDAP user registry from this list.
   - LDAP group names - add one or more LDAP group names that you want to map to the user role.

- User group prefix - add the prefix for the LDAP user group.
- User group suffix - add the suffix for the LDAP user group.

4. Save your changes.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the Cloud Manager, and automatically be assigned the correct access permissions for their role.

Using the CLI to configure LDAP group mappings

Use the toolkit CLI to configure LDAP group mappings.

About this task

For detailed information about how to use the CLI, see Installing the toolkit, and Overview of the command-line tool.

Procedure

Perform the following steps to map external LDAP groups to Cloud Manager user roles.

1. Log in to the management server CLI.
   Before you can update the role configuration, you must log in to your management server from the developer toolkit CLI as a member of the cloud administration organization. Use the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   where ***mgmt_endpoint_url*** is the platform API endpoint URL.
   You can determine which identity provider to use in the **--realm** parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The **title** value should enable you to determine which identity provider to use; you can then copy the corresponding **--realm** parameter directly from the displayed **realm** value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is **default-idp-1**.
   For full details of the login command, see Logging in to a management server.

2. Run the following command to get the URL of the LDAP user registry resource in the Cloud Manager that you want to map the user roles to:

   ```
   apic user-registries:get  ldap_user_registry --org admin --server mgmt_endpoint_url --output -
   ```

   where:
   - ***ldap_user_registry*** is the name or ID of your LDAP user registry resource.
   - **--org admin** means that the registry details are retrieved from the admin organization.
   - ***mgmt_endpoint_url*** is the platform API endpoint URL.

   This command outputs the configuration details of your LDAP user registry, and the **url:** is shown at the end of the list, for example:

   ```
   type: user_registry
   api_version: 2.0.0
   id: 35e75bad-1d89-4a65-a70f-xxxxxx
   name: ldap
   title: LDAP
   integration_url: >-
     https://server.com/api/cloud/integrations/user-registry/147b5fb1-e88e-41e3-90e9-xxxxxx
   registry_type: ldap
   user_managed: false
   user_registry_managed: false
   external_group_mapping_enabled: true
   ...
   url: >-
     https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
   ```

3. Create a role yaml file that contains the following LDAP group mapping configuration properties:

   ```
   external_group_mapping:
     user_registry_url: https://server.com/api/user-registries/3d58ce7e-16a8-493b-9684-xxxxxx/35e75bad-1d89-4a65-a70f-xxxxxx
     ldap_groups:
       - 'cn=apic-administrators,ou=ibmgroups,o=ibm.com'
       - 'cn=apic-developers,ou=ibmgroups,o=ibm.com'
     user_group_filter_prefix: (&(uniquemember=
     user_group_filter_suffix: )(objectClass=groupOfUniqueNames))
   ```

   Where:
   - **user_registry_url** is the URL of your LDAP user registry resource from Step 2.
   - **ldap_groups** is a list of the LDAP group names that you want to map to the user role.
   - **user_group_filter_prefix** is the prefix for the LDAP user group.
   - **user_group_filter_suffix** is the suffix for the LDAP user group.

4. Run the following command to update the user role with the **external_group_mapping** configuration properties:

```
apic roles:update role_name --scope org --org admin --server mgmt_endpoint_url mapping_properties_file
```

Where:

- ***role_name*** is the name of the user role that you want to add the LDAP group mapping to.
- **--scope** is the organization scope that you want the update to apply to. For this task, the value must be **org**.
- **--org admin** means that the user role is updated on the admin organization.
- ***mgmt_endpoint_url*** is the platform API endpoint URL.
- ***mapping_properties_file*** is the name of your mapping properties file from Step 3, for example **role_mapping_file.yaml**.

If you prefer to enter the configuration properties interactively on the command line, you can substitute the ***mapping_properties_file*** for a terminating hyphen character **-**, and enter the information manually, followed by pressing **CTRL D** to terminate the input.
If you want to create a custom role that includes LDAP group mapping, you can include the **external_group_mapping** configuration section in the **role_file**, and then create the new role by using the **apic roles:create** command.

For more information about the **apic roles** commands, see the toolkit CLI reference documentation.

Results

The role is updated with the LDAP group mapping information. Users can now log on to the Cloud Manager, and automatically be assigned the correct access permissions for their role.

Deleting roles in the admin organization

Roles can be deleted (except for the Owner, Viewer, and Member roles) from the Admin organization. If there are members assigned to a role that has been deleted, they will be assigned the Viewer role.

About this task

All custom roles may be deleted. Pre-configured roles can also be deleted, except for the Owner, Viewer, and Member roles. Owner, viewer, and Member role cannot be deleted or edited. Members who are assigned a deleted role are given the most limited role, Viewer, with View-only privileges. These members will need to be assigned a new role if they require any other privileges.

If you are assigned a role that has the `Settings: manage` permission, you can delete roles for the Admin organization. The Admin organization roles apply only to Cloud Manager users.
One of the following roles is required to delete custom roles:

- Administrator
- Owner
- Topology Administrator
- Custom role with the `Settings: manage` permissions

Procedure

Perform the following steps to delete roles in the Admin organization:

1. In the Cloud Manager, click Settings.
2. Select Roles.
3. Locate the Role you want to delete, and select Delete from the overflow menu.
4. Confirm that you want to proceed with deleting the role.

Results

The Role will be deleted. Members who had been assigned the role are given the Viewer role.

Viewing members and roles

Use the Members page to view the current members of the Admin organization and manage the role assignments.

Procedure

To view the members of the Admin organization and their roles in Cloud Manager, follow these steps:

1. In the Cloud Manager, click Members.
2. From the Members list, you can scroll through the list of users to see their current roles and their status.
   - **Pending** - The invitation with the activation link has been sent to the user, but they have not yet completed the registration form.
   - **Enabled** - The user has completed the registration form and is now able to login and access the features associated with their role.

   Note: If your role has the proper permissions, you can assign roles, add, and delete members from this list.

What to do next

- To add members, see Adding members to the admin organization

- To change the roles assigned to members see Assigning roles to members
- To delete a member, see Deleting a member

Adding members to the admin organization

As the Cloud Manager administrator, you can add and remove members of the Admin organization and assign roles to them. Once removed, a user can no longer access the Cloud Manager.

About this task

Membership in the Admin organization is required to use Cloud Manager to view and manage the topology of the API Connect cloud, to set up and manage provider organizations, and to manage other features of the cloud. There are two ways to add a member:

- Invite member - send an email invitation to a new user to register as a member of the Admin organization.
- Add member - specify the user and add them as a member of the Admin organization immediately.

One of the following roles is required to add members:

- Administrator
- Owner

Procedure

- To send an email invitation to a new user to register as a member of the Admin organization, complete the following steps:
  1. In the Cloud Manager, click  Members.
     The list of current members for the Admin organization is displayed. You can view the owner of the Admin Organization by expanding View Owners.
  2. Click Add > Invite member.
  3. Enter a valid email address.
  4. Select the roles that you want to assign to the user.
  5. Click Invite. An email containing an activation link is sent to the email address inviting the person to register. The link opens the registration form. Alternately, you can copy and paste the activation link into an email; click Get Activation Link and click Copy in the pop up window.
     Note that the email server requires the Authenticate User and Authenticate Password values in order to send invitations. See Configuring an email server for notifications.

     The user is placed in Pending status, and is changed to Enabled status after they complete the registration form to activate their account. They can then log in to the Cloud Manager user interface with the API Connect user name that they specified during account activation.
     Note: If you use this option with a Local User Registry, and the user already exists in the registry, the user must re-activate their account by using the Sign In option, **not** by completing the registration form and using the Sign Up option; attempting to re-register will fail. This stipulation includes users that were previously members but were deleted from the admin organization.
- To specify the user and add them as a member of the Admin organization immediately, complete the following steps:
  1. In the Cloud Manager, click  Members.
     The list of current members for the Admin organization is displayed. You can view the owner of the Admin Organization by expanding View Owners.
  2. Click Add > Add member.
  3. Select the required user registry
     The remaining procedure varies according to the type of the selected user registry, as follows:
     - Local User Registry
       - Select whether the user is an Existing user or a New User.
         - For an existing user, complete the following steps:
           - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
           - Select the roles that you want to assign to the user, then click Add. The user is added and their membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
         - For a new user, complete the following steps:
           - Enter a unique user name for the new user.
           - Supply an email address, name details, and a password.
           - Select the roles that you want to assign to the user, then click Add. The user account is created, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.
     - LDAP
       - Enter the name of a user that exists in the selected user registry.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface with their LDAP user name.
     - Authentication URL and OIDC
       - Enter the name of an existing API Connect user that has previously been invited to register and has activated their account.
       - Select the roles that you want to assign to the user, then click Add. The user is added, and the user membership is immediately enabled. The specified user can log in to the Cloud Manager user interface.

What to do next

The new member can log in and work in Cloud Manager. The member's authorization is defined by the roles assigned to them.
For instructions on assigning roles, see Assigning roles to members. The list of roles and permissions can be viewed at User roles and permissions in the Cloud Manager UI.

Assigning roles to members

As the Cloud Manager administrator, you manage the roles that are assigned to members. A member's role determines the tasks they are authorized to perform in Cloud Manager.

About this task

Members in the Admin organization use Cloud Manager to view and manage the topology of the Cloud, to set up and manage provider organizations, and to work with other features of the API Connect Cloud. The member's role determines what tasks they are authorized to perform.
When assigning roles, you need to be aware that all members always have a basic set of permissions, which are contained in the **Member** role. The Member role is automatically granted to all members and cannot be removed. For this reason, you do not explicitly assign the Member role. You can grant additional permissions by selecting one or more roles. If additional roles are not assigned, then the user will have only the basic Member role.

One of the following roles is required to assign roles to members:

- Administrator
- Owner

Procedure

Perform the following steps to assign one or more roles to a member:

1. In the Cloud Manager, click  Members.
2. The list of current members for the Admin organization is displayed.
3. To change the roles assigned to a member, select the roles by marking the check boxes next to their name. The roles will be updated instantly. The list of roles and permissions can be viewed at User roles and permissions in the Cloud Manager UI

Results

The member will be assigned the permissions for the role(s).

What to do next

The new member can work in Cloud Manager. The member's authorization is defined by the roles assigned to them.

Deleting a member

As the Cloud Manager administrator, you can delete members of the API Connect cloud administration organization. Once deleted, the user and associated roles are removed, however the user's account still remains in API Connect.

About this task

One of the following roles is required to delete a member:

- Administrator
- Owner

Note: The user account of the deleted user remains in the associated API Connect user registry. The user can still log in to the Cloud Manager user interface but only information links are available; there is no access to view or manage any resources.
The user can be added again as a member at a later time; see Adding members to the admin organization.

Procedure

To delete a member of the cloud administration organization, complete the following steps:

1. In the Cloud Manager, click  Members.
2. Choose Delete from the overflow menu that is adjacent to the member you want to delete.
3. Confirm the deletion.

Results

The member is deleted and removed from the Members list in Cloud Manager.

Role Defaults overview

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Role Defaults concepts

Role Defaults determine the base roles applied to either Provider or Consumer Organizations. The Role Defaults for the Admin organization are not configurable. Role Defaults help to standardize base roles for all organizations. Roles and permissions may be added or modified in the Role Defaults to customize the base roles as needed.

Role Defaults are a "point-in-time" configuration, which effects only new organizations. You can add, delete, or modify roles (except for the Owner, Member, and Viewer roles) in the organization to customize the permissions for each organization.

Rules for editing Role Defaults:

- Edits to Role Defaults are not applied retroactively to existing organizations. Edits apply only to new organizations created after the changes are made.
- Role Defaults apply to all new organizations; roles can then be edited at the organization, catalog, and space level.
- Edits made to roles in an organization do not affect the Role Defaults. Role Defaults are the "parent" and organization roles are the "child". The child inherits from the parent, but changes do not filter up from the organization to the Role Default.

- **Managing role defaults for provider organizations**
  Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

Managing role defaults for provider organizations

Role Defaults are role templates that determine the default roles created in new Provider and Consumer organizations. Cloud Manager ships with a set of pre-configured Role Defaults. As the Cloud Manager administrator, you can edit the pre-configured Role Defaults.

About this task

If you are assigned a role that has permissions to manage Cloud Settings, you can create manage the Role Defaults for the provider organizations.
One of the following roles is required to add roles to the role defaults:

- Administrator
- Topology Administrator
- Owner

Perform the following steps to add or edit roles to the Roles Defaults for provider organizations:

Procedure

1. In the Cloud Manager, click Settings.
2. Select Role Defaults.
3. Click Add to add a new role.
   a. To edit a role, select Edit from the overflow menu for the role.
   b. To delete a role from the Role Default, select Delete from overflow menu and confirm the deletion. Owner, Member, and Viewer roles cannot be deleted.
   Note: Role deletions apply to new members added after the deletion. If a current member is assigned the role, they will continue to have the permissions connected with the role. You need to manage the deletions for each member in the Members screen.
4. Enter the Title for the role. The Name will be auto-generated.
5. Use the check boxes to select the permissions for the role. For a description of the permissions and the actions they enable, see User roles and permissions in the Cloud Manager UI.
6. Save the role.

Results

The role appears in the list of roles for the provider organization Role Defaults. It will be included in the roles that can be assigned to members for all new provider organizations. The roles can be edited for individual organizations.

Monitoring the cloud

API Connect generates events to monitor the status of your cloud.

About this task

You can monitor your API Connect cloud and configure destination targets for your analytics data by using the following tasks:

- **Accessing and configuring analytics**
  Monitor the usage and performance of API calls by using the analytics feature to view, filter, sort, and aggregate your API event data.
- **Configuring audit logging to monitor user operations**
  Configure auditing in IBM API Connect to monitor user operations such as who published which product and when.
- **Reviewing processing status and downloading gateway logs**
  View and download the processing status information for the Gateway services that are enabled in your API Connect.

Accessing and configuring analytics

Monitor the usage and performance of API calls by using the analytics feature to view, filter, sort, and aggregate your API event data.

From the analytics view of the Cloud Manager UI, you can monitor the usage of your published APIs. API events from all catalogs, spaces, and organizations are captured and displayed together in the Cloud Manager analytics view. For more information about the features of the analytics view, see Viewing analytics data in Cloud Manager.

API event records

An API event is logged each time an API operation is invoked on the gateway. The API event record contains information about the API call. When an analytics service is associated with a gateway, all API invocations on that gateway are captured as API event records and sent to the analytics service. The content of the record depends on the logging policy that is set for the operation. For more information about the fields that are displayed in an API event record, see API event record fields.

Analytics configuration options

API Connect offers many configuration options to customize data collection, storage, and retention. For example, you can define filters that refine data to add or remove fields before they are stored. You can choose to offload some, or all, of the data to a third-party storage system. For more information about the analytics configuration options, see Advanced configuration options

Configuring audit logging to monitor user operations

Configure auditing in IBM® API Connect to monitor user operations such as who published which product and when.

Audit logging is useful when you want to monitor the create, read, update, delete, log-in, and log-out activity in your deployment; for example, who made changes, when, and what they changed.

Note: Actions performed by Portal administrators are not captured by the audit feature.

What events are audited?

All create, update, delete, log-in, and log-out operations that are performed by users in the Admin UI, Manager UI, Toolkit, and REST API are captured by this feature. For Portal users, all create, update, and delete operations involving applications are captured.

Beginning in API Connect 10.0.5.3, read operations can also be audited when the **`audit_reads`** setting is additionally enabled (using the toolkit CLI).

Attention: If you choose to enable auditing of read operations for an HTTP endpoint, be aware of that the response might return large payloads, and might contain sensitive information.
Internal calls and calls between system components are not audited because they are part of the product functionality and are not executed by users.

How are audit events logged?

Audit events are logged by sending the information about operations to one or more endpoints of the following types: HTTP, Syslog UDP, Syslog TCP, or Syslog TLS.

- HTTP endpoints:
  Audit logging messages are sent as HTTP/HTTPS requests and use the payload format defined by the Cloud Auditing Data Federation (CADF). If the endpoint requires authentication, you can configure a header that will be included in the audit logging request. Audit logging requests are issued once only, on the assumption that every endpoint is available to receive the requests. There is no error checking to ensure that requests are received and stored by the endpoints, and failed requests are not re-sent. If you suspect that audit logging requests are not successfully reaching an endpoint, you can check the server logs on the console, where any error messages are recorded.

  There are two modes that control how the auditing is sent to an endpoint: blocking and non-blocking. In non-blocking mode (the default), an audit event is sent to the endpoint and the system does not wait for a response from the endpoint. Non-blocking mode provides the best performance. Blocking mode should be used with caution: when an audit event is sent, the system pauses and waits for a response from the endpoint. Blocking mode has a negative impact on performance.

- Syslog endpoints:
  Audit logging messages are sent as syslog messages. If the endpoint requires mutual TLS, you can configure a TLS profile to send the required client certificates. Audit logging requests are issued once only, on the assumption that every endpoint is available to receive the requests. There is no error checking to ensure that requests are received and stored by the endpoints, and failed requests are not re-sent. If you suspect that audit logging requests are not successfully reaching an endpoint, you can check the server logs on the console, where any error messages are recorded.

  All syslog messages are sent as non-blocking regardless of the auditing mode, since syslog messages are designed to be fire and forget (syslog was originally a UDP protocol, which by its nature does not have any acknowledgment). Blocking is only used for HTTP endpoints.

Note: With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What's included in the audit logging request?

- HTTP endpoints:
  The payload containing the audit logging record includes information about the user who executed the operation, the date and time of the call, the resource affected by the call, the operation performed, and the payload. If you enabled audit logging for read operations, the payload might also contain the properties from the response (based on your configuration settings).

  To see the most recent set of fields that are included in the payload, refer to the OpenAPI schema for the audit logging request in the Provider API, which you can download at https://apic-api.apiconnect.ibmcloud.com/v10/10.0.5.LATEST.html#/IBMAPIConnectPlatformProviderAPI_200/overview.

```

- Syslog endpoints:
  The nature of syslog messaging means that the information logged is less structured and shorter than information logged using structured HTTP endpoints. With Syslog, the information is more of a summary.

  The following sample response shows payloads for an audit logging message directed to a syslog endpoint (IDs and users are not real):

```
The user admin:default-idp-1/admin has deleted the resource Org 'alpha (Alpha title)', id 19cf81c7-7cb3-43de-b5e5-
d92cdfb26214 and url https://localhost:3003/api/orgs/19cf81c7-7cb3-43de-b5e5-d92cdfb26214
The user admin:default-idp-1/admin has deleted the resource Gateway Service 'webhook-gw-v5 (Webhook Gateway Service (v5)
title)', id 08b87e25-616d-451e-8766-bad1c7b82a42 and url https://localhost:3003/api/orgs/69c878db-4f11-4c3e-9499-
10daa25f04de/availability-zones/cb2caa3d-d619-4c2e-85f8-709956495a7b/gateway-services/08b87e25-616d-451e-8766-bad1c7b82a42
The user provider:default-idp-2/steve@example.com has created the resource Catalog 'climbon:1.0.1 (The climbon product
description)', id 665036df-28ad-447e-b8de-fe9d6967b66d and url https://localhost:3003/api/catalogs/19cf81c7-7cb3-43de-
b5e5-d92cdfb26214/8641fda7-43f8-4e59-b405-58a4844016c9/products/665036df-28ad-447e-b8de-fe9d6967b66d
The user admin:default-idp-1/admin has read the resource Cloud Setting 'cloud-setting', id settings and url
https://localhost:3003/api/cloud/settings
```

Verifying that the endpoint is receiving audit logging messages

By default, auditing operates in **non_block** mode to ensure best performance. In **non_block** mode, each audit logging message is sent immediately without waiting to ensure that the previous message was received. If you suspect that audit logging messages are not being received by the endpoint, download the server logs from the Kubernetes console and examine the apim microservices file for messages related to the connection state. Review the messages to validate that the connection was successful or to further diagnose issues.

For HTTP endpoints (not available for Syslog endpoints), you can test the connection by issuing a "test-connection" call using either the toolkit or a REST API. A response status of **204** indicates that the call was successful and the endpoint is available. The following example contains the payload from a connection test (IDs and users are not real):

```
{
  "id": "8d8eaaa2-1b46-4dcb-cadf-639d7d1f7f20",
  "typeURI": "http://schemas.dmtf.org/cloud/audit/1.0/event",
  "action": "create",

```

Tip: To ensure that audit logging messages are not lost due to an unavailable endpoint, verify each endpoint periodically.

- **Configuring the audit settings**
  Use the Cloud Manager UI or the toolkit CLI to enable auditing and configure settings.

Configuring the audit settings

Use the Cloud Manager UI or the toolkit CLI to enable auditing and configure settings.

About this task

The audit feature tracks platform-level changes in API Connect through the use of platform APIs, CLI, and Web UI. For information on tracking run-time API execution, see API Analytics.

You can configure audit settings using either the Cloud Manager UI, or the Toolkit CLI.

Using the Cloud Manager UI to configure audit settings

Use the Cloud Manager user interface to enable auditing of customer API calls.

Before you begin

Configure one or more audit endpoints where logging data can be directed, and validate that every endpoint is available by testing the connection as explained in Configuring audit logging to monitor user operations.

About this task

By default, auditing is disabled. If you enable auditing, the API Connect management node emits audit events as messages and sends them to the endpoint for storage.

Note: Auditing for read operations can only be enabled and configured using the CLI.

Procedure

1. In the Cloud Manager, click Settings > Audit Setting > Edit.
2. Click Enable to enable the audit feature, or Disable to disable it.
3. Select an audit mode:
   - Non-blocking - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
   - Blocking - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.
     Note: Blocking mode is only applied to HTTP endpoints and is ignored for Syslog endpoints.
4. Click Add and select the type of endpoint that you want to add (you must add at least one endpoint).
   Endpoints can be of the following types: HTTP, Syslog UDP, Syslog TCP, or Syslog TLS.
5. In the Endpoints section, fill in the fields to describe the new endpoint:

   HTTP
   - URL - Required, must not be empty. The URL of the server where audit logging messages will be sent.
     If you previously saved the audit settings with an empty URL and experienced problems, you can edit the URL to correct it.
   - TLS client profile - Optional. The URL of the server where the endpoint's TLS client profile is stored.
   - Header name and Header value - Optional. Multiple headers are allowed (click Add to add another header). For each header, specify the header name and the header value.

   Syslog UDP
   - Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com.
     Do not include the **`syslog://`** protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.
   - Port - Optional. The port number where audit logging messages should be directed.

   Syslog TCP
   - Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com.
     Do not include the **`syslog://`** protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.
   - Port - Optional. The port number where audit logging messages should be directed.

   Syslog TLS
   - Host name - Required, must not be empty. The host name of the server where audit logging messages will be sent; for example: www.example.com.
     Do not include the **`syslog://`** protocol with the host name. When audit logging messages are directed to the host server, the protocol is added to the host name programmatically.
   - Port - Optional. The port number where audit logging messages should be directed.
   - TLS client profile - Optional. The URL of the server where the endpoint's TLS client profile is stored.
6. Verify that you can reach the endpoint by clicking Test.
7. To specify another endpoint, click Add at the beginning of the "Endpoints" section.

8. When you finish adding endpoints, click Save to save your settings.

Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What to do next

If you suspect that audit logging messages are not being received by the endpoint, see Verifying that the endpoint is receiving audit logging messages for information on validating the connection.

Using the CLI to configure audit settings

Use the IBM API Connect toolkit CLI to enable auditing of API calls.

Before you begin

Configure one or more audit endpoints where logging data can be directed, and validate that every endpoint is available by testing the connection as explained in Configuring audit logging to monitor user operations.

About this task

By default, auditing is disabled. If you enable auditing, the API Connect management node emits audit events as messages and sends them to the endpoint for storage.

Use the following `audit_setting` options to enable auditing with the CLI toolkit:

- `enable` - Boolean, defaults to `false` (no audit). Set to `true` if you want to enable auditing.
- `mode` - Enumerated, defaults to `non_block`. The audit mode determines how audit requests are timed when they are sent to the endpoint:
  - `non_block` - Default value, offers the best performance. Each request is passed immediately without waiting for a response to the previous request. This is susceptible to errors if a request is dependent on the results of an earlier request whose response is not received before the new request is sent.
  - `block` - If you select this mode, expect a degradation in performance. Each request is allowed to finish execution before the next request is sent. This mode results in fewer errors when requests are dependent on the responses of earlier operations, but the delayed requests slow the network.
    Note: Block mode is only applied to HTTP endpoints and is ignored for Syslog endpoints.
- `audit_reads` - Use this setting to enable auditing of read operations:
  - `enable` - Boolean, defaults to `false` and no audit events are sent to the endpoint for read operations. Set to `true` if you want to enable audit logging for read operations.
  - `response_data_to_http_endpoints` - Configure additional settings for HTTP endpoints only (the settings do not apply to Syslog endpoints).
    - `enable` - Boolean, defaults to `false` and audit events for GET operations are sent to the HTTP endpoint with no response data in the event. Set to `true` if you want to include the response data.
      Attention: If you choose to include the response data, be aware that the response might return large payloads, and might contain sensitive information.
    - `list_results_limit` - Integer, must be 0 or larger. Use this setting to specify the maximum number of results of `GET list` operations to include in the audit message (default is 0 results).

      If `audit_reads` is enabled, then the audit message for a `GET` of *a single object* (for example, `GET /orgs/admin`) always includes all of the properties of the response object.

      If the `list_results_limit` is set to 0, then the audit message for a `GET` to *list objects* (for example, `GET /orgs`) does not include any objects from the GET response. If you set the `list_results_limit` to a value greater than 0, then the audit message includes all properties from the first `list_results_limit` number of objects from the `GET /orgs` response.
- `endpoints` - Array of strings. You must specify at least one endpoint where the audit logging messages are sent. Endpoints can be of the following types: HTTP, Syslog UDP, Syslog TCP, or Syslog TLS.
  For HTTP and Syslog TLS endpoints, you can optionally include a TLS client profile URL. For HTTP endpoints, you can additionally include one or more optional headers. For example, if the endpoint requires an authorization header, you can include it in the endpoint setting.
  - `endpoint_type` - String. Required. Allowed values are: `http`, `syslog_udp`, `syslog_tcp` or `syslog_tls`.
  - `endpoint` - String. Required, must not be empty or blank. The URL of the server where audit logging messages will be sent. Include the protocol (`http://` or `syslog://`) and the port, if applicable. For example, `syslog://<hostname>:<port>`.
  - `tls_client_profile_url` - String. Optional; supported only for HTTP and Syslog TLS endpoints. The URL of the server where the endpoint's TLS client profile is stored.
  - `headers` - String. Optional; supported only for HTTP endpoints. Multiple headers are allowed. For each header, specify the header name and the header value using the format shown in the example.

The endpoint setting can be lengthy, so uploading the settings in a file helps to avoid errors. Format the settings as a .yaml file (you can choose the file name) and upload the file using the toolkit CLI. The following example enables auditing in non-blocking mode with multiple endpoints to demonstrate how the settings should be formatted.

```
audit_setting:
  enabled: true
  mode: non_block
  audit_reads:
    enabled: true
    response_data_to_http_endpoints:
      enabled: true
      list_results_limit: 0
  endpoints:
    - endpoint_type: syslog_udp
      endpoint:
        endpoint: syslog://syslog-audit-endpoint.example_1.com:514
    - endpoint_type: syslog_tls
      endpoint:
```

```
        endpoint: syslog://syslog-tls-audit-endpoint.example_1.com:1601
        tls_client_profile_url: https://security.tls_example.com/api/orgs/d8eac736-b4e2-3aa6-c7ff-978a4cd19d0b/tls-client-
profiles/19d0f087-b4e2-3aa6-926b-9f6d51d028c3
    - endpoint_type: http
      endpoint:
        endpoint: https://mutt-audit-endpoint.example_1.com/auditing
    - endpoint_type: http
      endpoint:
        endpoint: https://auditing-endpoint.example_1.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
        tls_client_profile_url: https://security.tls_example.com/api/orgs/d8eac736-b4e2-3aa6-c7ff-978a4cd19d0b/tls-client-
profiles/19d0f087-b4e2-3aa6-926b-9f6d51d028c3
      headers:
        authorization: Basic c3Bvb246c2ltb25rYXRpZXVtYQ==
    - endpoint_type: http
      endpoint:
        endpoint: https://auditing-endpoint.example_2.com/inputs/64e38c02-acd9-6530-76f8-dd0f336d7b11
      headers:
        authorization: Basic c3Bvb246c2ltb24=
        x-header: ForYourEyeOnly
```

Procedure

1. Create a YAML file with the audit settings as shown in the example.
   For information on using input files with the toolkit CLI, see Reading input from the command line.

2. Run the following command to log in to a management server as a member of the cloud administration organization:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   Cloud settings are stored on a management server and you must log in to the server before you can access the settings with the CLI.

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope admin --server mgmt_endpoint_url --fields title,realm
   ```

   For example:

   ```
   apic identity-providers:list --scope admin --server myserver.com --fields title,realm
   total_results: 2
   results:
     - title: Cloud Manager User Registry
       realm: admin/default-idp-1
     - title: Corporate LDAP user registry
       realm: admin/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`.
   For more information on logging in, see Logging in to a management server.

3. Upload the YAML file with the auditing settings by running the following command:

   ```
   apic cloud-settings:update --server mgmt_endpoint_url my_audit_settings.yaml
   ```

4. Run the following command to log out of the management server:

   ```
   apic logout --server mgmt_endpoint_url
   ```

Results

With the microservices nature of API Connect, any changes to the audit settings can take up to five minutes to be fully honored by all of the microservices supporting it.

What to do next

If you suspect that audit logging messages are not being received by the endpoint, see Verifying that the endpoint is receiving audit logging messages for information on validating the connection.

API Gateway only

Reviewing processing status and downloading gateway logs

View and download the processing status information for the Gateway services that are enabled in your API Connect.

About this task

Check the status of API events processed by the gateway, and download gateway logs as needed. For example, you might want to check whether a Product was published and is available on the gateway before using one of its APIs. Or you might notice that API events are processing slowly and want to see if all events for a specific gateway service are affected.

You can review or download a gateway's processing status in the Cloud Manager user interface, or by using the toolkit CLI to retrieve the information.

Notes: You can only obtain processing status information for the DataPower® API Gateway. This feature is not supported for the DataPower Gateway (v5 compatible) service or the Event Gateway service.

Using the UI to view the gateway processing status

About this task

Use the Cloud Manager user interface to view or download the processing status information for all the DataPower API Gateway.

Procedure

To check the status of API events processed by the gateway and download gateway logs, complete the following steps:

a. Log in to Cloud Manager.

b. In the navigation pane, click Configure topology.

c. On the topology page, you can view the processing status and download the gateway logs.

- To view the processing status, complete the following steps:
  - Click ⋮ next to the gateway service and select View status.
    The View status page displays a list of the events that were sent to the gateway.

    A status icon displays for each service name to provide a quick indication of that service's status:

    - Normal: Between 0 and 10 events are waiting to be processed
    - Increased: Between 10 and 20 events are waiting to be processed
    - High: More than 20 events are waiting to be processed

    In addition, for each event, you can see the following information:

    - Event type: The action performed by the event; for example, subscribing to a product, deleting an application, or creating a new consumer organization.
    - Category: The feature area affected by the event; for example, subscriptions, applications, or consumer organizations.
    - Time: The time when the event was processed by the gateway service.
    - Status: The current event's processing status; for example, Queued (not yet sent for processing), Sent (but not processed yet), or Processed (complete).
      The number of events in the Queued and Sent states determine the status level for the service.

    The display includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

- To download gateway logs, complete the following steps:
  - Click ⋮ next to the gateway service and select Download logs.
  - Downloads a compressed file to your computer with a name that uses the format *<gateway-name>*.zip for example v6gw.zip.

Using the CLI to obtain a gateway's processing status

About this task

You can use the developer toolkit CLI to obtain information about the processing status for the Gateway services that are enabled in your Catalogs and Spaces.

The processing status information is returned in the following fields:

Field	Description
`service_up_to_date`	If `true` then all outstanding events have been processed by the Gateway service.
`service_state`	An overall status summary of the various states of events and processing by the Gateway service: • `green` indicates normal status with between 0 and 10 events waiting to be processed • `orange` indicates that between 10 and 20 events are waiting to be processed • `red` indicates that more than 20 events are waiting to be processed
`last_processed_event`	Details of the last event that was processed by the Gateway service, helping to provide a timeline of when the last event was processed, and some statistics about how long ago it was and how long the processing took.
`last_sent_event`	Details of the last event that was sent to the gateway service
`number_of_outstanding_sent_events`	The number of events that have been sent but not yet processed by the Gateway service.
`number_of_outstanding_queued_events`	The number of events that have been queued but not yet sent to the Gateway service.
`first_failed_event`	This is the first event for which the gateway sent a failed status.

The following example shows a "green" response that includes the status information and the list of sent events:

```
gateway_processing_status:
  service_up_to_date: false
  service_state: green
  last_processed_event:
    event_id: 40e1a564-2aea-429b-9d35-f588218688a1

    processed_at: '2020-06-02 22:32:10.838+00'
    generated_at: '2020-06-02 22:31:43.38615+00'
    filter: product_del
    event_processing_time: 22597
    elapsed_time_since_last_processed_event: 18427
  last_sent_event:
    event_id: 93d0bf8f-ebfb-4a8b-aa22-7f805719d5c8
    title: >-
      Update Product (name-version:lts-cat0-product-11:1.0.0, id:
      d0bf799f-7f3a-4546-b267-a85c6a7f4b10) by user shavon0
    sent_at: '2020-06-02 22:32:28.426+00'
    generated_at: '2020-06-02 22:32:25.505109+00'
  number_of_outstanding_sent_events: 37
  number_of_outstanding_queued_events: 1
```

The result includes events that were not processed yet, as well as the last event processed. If a particular event is not listed as Sent or Queued, then that event was already processed.

Procedure

To obtain processing status information for a Gateway service, complete the following steps:

1. Log in to your API Connect Management server as a provider organization member, by using the following command:

   ```
   apic login --server api_platform_endpoint_url --username user_id --password password --realm admin/identity_provider
   ```

   where:
   - *api_platform_endpoint_url* is the platform API endpoint URL.
   - *user_ID* is the user ID of your provider organization account, and is the same as the user ID that you use to log in to the API Manager user interface.
   - *password* is the password for your administrator account.
   - *identity_provider* is the identity provider that is used to authenticate API Manager users.

   For example:

   ```
   apic login --server platform-api.myserver.com --username myuser --password password --realm provider/myldap
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you need to be logged in to an admin real to use this command):

   ```
   apic identity-providers:list --scope provider --server api_platform_endpoint_url --fields title,realm
   ```

For example,

```
apic identity-providers:list --scope admin --server api_platform_endpoint_url  --fields title,realm
total_results: 1
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
For full details on how to log in to your management server from the CLI, see Logging in to the management server.

2. Obtain the Gateway processing status for a Gateway service that is enabled in a catalog by running the following command:

```
apic gateway-services:get --server mgmt_endpoint_url --org organization_name  gateway_service_name --fields
"add(gateway_processing_status,events,webhook_state)" --output -
```

where:

- *mgmt_endpoint_url* is the platform API endpoint URL.
- *organization_name* is the name of the provider organization that contains the catalog.
- *gateway_service_name* is the name of the Gateway service whose processing status you want to obtain.
- The `--fields "add(arguments)"` parameter can include either, or both, of the following arguments (separated with a comma):
  - `gateway_processing_status`: returns the total number of sent events, queued events, and processed events
  - `events`: returns lists of sent events with details about each event
  - `webhook_state`: this is the current state of the webhook subscription between API Manager and the gateway

For example:

```
apic gateway-services:get --server platform-api.myserver.com --org myorg my-gateway-service --fields
"add(gateway_processing_status,events,webhook_state)" --output -
```

Changing your Cloud Manager password and profile information

You can change your Cloud Manager password and update your profile information.

Procedure

To change your password or profile information, follow these steps:

1. Log in to the Cloud Manager user interface.
2. Click the User icon  , and then select My Account.
3. In the Profile section, enter a new email address and First Name and Last Name for the account owner.
4. Click Save.
5. In the Change password section, enter your current password and your new password, and confirm the new password.
   The password must contain six characters at a minimum. It must contain at least three of the following types of characters:
   - Lowercase letters
   - Uppercase letters
   - Numbers
   - Characters from the following list of allowed punctuation and special characters:

```
!
\"
#
$
%
&
\
(
)
*
+
,(comma)
- (dash/hyphen)
.(period)
/
:(colon)
;(semi-colon)
<
=
>
?
@
[
\\
]
^
_ (underscore)
` (back quote/grave accent)
{
| (pipe)
}
~ (tilde)
```

   The password cannot contain more than two consecutive repeating characters.

6. Click Save.

Results

Your profile information and password are changed.

- Configuring and managing your server environment

Resolving login problems by increasing HTTP header size

You can resolve login problems for the Cloud Manager UI by increasing the maximum HTTP client header size.

About this task

Login attempts to the user interface might fail with error **502 (Bad Gateway)**. This error can occur when logging in from a browser that has a large number of cookies. The error occurs because size of the login request exceeds the maximum HTTP client header size.

The maximum HTTP client header size is limited for security reasons. To workaround this issue, you can clear the browser cache and cookies, or open an incognito window from the browser, and then retry the login.

Alternatively, you can increase the maximum HTTP client header size. Use caution when increasing the maximum size because larger headers can raise a security risk to your system.

Procedure

1. **SSH** to your management system or appliance.
2. Enter the following commands:

```
kubectl get deployment -n namespace  | grep apim
kubectl edit deployment -n namespace management-apim
```

3. In the **env** section of the deployment configuration, change `--max-http-header-size=12000` to a larger value that works for your environment. For example:

```
 - name: NODE_OPTIONS
          value: --max-old-space-size=8094 --max-http-header-size=16000
```

4. Save the updated configuration.
5. Run `kubectl get pod -n namespace` a few times until the new `management-apim` pods are up and running.

Onboarding a new admin for Cloud Pak for Integration

Use the API Connect toolkit CLI to create a new admin account for use with Cloud Pak for Integration.

About this task

If you changed the local admin account for Cloud Pak for Integration, you must create a new admin user in API Connect to ensure that the new Cloud Pak for Integration admin can log in to API Connect with the Common Services User Registry.

Procedure

1. Download and install the API Connect toolkit CLI and credentials file as explained in Installing the toolkit.
2. Log in to the toolkit CLI.
   Logging in to the toolkit CLI requires the endpoint URL for your API Connect management server. In Cloud Pak for Integration, the URL indicates the location of the management server within the Cloud Pak for Integration deployment.

   a. Determine the URL to the API Connect management server by running the following command:

   ```
   oc -n APIC_namespace get mgmt APIC_instance -o jsonpath="{.status.zenRoute}" && echo ""
   ```

   The response looks like the following example URL:

   ```
   apic-mgmt-admin-apic.deve-cip-hlag-8e86d3798137c73f524cf9-0000.eu-de.containers.appdomain.cloud
   ```

   b. Log in to the API Connect toolkit CLI by running the following command:

   ```
   apic -s API_Connect_URL login -u admin -p <password> -r admin/default-idp-1
   ```

   where ***API_Connect_URL*** is the URL of the management server in your API Connect instance.

3. Create a new admin account by completing the following steps.
   Use the toolkit CLI to create an admin account in the Common Services User Registry and then add the new admin to the API Connect **administrator** role.

   a. Create a YAML file called newCp4iAdmin.yaml with the following information for the new admin account.

```
username: <new_cp4i_admin_username>
first_name: CP4I
last_name: Administrator
```

b. Create the CP4i admin account by running the following command:

```
apic -s API_Connect_URL users:create -o admin --user-registry common-services newCp4iAdmin.yaml
```

c. Verify that the account was created by running the following command:

```
apic -s API_Connect_URL users:get -o admin --user-registry common-services <new_cp4i_admin_username> --output -
```

d. Get the new admin account's URL by running the following command:

```
apic -s API_Connect_URL users:list -o admin --user-registry common-services | grep <new_cp4i_admin_username> | awk
'{print $4}'
```

e. Get the URL of the API Connect **administrator** role by running the following command:

```
apic -s API_Connect_URL roles:list --scope org -o admin | grep -w administrator | grep -v topology | awk '{print $2}'
```

f. Create a YAML file called newcp4iadminmember.yaml with the following content:

```
name: <new_cp4i_admin_username>
user:
  url: <user_URL>
role_urls:
  - <role_URL>
```

g. Use the newcp4iadminmember.yaml file to add the new admin as a member of the API Connect instance's admin organization.
Create the new member by running the following command:

```
apic -s API_Connect_URL members:create --scope org -o admin newcp4iadminmember.yaml
```

h. Verify that the new admin account works by using it to log in to the Cloud Manager interface in your API Connect instance.

4. Remove the old Cloud Pak for Integration admin user from API Connect.
After you verify that the new Cloud Pak for Integration admin can log into the API Connect Cloud Manager interface, delete the previous Cloud Pak for Integration admin account.

a. Remove the previous admin from the membership of the API Connect admin organization by running the following command:

```
apic -s API_Connect_URL members:delete --scope org -o admin cs-admin
```

When you initially deployed API Connect as a component of Cloud Pak for Integration, the admin username was **admin** and the member in the API Connect admin organization was **cs-admin**. If the **cs-admin** member does not exist in the admin organization, then the Cloud Pak for Integration admin user was changed after deployment. In this case, the member uses the same name as admin account's user name. Delete the member with that name:

```
apic -s API_Connect_URL members:delete --scope org -o admin <old_cp4i_admin_username>
```

b. Delete the previous Cloud Pack for Integration admin user account from the Common Services User Registry by running the following command:

```
apic -s API_Connect_URL users:delete -o admin --user-registry common-services <old_cp4i_admin_username>
```

Extending the Gateway server behavior

To support your enterprise requirements, you can extend the Gateway servers within IBM® API Connect to provide extra enforcement behavior.

API Connect Gateway servers uses a subset of DataPower® enforcement capabilities. You can supply DataPower® Extensions to customize these enforcement capabilities further.

The DataPower extensibility function can be used to perform actions that include schema validation, antivirus scanning, message filtering, authentication, and authorization, token translation, message enrichment, encryption & decryption, digital signing, and validation and message transformation. For more information, see IBM DataPower documentation.

For information on the different types of gateway, see API Connect gateway types.

Important: Gateway server extensions must not be used to modify objects that cause the **apic-gw-service** object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the **apic-gw-service** object to restart, lead to unpredictable behavior in the Gateway service.

- **Gateway extension guidelines - DataPower Gateway (v5 compatible)**
  Before you develop your extensions to the DataPower Gateway (v5 compatible), consider these guidelines.
- **Gateway extension guidelines - DataPower API Gateway**
  Use API Gateway extensions to customize and configure the DataPower application domain in ways that are not possible from the API Manager UI.
- **Configuring your Gateway server extensions**
  You can add extra DataPower enforcement capabilities to a gateway service by uploading a .zip file that defines the required extension behavior, and then enabling the extension in DataPower.

DataPower Gateway (v5 compatible)

Gateway extension guidelines - DataPower Gateway (v5 compatible)

Before you develop your extensions to the DataPower Gateway (v5 compatible), consider these guidelines.

Note: These guidelines apply to the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway, see Gateway extension guidelines - DataPower API Gateway.
For information on the different types of gateway, see API Connect gateway types.

You can download sample gateway extensions from https://github.com/ibm-apiconnect/dp-extensions.

You can create DataPower Processing Rules that can extend the enforcement behavior of the IBM® API Connect Gateway server at the following locations:

- `pre-request` extension:
  - Before the Gateway server begins to use the policies in the assembly to process the request.
- `post-request` extension:
  - After the Gateway server processes all of the policies in the assembly up to the proxy policy, if a proxy policy is used.
  - After the Gateway server processes all policies in the assembly, but before any catch logic is processed, if a proxy policy is not used.
- `post-response` extension:
  - After the Gateway server processes all of the remaining policies in the assembly after the proxy policy (including catch logic), but before the response is returned to the client application, if a proxy policy is used.
  - After the Gateway server processes the catch logic, but before the response is returned to the client application, if a proxy policy is not used.
- `post-error` extension:
  - If an error occurs, then before the Gateway server returns the error response to the client application.

To configure the Gateway server to call your extension Processing Rule, you must create an XML file that indicates the extension location and Processing Rule name. For example,

```
<extensions>
<extension location="pre-request">CustomRule1</extension>
<extension location="post-request">CustomRule2</extension>
<extension location="post-response">CustomRule3</extension>
<extension location="post-error">CustomRule4</extension>
</extensions>
```

The `<extension>` element entries are optional for any of the locations. Refer to the Gateway server Extension schema for the XML file syntax.

An extension Processing Rule can be applied to a specific organization or to all of the organizations and Catalogs. If the `<extension>` element does not have a tenant attribute, then the `<extension>` element is applied to all of the organizations. The following example shows an `<extension>` element without a tenant attribute.

```
<extension location="post-error">gen_error_handling</extension>
```

To apply an extension Processing Rule to a specific organization, enter the organization name as the value for the tenant attribute in the `<extension>` element. The following example shows an <extension> element with a tenant attribute value of *organization1*.

```
<extension location="post-error" tenant="organization1">organization1_error_handling</extension>
```

If you want to exclude a specific organization in an extension Processing Rule, enter the organization name as the value for the tenant attribute in an empty `<extension>` element. Add the empty `<extension>` element immediately after the custom rule `<extension>` element that you want to exclude the organization from. The following example shows an empty <extension> element with a tenant attribute value of *organization1*.

```
<extension location="pre-request">a_specified_CustomRule</extension>
<extension location="pre-request" tenant="organization1"></extension>
```

Important: An extension Processing Rule with a specified tenant attribute takes precedence over an `<extension>` element that applies to all of the organizations. Also, only one extension Processing Rule is applied to each extension location.
This XML file must be saved to the following location and included in your DataPower exported configuration .zip file:

```
local:///ext/extensions.xml
```

There can be only one DataPower exported configuration .zip file added to a Gateway server in API Connect.

CAUTION:

- Do not modify these files directly in the DataPower API Gateway file system, use the gateway extension mechanism described on this page.
- Do not apply gateway extension modifications to configuration in the local:/config-sequence.cfg file.
- Do not use Gateway server extensions to modify objects that cause the `apic-gw-service` object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the `apic-gw-service` object to restart, lead to unpredictable behavior in the Gateway service.

DataPower configuration restrictions

All Processing Rules have read access to the INPUT context.

Processing Rules must not rely on context variables that are created by the IBM Gateway server enforcement configuration, because those configuration variables might change in the future.

All Processing Rules except Before Request can transform or alter the message flowing through the Gateway server. Ensure that the Processing Rule returns the desired message output context back to the Gateway server at the end of processing.

To avoid name conflicts, all DataPower configuration object names prefixed with `webapi` are reserved for IBM use.

The following folders cannot be modified:

- `local:///isp/*`
- `local:///gwapi/*`

As a best practice, avoid adding asynchronous actions in your custom Processing Rules because they increase the use of memory per transaction.

Gateway extension guidelines - DataPower API Gateway

Use API Gateway extensions to customize and configure the DataPower application domain in ways that are not possible from the API Manager UI.

Note: These guidelines apply to the DataPower® API Gateway. If you are using the DataPower Gateway (v5 compatible), see Gateway extension guidelines - DataPower Gateway (v5 compatible).
For information on the different types of gateway, see API Connect gateway types.

Some common uses of API Gateway extensions are:

- Adding other DataPower services to the application domain.
- Deploying user defined policies.
- Deploying v5 emulation policies.

The extension structure is a zip file that contains a manifest file and one or more extension implementation files that the manifest file references. See Gateway extensions manifest for details on the manifest file JSON structure as well as the supported implementation types.

- gateway_extension.zip
  - manifest.json
  - extension_implementation_1.zip
  - extension_implementation_2.zip

You upload the extension .zip file to an API Connect Gateway service, and enable the extension, as described in Configuring your Gateway server extensions. Gateway server extensions can be deployed without having to restart the DataPower API Gateway.

Gateway extension limitations

This section details the limitations of the extensions to the DataPower API Gateway.

- If you use an extension to create a user-defined policy and then delete the extension, the extension is removed from the filesystem, but the configuration sequence is not triggered to clean up related files. For the policy to be cleaned up, you must send a modified extension that explicitly removes the user-defined policy from `apic-gw-service`, as in the following example.

  ```
  apic-gw-service
      no user-defined-policies udp-basic_1.0.0
  exit
  ```

  Note: This limitation does not apply only to user-defined policies, but any object customization that adds a reference to another object.
- `user-defined-policy-yaml` policies that use or reference another policy can be deployed only after the referenced policy has been advertised to API Manager. The deploy type must be set to `deferred` and the Gateway Service must be restarted.
- v5 policies that contain files outside of the `/policy` directory are not supported. If multiple v5 policies reference the same file outside the `/policy` directory, the last applied policy will overwrite the file and will be used by all policies that reference it. Removing any policy that contains the file will cause the file to be deleted and may cause errors for the remaining policies that use it.
- If an extension contains or references objects and files that are also referenced by other objects outside of the extension, deleting the extension can cause errors that are difficult to troubleshoot.
- It is possible to delete an extension that is referenced by published APIs. This may cause those API requests to return errors.
- For an extension type of `user-defined-policy`, extra assembly functions may be present in the DataPower import `.zip` file, even if there is no `.yaml` file to indicate their presence. Using these functions without declaring them using a `.yaml` file is not supported. A policy `.yaml` file is required for each policy you want to advertise to API Manager.
- Extension type `user-defined-policy-yaml` may leak generated Gateway script `.js` files in temporary:/js/ or `.xslt` files when deleted.
- Extension types that use SOMA imports must use new objects with no overrides. If you override a singleton or shared object using an extension of this type, then the object will not be restored to its previous state when the extension is deleted, and those objects may be missing after the extension is deleted. You must then restore any needed objects.
- During APIM lifecycle events, customization made to objects created by the DataPower API Gateway connect service using CLI command file extensions may be temporarily lost. For this type of customization, use the GWD extension type.

- **Gateway extensions manifest**
  The gateway extensions manifest controls how gateway extensions are applied to the DataPower API Gateway.
- **v5 policy emulation limitations**
  This page details the limitations of v5 policy emulation for the current release.

API Gateway

Gateway extensions manifest

The gateway extensions manifest controls how gateway extensions are applied to the DataPower® API Gateway.

The gateway extensions manifest enables you to deploy multiple extension implementations in a single package. The manifest is a JSON file that lists the extensions `.zip` files to be applied and when they are to be deployed. You can also use the manifest to enable v5 policy emulation for the API Connect gateway service. V5 policy emulation enables you to deploy supported v5 built-in policies and custom policies, and manage them from API Manager without having to rewrite them for DataPower API Gateway. V5 policy emulation is supported only for policies that are applied to the Gateway service scope.

The `manifest.json` file must be at the root level of the extensions `.zip` file, along with the gateway extension files specified in the manifest. For example:

```
manifest.json
jws-sign-policy.zip
add_udp.zip
```

The `manifest.json` file contains the following sections.

`properties` section

The properties section determines whether to enable the v5 framework to deploy supported v5 built-in policies and custom policies and manage them from API Manager without having to rewrite them for DataPower API Gateway.

Table 1. `properties` section properties

Property	Description
`deploy-policy-emulator`	Determines whether to enable v5 framework emulation. Valid values are `true` and `false`. v5 framework emulation is enabled for the API Connect Gateway service if `deploy-policy-emulator` set to `true`, if a v5 policy is detected in the files list, or if a `deploy-policies` entry is specified.
`deploy-policies`	Contains a list of built-in policies to advertise for v5 emulation. The following policies are supported. • `activity-log_1.5.0` • `gatewayscript_1.0.0` • `if_1.5.0` • `invoke_1.5.0` • `proxy_1.5.0` • `redact_1.5.0` • `switch_1.5.0` • `validate-usernametoken_1.0.0` • `xslt_1.0.0`
`defer-all-override`	An override toggle to force the deployment property of all extension entries (including V5E) to be deferred. When enabled, the user must restart the `apic-gw-service` object to apply any extension events.

`files` section

The `files` section is an array of file entries that reference extension implementations. Each entry must reference a file that is in the `extension.zip` file (or the extension is rejected).

Table 2. `files` section properties

Property	Description
`filename`	The name of the file that contains the extension implementation. This property is required and cannot be changed while the extension is deployed as part of an update.

`type`	The type of extension implementation to be deployed. This property is required.
	
	The following types are supported.
	
	`dp-import`
	A DataPower import used to add additional configuration and/or services to a gateway. Like the extension type, but `dp-import` persists the configuration on physical or virtual DataPowers.
	
	Note: A `dp-import` file cannot be used to change the `apic-gw-service` object. If it is configured for this purpose, the extension is rejected.
	`extension`
	A legacy API Gateway extension that can be used to add additional configuration to a gateway. `Extension` should not be used to modify objects created by the gateway service, see gwd_extension for that use case. For more information, see CLI command file extensions.
	`gwd_extension`
	A JSON file that allows users to customize objects created by the API Connect gateway service. Only one `gwd_extension` is allowed in the manifest. For more information about the `gwd_extension`, see GWD extension type.
	`policy-v5`
	A complete, valid v5 policy implementation. You can apply a fully implemented and valid v5 policy at the gateway service level or restrict it to specific catalogs. By default, the v5 policy is available at the gateway service level, making it available to all catalogs. To limit its availability to one or more catalogs, refer to the `catalog` and `catalog-scope` properties below.
	For more information, see Authoring policies for the DataPower Gateway (v5 compatible).
	`user-defined-policy`
	A native API Gateway policy packaged in a DataPower import zip. Using a DataPower import to apply the policy implementations allows the configuration to persist through restarts and upgrades on virtual and physical forms. The import might contain one or more policy implementations. This policy type is always global scoped. For more information, see Defining, packaging, and publishing a global-scoped policy for the API Gateway.
	`user-defined-policy-yaml`
	A YAML file that includes an assembly. This policy type is always global scope. If the assembly references another user-defined policy, that policy must already be advertised to the API Manager before it can be deployed. For more information, see Working with global policies.
	`v5_extension`
	A migrated v5 extension that the migration utility generates. Only certain parts of v5 extensions are usable in API Gateway. For more information, see Migrating gateway extensions.
	`v5_extension` is reserved for v5 extensions that the migration utility creates. Do not manually create this type of extension.
	Note:
	V5E is intended to allow users to migrate from V5 without editing their APIs. V5E type policies cause known performances degradations in the API gateway. To improve performance of V5E policies, it is recommended to convert them to native policies.

`deploy`	When to process manifest file entry events such as create, update, and delete.
	
	`immediate`
	Process entry event as soon as the extension is received by the API Connect gateway service. All gateway nodes apply the extension in parallel.
	Warning: `immediate` can cause an outage across the cluster, dependent on what the extension does.
	`deferred`
	Process event after the API Connect gateway service is restarted. This value is the default setting and allows users to roll outage causing extensions events to one node at a time. When a DRR occurs this property is ignored, and all entries are deployed immediately.

Property	Description
`catalog`	Indicates that a v5 policy is to be used only by certain catalogs and should not be advertised as a gateway service-level user policy. This property is valid only if the file type is `policy-v5`. The `catalog` value must be in the format ***`orgname_catalogname`***. Note: Use this property while defining a policy with same name and version but with different implementations per catalog.
`catalog-scoped`	Indicates that only a specific catalog can use a v5 policy and that it cannot be advertised as a gateway service-level user policy. This property is valid only if the file type is `policy-v5`. By using this property, you can define the policy once and share it across all catalogs, eliminating the need for manifest updates when adding the policy to new catalogs. This property requires that the policy implementation remains unchanged across catalogs. Note: The `catalog-scoped` property in `v5_policy` is an alternative to the existing `catalog` property. You can select either `catalog-scoped` or `catalog`, can never use both simultaneously.

Example `manifest.json`

The following example `manifest.json` file enables v5 policy emulation and specifies two built-in v5 policies to deploy. The files section lists two v5 policy implementation files and two extension files.

```
{
   "extension":{
      "properties":{
         "deploy-policy-emulator":true,
         "deploy-policies":[
            "invoke_1.5.0"
         ]
      },
      "files":[
         {
            "filename":"proxy_service.zip",
            "deploy":"immediate",
            "type":"dp-import"
         },
         {
            "filename":"add_udp.zip",
            "deploy":"deferred",
            "type":"extension"
         },
         {
            "filename":"override-parse-defaults.json",
            "type":"gwd_extension"
         },
         {
            "filename":"jws-sign-policy.zip",
            "deploy":"immediate",
            "type":"policy-v5"
         },
         {
            "filename":"jwe-decrypt-policy.zip",
            "deploy":"deferred",
            "type":"policy-v5",
            "catalog":"extension-org_ext-cat-2"
         },
         {
            "filename":"mypolicy.zip",
            "deploy":"immediate",
            "type":"user-defined-policy"
         },
         {
            "filename":"Invoke-Private-Backend-policy.yaml",
            "deploy":"immediate",
            "type":"user-defined-policy-yaml"
         }
      ]
   }
}
```

- **CLI command file extensions**
  Extend DataPower API Gateway behavior with CLI commands in .cfg files.

GWD extension type

The `gwd_extension` type is a JSON map that is used to apply user customizations to objects generated by the gateway service.

The `gwd_extension` map contains an array of user-defined CLI commands to be run on one or more objects. Only one `gwd_extension` is allowed in the manifest. When deployment is set to deferred, restarting the API Connect gateway service object is required to apply, update, or remove the overrides.

Key features of the `gwd_extension` type:

- The `gwd_extension` type can be used to define overrides at various scope-levels, which means a single array of override commands can be applied to one or more objects of a particular type.
- With some object mappings, you can define instances within a scope so that you can apply the custom CLI commands to all objects in that scope that match a particular name or criteria. For example, you can apply overrides to all catalog instances with the name `MyCatalog` regardless of which organization it belongs to.
- By default, the overrides are applied in order of scope granularity (global → organization → catalog → product → instance).
- Add `"@exclusive": true` to the object at any scope level to signal not to apply the previous scopes. Similarly, using an empty override array in a scope is a signal to not apply all previous scope overrides for that mapping, see tls-client for an example.

The supported scopes are:

- `_global`: Applies customizations to all objects of a particular type. For example, add one or more custom assembly-rate-limits to all `api-collections`.
  - `_instance`: Applies customizations to all objects that match a name or criteria. For example, add one or more custom `assembly-rate-limits` to all `api-collections` with the name `my-restricted-catalog` regardless which organization it belongs to.
- `_organization`: Applies customizations to all objects used in an organization. For example, apply a customization to all TLS client profiles that are used in the organization called `provorg`.
  - `_instance`: Applies customizations to all objects that match a name or criteria. For example, applying a customization to all TLS client profiles with a particular name and version regardless of which catalog is using it.
- `_catalog`: Applies customizations to all objects used in a catalog. For example, apply a customization to all TLS client profiles used in the catalog `myCat` of organization `myOrg`.
  - `_instance`: Applies customizations to all objects that match a name or criteria. For example, applying a customization to all plans in a catalog with a particular name regardless of which product it comes from.
- `_product`: Applies customizations to all objects of a type used in a product. For example, apply a customization to all plans in `product my-prod:1.0.0` published in catalog `myCat` of organization `myOrg`. The product scope is only used by the api-plan `gwd_extension` extension type.
- `_instance`: Applies customizations to a single instance. For example, apply a customization to TLS client profile `my-profile:1.0.0` in catalog `myCat` of organization `myOrg`.

Example `gwd_extension` that shows multiple types of overrides:

```
{
  "parse-settings":{
     "_global":{
        "override":[
           "document-size 4194304"
        ]
     }
  },
  "apigw":{
     "_global":{
        "override":[
           "assembly-rate-limit ratelimit-reject-ALL 10000 5 second on on on off off off \"\" \"1\"",
           "assembly-rate-limit ratelimit-alert-ALL 7500 5 second off on on off off off \"\" \"1\""
        ]
     }
  }
}
```

The `gwd_extension` type supports the following objects:

- **config-sequence**
  The config-sequence object created by `apic-gw-service`, which is used to create all API gateway objects.
- **parse-settings**
  Parse settings used by the API Gateway.
- **analytics-endpoint**
- **front-side-handler**
  FSH and associated SNI Server profiles and objects that are used by the API Gateway.
- **apigw**
  API Gateway object.
- **tls-client**
- **api-collection**
  Catalog objects.
- **api-plan**
  API Plan objects that are created from published products.
- **registry**
  Registry objects used in a catalog.
- **oauth-provider**
  Oauth objects used in a catalog.
- **api-definition**
  The API objects that are published to one or more catalogs.
- **assembly**
  The assembly objects and their associated actions that are used by APIs and global policies.

config-sequence

The config-sequence object created by `apic-gw-service`, which is used to create all API gateway objects.

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "config-sequence":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

parse-settings

Parse settings used by the API Gateway.

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "parse-settings":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

analytics-endpoint

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "analytics-endpoint":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

front-side-handler

FSH and associated SNI Server profiles and objects that are used by the API Gateway.

- Override Key: `source-https`
- Child Objects:
  - `ssl-sni-server`
  - `ssl-sni-map`
  - `ssl-server`
    - Override Key: profile
    - _instance: SNI hostname key
    - Child Objects:
      - `valcred`
      - `idcred`
- Scopes:
  - _global
- Example:

```
{
   "front-side-handler":{
      "_global":{
         "source-https":[
            "summary global my-fsh-override"
         ],
         "ssl-sni-server":[
            "summary global my-sni-server-override"
         ],
         "ssl-sni-map":[
            "summary global my-sni-map-override"
         ],
         "ssl-server":{
            "_instance":{
               "*.myhost.com":{
                  "profile":[
                     "summary sni-host-instance-my-profile-override"
                  ],
                  "valcred":[
                     "summary sni-host-instance-my-valcred-override"
                  ],
                  "idcred":[
                     "summary sni-host-instance-my-idcread-override"
                  ]
               }
            },
            "profile":[
               "summary my-profile-override"
            ],
            "valcred":[
               "summary my-valcred-override"
            ],
```

```
            "idcred":[
               "summary my-idcread-override"
            ]
         }
      }
   }
}
```

apigw

API Gateway object.

- Override Key: override
- Scopes:
  - _global
- Example:

```
{
   "apigw":{
      "_global":{
         "override":[
            "summary my-override"
         ]
      }
   }
}
```

tls-client

Profiles that are attached to catalogs.

- Override Key: profile
- Child Objects:
  - Valcred
  - Idcred
- Scopes:
  - _global
    - _instance: *<profileName>*V*<profileVersion>*
  - _organization
    - _instance: *<profileName>*V*<profileVersion>*
  - _catalog
  - _instance: *<profileName>*V*<profileVersion>*
- Example: In this example, an empty array for **valcred** in catalog scope is used. The use of any empty array means the **valcreds** for TLS profiles in that catalog do not get the global or organizational overrides.

```
{
   "tls-client":{
      "_global":{
         "_instance":{
            "my-profileV1.0.0":{
               "profile":[
                  "summary global-instance-profile-override"
               ],
               "valcred":[
                  "summary global-instance-valcred-override"
               ],
               "idcred":[
                  "summary global-instance-idcred-override"
               ]
            }
         },
         "profile":[
            "summary global-profile-override"
         ],
         "valcred":[
            "summary global-valcred-override"
         ],
         "idcred":[
            "summary global-valcred-override"
         ]
      },
      "_organization":{
         "my-org":{
            "profile":[
               "summary org-profile-override"
            ]
         }
      },
      "_catalog":{
         "my-org":{
            "my-catalog":{
               "profile":[
                  "summary cat-profile-override"
               ],
               "valcred":[
```

```
            ]
         }
      }
   },
   "_instance":{
      "my-org":{
         "my-catalog":{
            "my-tlsV1.0.0":{
               "profile":[
                  "summary instance-profile-override"
               ],
               "valcred":[
                  "summary instance-valcred-override"
               ]
            }
         }
      }
   }
}
```

api-collection

Catalog objects.

- Override Key: collection
- Child Objects:
  - `preflow-assembly-function`
  - `preflow-assembly-function-call`
  - `postflow-assembly-function`
  - `postflow-assembly-function-call`
  - `global-assembly-rule`
  - `global-assembly`
  - `global-assembly-function`
  - `global-assembly-function-call`
  - `assembly-function-rule`
- Scopes:
  - _global
    - _instance: *<catalogName>*
  - _organization
  - _catalog
- Example: In the example, global instance is used to apply override to all `api-collections` that have the name `my-catalog`, regardless of what organization they belong to.

```
{
   "api-collection":{
      "_global":{
         "_instance":{
            "my-catalog":{
               "collection":[
                  "summary hello my-catalog"
               ]
            }
         },
         "preflow-assembly-function":[
            "summary hello preflow-assembly-function global scope"
         ],
         "preflow-assembly-function-call":[
            "summary hello preflow-assembly-function-call global scope"
         ],
         "postflow-assembly-function":[
            "summary hello postflow-assembly-function global scope"
         ],
         "postflow-assembly-function-call":[
            "summary hello postflow-assembly-function-call global scope"
         ],
         "global-assembly-rule":[
            "summary hello global-assembly-rule global scope"
         ],
         "global-assembly":[
            "summary hello global-assembly global scope"
         ],
         "global-assembly-function":[
            "summary hello global-assembly-function global scope"
         ],
         "global-assembly-function-call":[
            "summary hello global-assembly-function-call global scope"
         ],
         "assembly-function-rule":[
            "summary hello assembly-function-rule global scope"
         ],
         "collection":[
            "summary hello collection global scope"
         ]
      },
      "_organization":{
         "my-org":{
```

```
            "collection":[
               "summary hello collection org scope"
            ]
         }
      },
      "_catalog":{
         "my-org":{
            "my-catalog":{
               "collection":[
                  "summary hello collection cat scope"
               ]
            }
         }
      }
   }
}
```

api-plan

API Plan objects that are created from published products.

- Override Key: override
- Child Objects:
  - `graphql-schema-options`
    - Override Key: override
    - Child Objects:
      - `visibility-list`
  - `rate-limit`
    - Child Object:
      - `rate-limit-definition`
        - Override Key: override
  - `burst-limit`
    - Child Object:
      - `rate-limit-definition`
        - Override Key: override
  - `rate-limit-group`
    - Override Key: override
  - `api-operation-rate-limit`
    - Override Key: override
    - Child Objects:
      - `rate-limit-group`
      - `rate-limit-definition`
  - `assembly-limit`
    - Child Objects:
      - `rate-limit`
      - `burst-limit`
      - `count-limit`
- Scopes:
  - global
    - _instance: *<planName>*.
  - organization
    - _instance: *<planName>*.
  - catalog
    - _instance: *<planName>*.
  - product: *<name>*:*<version>*
  - _instance: *<planName>*.
- Example:

```
{
   "api-plan":{
      "_global":{
         "graphql-schema-options":{
            "visibility-list":[
               "echo hello graphql-schema-options visibility _global"
            ],
            "override":[
               "echo hello graphql-schema-options _global"
            ]
         },
         "rate-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello rate-limit _global"
               ]
            }
         },
         "burst-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello burst-limit _global"
               ]
            }
         },
         "rate-limit-group":{
            "override":[
```

```
            "echo hello rate-limit-group _global"
         ]
      },
      "api-operation-rate-limit":{
         "rate-limit-definition":{
            "override":[
               "echo hello api-operation-rate-limit _global"
            ]
         },
         "rate-limit-group":{
            "override":[
               "echo hello api-operation-rate-limit-group _global"
            ]
         },
         "override":[
            "echo hello api-operation-rate-limit _global"
         ]
      },
      "assembly-limit":{
         "rate-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello assemby rate-limit _global"
               ]
            }
         },
         "burst-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello assebmly burst-limit _global"
               ]
            }
         },
         "count-limit":{
            "rate-limit-definition":{
               "override":[
                  "echo hello assebmly count-limit _global"
               ]
            }
         }
      },
      "override":[
         "echo hello api-plan _global"
      ]
   },
   "_organization":{
      "my-org":{
         "override":[
            "summary hello api-plan _organization"
         ]
      }
   },
   "_catalog":{
      "my-org":{
         "my-catalog":{
            "override":[
               "summary hello api-plan _catalog"
            ]
         }
      }
   },
   "_product":{
      "my-org-2":{
         "my-cat-2":{
            "my-product:1.0.0":{
               "override":[
                  "summary hello api-plan _product"
               ]
            }
         }
      }
   },
   "_instance":{
      "my-org3":{
         "my-catalog-3":{
            "my-product:1.0.0":{
               "my-plan-1":{
                  "override":[
                     "summary hello api-plan _instance"
                  ]
               }
            }
         }
      }
   }
}
```

registry

Registry objects used in a catalog.

- Registry types:
  - LDAP
    - Override Key: override
    - Child object: **`ldap-search-parameters`**
  - AuthUrl
    - Override Key: override
- Scopes:
  - _global
  - _organization
  - _catalog
  - _instance: APIM name
- Example:

```
{
   "registry":{
      "ldap":{
         "_global":{
            "override":[
               "ldap-readtimeout 120"
            ],
            "ldap-search-parameters":[
               "summary override parameters global"
            ],
            "_instance":{
               "my-ldap-registry":{
                  "ldap-search-parameters":[
                     "summary override parameters global instance"
                  ],
                  "override":[
                     "ldap-port 636",
                     "ssl-client ldap-ssl-client"
                  ]
               }
            }
         },
         "_organization":{
            "my-org":{
               "override":[

               ],
               "_instance":{
                  "my-ldap-registry":{
                     "override":[
                        "ldap-version v3",
                        "ldap-bind-password mypw",
                        "ldap-search-param ldap-param",
                        "summary override org instance"
                     ]
                  }
               }
            }
         },
         "_catalog":{
            "my-org":{
               "my-catalog":{
                  "override":[
                     "ldap-host 1.2.3.4",
                     "ldap-bind-dn cn=root,dc=datapower,dc=com",
                     "summary override catalog"
                  ]
               }
            }
         },
         "_instance":{
            "my-org-3":{
               "my-catalog-3":{
                  "my-ldap-reg":{
                     "override":[

                     ],
                     "ldap-search-parameters":[

                     ]
                  }
               }
            }
         }
      },
      "authUrl":{
         "_global":{
            "override":[
               "summary override global"
            ],
            "_instance":{
               "httpbin":{
                  "override":[
                     "summary override global instance"
                  ]
               }
            }
         },
         "_organization":{
            "my-org":{
```

```
            "override":[

            ],
            "_instance":{
               "httpbin":{
                  "override":[
                     "summary override org instance"
                  ]

}
```

oauth-provider

Oauth objects used in a catalog.

- Oauth Types
  - Native
    - Override Key: override
  - Third-party
    - Override Key: override
- Scopes:
  - _global
    - _instance: APIM name
  - _organization
    - _instance: APIM name
  - _catalog
  - _instance: APIM name
- Example

```
{
   "oauth-provider":{
      "native":{
         "_global":{
            "override":[
               "apic-access-token-ttl 86400"
            ],
            "_instance":{
               "my-native-oauth":{
                  "override":[
                     "scopes-allowed cmcscope1",
                     "enable-debug-mode on"
                  ]
               }
            }
         },
         "_organization":{
            "my-org-2":{
               "override":[

               ]
            }
         },
         "_instance":{
            "my-org":{
               "my-catalog":{
                  "my-native-oauth-2":{
```

```
                    "override":[
                       "apic-enable-introspection on",
                       "apic-auth-code-ttl 600",
                       "apic-enable-refresh-token on "
                    ]
                 }
              }
           }
        }
     },
     "third-party":{
        "_organization":{
           "my-org":{
              "_instance":{
                 "my-third-party-oauth":{
                    "override":[
                       "third-party-introspect-url https://someaddress.com"
                    ]
                 }
              }
           }
        }
     }
  }
```

api-definition

The API objects that are published to one or more catalogs.

- Override Key: api-definition
- Child Objects
  - api-schema
  - Security-definition
    - oauth2
      - api-sec-oauth
      - _instance: swagger name
    - apiKey
      - api-sec-apikey
      - _instance: swagger name
    - http
      - api-sec-http-scheme
      - _instance: swagger name
    - basic
      - x-ibm-authentication-url
      - api-sec-basic-auth
      - _instance: swagger name
  - security-requirements
    - api-sec-oauth-req
      - Override Key: override
      - _instance: Datapower object name
    - api-sec-req
  - api-path
    - Override Key: path
    - _instance: *<Path URI>*
    - Child Objects
      - api-operation
        - Override Key: operation
        - _instance: *<Operation Method>*
        - Child Objects
          - security-requirement
            - api-sec-oauth-req
              - Override Key: override
              - _instance: Datapower object name
            - api-sec-req
          - api-schema-request
          - api-schema-response
            - Override Key: override
            - _instance: Datapower object name
        - api-schema-request
  - wsdl-validation-schema-location
  - cors-policy
  - cors-rule
    - Override Key: override
    - _instance: Datapower object name
- Scopes:
  - _global
    - _instance: name:version
  - _organization
    - _instance: name:version
  - _catalog

- _instance: name:version

- Example: In this example, the `@exclusive` flag is used on the instance nick-limits:1.0.0 in my-catalog of my-organization. The `@exclusive` flag means that only the CLI commands at the instance level are applied for that API while all other APIs in that catalog still have the global, organization, and catalog CLI commands applied to them.

        - _instance: Error Name
    - default
    - finally
- Scopes:
    - _global
        - _instance: swagger name:version
    - _organization
        - _instance: swagger name:version
    - _catalog
    - _instance: swagger name:version
- Example: In this example, 2 instances are included within the global scope mapping. First is, **`my-global-policy:1.0.0`**, which is a global-policy that is used in some catalogs. Since it is defined at the global scope, the overrides apply anytime an assembly is built from a swagger with the name and version of **`my-global-policy:1.0.0`**. Second is, **`complex-switch:1.0.0`**, which is an API that is published to various catalogs. Similarly, since it is defined as an instance with in the global scope the overrides apply anytime that the assembly is built from a swagger with the name and version of **`complex-switch:1.0.0`**. Also see the **`set-var`** example within global scope for an example of overriding assembly action instances based on the title that is given in APIM or the DataPower object name.

            "my-catalog":{
               "api-rule":[
                  "echo hello rule _catalog scope"
               ],
               "assembly":[
                  "echo hello assembly _catalog scope"
               ],
               "assembly-actions":{
                  "if":{
                     "api-rule":[
                        "echo hello if api-rule _catalog scope"
                     ],
                     "assembly-switch":[
                        "echo hello if assembly-switch _catalog scope"
                     ]
                  }
               }
            }
         }
      },
      "_instance":{
         "my-organization":{
            "my-catalog":{
               "complex-switch:1.0.0":{
                  "api-rule":[
                     "echo hello rule _instance scope"
                  ],
                  "assembly":[
                     "echo hello assembly _instance scope"
                  ],
                  "assembly-actions":{
                     "invoke":{
                        "override":[
                           "echo hello invoke _instance scope"
                        ]
                     }
                  }
               }
            }
         }
      }
   }
}
```

CLI command file extensions

Extend DataPower® API Gateway behavior with CLI commands in .cfg files.

You apply an extension to a DataPower API Gateway by uploading one or more .cfg files that define the required extension behavior. These .cfg files contain DataPower API Gateway CLI commands. For details of the full set of CLI commands that are available, see the DataPower API Gateway CLI command documentation.

You package the .cfg files in a .zip file, together with any additional required files that are referenced from CLI commands; for example, a .json file that contains the OpenAPI definition for an API. The .cfg files are processed in alphanumeric order by file name.
Note:

- All the .cfg files must be at the root of the .zip file. If you are attempting to use an API Connect Version 2018 gateway extension that has files in sub-directories, see Gateway extensions manifest for information on how to deploy multiple extensions in a single package.
- On macOS, run the **zip** command on the command line with the following flags:

  ```
  -x ".DS_Store" -x "__MACOSX"
  ```

  Including the flags prevents the auto-generated .DS_Store and __MACOSX files from being added to the zip.

You upload the extension .zip file to an API Connect Gateway service, and enable the extension, as described in Configuring your Gateway server extensions. Gateway server extensions can be deployed without having to restart the DataPower API Gateway.

To control how gateway extensions are applied to the DataPower API Gateway, you can include a Gateway extensions manifest as a manifest.json file. The manifest allows you to deploy multiple extensions of different types in a single package. For more information, see Gateway extensions manifest.

Using CLI commands in a Gateway extension

Although you can use any DataPower API Gateway CLI commands in your extension .cfg files, typically you use commands that modify API Connect objects that have previously been deployed to the DataPower API Gateway.

When API Connect objects are deployed to a DataPower API Gateway, .cfg are created on the Gateway that define the configuration of those objects. By examining those .cfg on the Gateway, you can determine the precise names of API Connect objects that you want to modify, and the current values of the properties of those objects. You can access these .cfg files by completing the following steps:

1. Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
2. Switch to the DataPower application domain for API Connect if necessary.
3. Under Files and Administration, click File Management.
4. Expand the temporary: folder to locate the .cfg files. The files for API Connect objects are named according to their containing provider organization and Catalog, as follows:

   `20.provider-org-name_catalog-name_collection.cfg`

   The prefix `20` controls the position of the file in the overall processing sequence, which is in alphanumeric order by file name.
   Restriction:
   - Do not modify these files directly in the DataPower API Gateway file system. Instead, use the gateway extension mechanism described on this page.
   - Do not apply gateway extension modifications to configuration in the local:/config-sequence.cfg file.
   - Do not use Gateway server extensions to modify objects that cause the `apic-gw-service` object to restart, such as TLS Profiles, and Gateway Peering. Extensions that cause the `apic-gw-service` object to restart, lead to unpredictable behavior in the Gateway service.

Note: Modifying a .cfg file triggers the execution of all other .cfg files that run commands on the same object.

Config-Sequence tracks all of the objects that it manages through the .cfg files. Any change to a .cfg file that causes config-sequence to run commands on an object automatically executes all other .cfg files that run commands on the same object.

Example: If a new product is published to catalog A, then the .cfg file for that collection in temporary://config will be modified by the apic-gw-service to reflect the new product. Because that .cfg file was changed, config-sequence will execute every other .cfg file that also runs operations on catalog A, in the sequence of locations defined in the config-sequence object. If there are 2 .cfg files in the same location that run commands on catalog A, they run in alphabetical order.

Example 1 - change the scope of the rate limit for a Plan

Suppose the DataPower API Gateway configuration for a Plan has the following CLI command:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
```

The **api-plan** command has the following syntax:

```
api-plan plan_name
```

and creates a Plan of the specified name, or modifies a Plan of the same name if it already exists. By using the specified name, you can add **api-plan** commands in your Gateway extension .cfg files to modify the Plan.
Note: The names of API Connect objects in the DataPower API Gateway configuration are derived from their configuration in API Connect. For example, a Plan name has the following structure:

```
provider-org-name_catalog-name_product-name_product-version_plan-name
```

where:

- *provider-org-name* is the name of the provider organization.
- *catalog-name* is the name of the Catalog in that provider organization.
- *product-name* is the name of the Product that contains the Plan.
- *product-version* is the version of the Product.
- *plan-name* is the name of the Plan.

The default scope to which a Plan rate limit applies is per application. To change this setting on the Plan in this example, so that the rate limit scope is per client ID, add the following command to a .cfg in your Gateway extension:

```
api-plan myorg_sandbox_financial-services_1.0.0_basic
  rate-limit-scope per-client-id
exit
```

For more information on configuring Plans by using DataPower API Gateway CLI commands, see API Plan commands.

Example 2 - add a path to an API definition

The .cfg file in this example performs the following actions:

1. Uses the **top** and **configure terminal** commands to reset CLI processing.
2. Uses the **api-operation** command as follows:
   a. Creates a new operation called `bank_branches_get_operation`.
   b. Uses the **reset** command to set all properties to their default values.
   c. Sets the operation method to `GET`.
3. Uses the **api-path** command as follows:
   a. Creates a new path called `bank_branches_path`.
   b. Uses the **reset** command to set all properties to their default values.
   c. Sets the path URL segment to `/details`.
   d. Adds the previously created operation `bank_branches_get_operation` to the path.
4. Uses the **api-definition** command as follows:
   a. Modifies the existing API definition called `myorg_sandbox_myapi_1.0.0`.

Note: The name of the API definition was derived from its configuration in API Connect when it was published to the DataPower API Gateway, and has the following structure:

```
provider-org-name_catalog-name_api-name_api-version
```

where:

- *provider-org-name* is the name of the provider organization.
- *catalog-name* is the name of the Catalog in that provider organization.
- *api-name* is the name of the API definition in API Connect.
- *api-version* is the version of the API.

b. Adds the previously created path `bank_branches_path` to the API definition.
Note: The **reset** command is not used here because that would reset all the current settings on the `myorg_sandbox_myapi_1.0.0` API definition, whereas the requirement is to add a new path to the existing configuration of the API definition.

The .cfg file is as follows:

```
top; configure terminal

api-operation bank_branches_get_operation
  reset
  method GET
exit

api-path bank_branches_path
  reset
  path "/details"
  operation bank_branches_get_operation
exit

api-definition myorg_sandbox_myapi_1.0.0
  path bank_branches_path
exit
```

For more information on the DataPower API Gateway CLI commands used in this example, see the following pages:

- Initial login and common commands
- API Operation commands
- API Path commands
- API Definition commands

Gateway extension limitations

This section details the limitations of the extensions to the DataPower API Gateway.

- If you use an extension to create a user-defined policy and then delete the extension, the extension cfg's are removed from the filesystem, but the configuration sequence will not remove referenced objects created by the cfg's. For the policy objects to be cleaned up, you must first send an extension update that explicitly removes the user-defined policy from `apic-gw-service`, as in the following example.

  ```
  apic-gw-service
      no user-defined-policies udp-basic_1.0.0
  exit
  ```

  Note: This limitation does not apply only to user-defined policies, but any object customization that adds a reference to another object.
- `user-defined-policy-yaml` policies that use or reference another policy can be deployed only after the referenced policy has been advertised to API Manager. The deploy type must be set to `deferred` and the Gateway Service must be restarted.
- Deleting an extension that is used to create a user-defined policy using a .cfg file does not remove the policy reference in the `apic-gw-service` object. The policy is not removed from the assembly palette until a reboot or restart of the Gateway pod. To properly remove the policy, send an `apic extensions:update` command that explicitly removes the policy from the `apic-gw-service` prior to sending the `apic extensions:delete` command.
- v5 policies that contain files outside of the `/policy` directory are not supported. If multiple v5 policies reference the same file outside the `/policy` directory, the last applied policy will overwrite the file and will be used by all policies that reference it. Removing any policy that contains the file will cause the file to be deleted and may cause errors for the remaining policies that use it.
- If an extension contains or references objects and files that are also referenced by other objects outside of the extension, deleting the extension can cause errors that are difficult to troubleshoot.
- It is possible to delete an extension that is referenced by published APIs. This may cause those API requests to return errors.
- For an extension type of `user-defined-policy`, extra assembly functions may be present in the DataPower import `.zip` file, even if there is no `.yaml` file to indicate their presence. Using these functions without declaring them using a `.yaml` file is not supported. A policy `.yaml` file is required for each policy you want to advertise to API Manager.
- Extension type `user-defined-policy-yaml` may leak generated Gatewayscript `.js` files in temporary:/js/ or `.xslt` files when deleted.
- Extension types that use SOMA imports must use new objects with no overrides. If you override a singleton or shared object using an extension of this type, then the object will not be restored to its previous state when the extension is deleted, and those objects may be missing after the extension is deleted. You must then restore any needed objects.
- During APIM lifecycle events, customization made to objects created by the DataPower API Gateway connect service using CLI command file extensions may be temporarily lost. For this type of customization, use the GWD extension type.

v5 policy emulation limitations

This page details the limitations of v5 policy emulation for the current release.

- The reverse solidus character (\) might be removed from policy property values.

- The source parameter for XSLT and GatewayScript policies is base-64 encoded to preserve escaping. It cannot be easily viewed from the DataPower command line or the DataPower WebGUI.
- Some DataPower service variables (for example, `var://service/mpgw/skip-backside`) might not be applicable in API Gateway, depending on how the variables are used.
- User-defined policies that make any alterations to a DataPower context are not supported.
- Execution of a 1.0.0 policy may fail if a previous 2.0.0 policy updates the `message.body` content type (for example, from XML to JSON, or JSON to XML).
- A proxy 1.5.0 policy can return an incorrect response if it is the last action within a switch `case` or `otherwise` property. The response is parsed. The correct behavior is to not parse the response. To work around this issue, set the `final-action:true` parameter on the proxy.
- Proxy 1.5.0 and invoke 1.5.0 policies do not preserve the `gtid` header.
- The `cache-putpost-response` property is not included in the schema for invoke 1.5.0 and proxy 1.5.0 policies.
- Setting HTTP response headers in a v5 user-defined policy, GatewayScript policy, or XSLT policy is not supported.
- Non-UTF-8 characters are not supported.
- JSON data returned in the response of an API running in v10 with v5 emulation is formatted without spaces.
- The v5 user-defined policy emulation feature creates v5 compatible context. After running the user-defined policy, the emulation feature analyzes the context and converts it back to DataPower® API Gateway compatible context. The computations involved in this process might negatively impact the DataPower API Gateway performance. For better performance, use a non-emulated user-defined policy. For more information, see Authoring Policies for DataPower API Gateway.
- In the V5E framework, the maximum file size for parsing XML data is 4194304 bytes. Currently, users cannot modify parse settings for GatewayScript.
- API Gateway doesn't have XML Manager. Thus, all configuration set in XML Manager in v5 doesn't take effect in v5e.

Configuring your Gateway server extensions

You can add extra DataPower enforcement capabilities to a gateway service by uploading a .zip file that defines the required extension behavior, and then enabling the extension in DataPower.

About this task

You can upload a Gateway server extension to a Gateway service in either of the following ways:

- Use the Cloud Manager user interface
- Use the developer toolkit CLI

Procedure

- To upload a Gateway server extension to a Gateway service by using the Cloud Manager user interface, complete the following steps:
  1. In the Cloud Manager user interface, click  Topology.
  2. Alongside the required Gateway service, click the options icon ⋮, then click Configure gateway extension.
  3. Click Add.
     Note: You cannot upload more than one Gateway extension .zip file to the same Gateway service. If a Gateway server extension has previously been uploaded, the Add button is not available; you can replace the previous extension by clicking the options icon ⋮ alongside gateway-extension, then clicking Edit.
  4. Upload the extension as indicated, either by dragging and dropping the .zip file, or by browsing and selecting it.
  5. Click Save when done.
- To upload a Gateway server extension by using the developer toolkit CLI, complete the following steps:
  1. Log in to your API Connect Cloud Manager server as an administrator, using the following command:

     ```
     apic login --server <cloud-manager_endpoint_url> --username <admin_user_ID> --password <admin_password> --realm admin/<identity_provider>
     ```

     where:
     - *<cloud-manager_endpoint_url>* is the Cloud Manager endpoint URL; for example: `mgmt-admin.<myserver>.com`.
     - *<admin_user_ID>* is the user ID of your administrator account, and is the same as the user ID that you use to log in to the Cloud Manager user interface.
     - *<admin_password>* is the password for your administrator account.
     - *<identity_provider>* is the identity provider that is used to authenticate administrative users.

     For example:

     ```
     apic login --server mgmt-admin.myserver.com --username admin --password my-admin-password --realm admin/myldap
     ```

  2. Upload the Gateway extension .zip file by using the following command:

     ```
     apic gateway-extensions:create <extension_zip_file> --scope org --org admin --gateway-service <gateway_service> --availability-zone <availability-zone> --server <cloud-manager_endpoint_url>
     ```

     where:
     - *<extension_zip_file>* is the Gateway extension .zip file that you want to upload.
     - *<gateway_service>* is the name of the Gateway service that you want add the extension to.
     - *<availability-zone>* is the name of the availability zone that contains the Gateway service.
     - *<cloud-manager_endpoint_url>* is the Cloud Manager endpoint URL.

     For example:

     ```
     apic gateway-extensions:create myextension.zip --scope org --org admin --gateway-service mygatewayservice --availability-zone availability-zone-default --server mgt-admin.myserver.com
     ```

     This example uses the default supplied availability zone name of `availability-zone-default`, which will be the required value if you have not configured your own availability zones. To check the names of the currently configured availability zones, use the following command:

     ```
     apic availability-zones:list --org admin --server <cloud-manager_endpoint_url>
     ```

     For details on configuring availability zones, see Creating an availability zone.

To check the names of the currently configured gateway services, use the following command:

```
apic gateway-services:list --org admin --availability-zone <availability-zone> --server <cloud-manager_endpoint_url>
```

You can confirm that the extension has been added to the Gateway service by using the `gateway-extensions:get` command; for example:

```
apic gateway-extensions:get --scope org --org admin --gateway-service mygatewayservice --availability-zone
availability-zone-default --server mgt-admin.myserver.com --output -
```

(the parameter setting `--output -` writes the details of the Gateway extension object to the command window. You can specify the name of an existing folder to have the details written to a `.yaml` file in that folder.)
For reference details of the `apic gateway-extensions` commands, see the toolkit CLI reference documentation.

Note: You cannot upload more than one Gateway extension .zip file to the same Gateway service. If you want add further extensions later, update the original .zip file, then use the `apic gateway-extensions:update` command to replace the previous gateway extensions file with the revised one; for example:

```
apic gateway-extensions:update mynewextension.zip --scope org --org admin --gateway-service mygatewayservice --
availability-zone myavailabilityzone --server mgt-admin.myserver.com
```

3. Apply the extension to each server by restarting the API Connect gateway service object; complete the following steps on **each** Gateway server in the Gateway service:
   Note: In Kubernetes environments, the following steps can be accomplished by issuing `kubectl delete pod` on **each** gateway pod. Be sure to wait until each pod gets back to the ready state before deleting the next gateway pod.
   a. Remove the Gateway server from the load balancing group.
   b. Disable, then enable the API Connect gateway service object. You can do this by using either the DataPower® administrative user interface in a web browser, or by using the DataPower CLI.
      - By using the administrative user interface:
        - Log in to the DataPower administrative user interface; for the Graphical Interface, select WebGUI rather than Blueprint Console.
        - Switch to the DataPower application domain for API Connect if necessary.
        - Search for `Gateway Service`.
        - Set the Administrative State to disabled.
        - Apply the changes.
        - Set the Administrative State to enabled.
        - Apply the changes.
      - By using the CLI:
        - Enter configuration mode by entering the command `configure`.
        - Navigate to the DataPower application domain for API Connect by entering the command `switch api_connect_domain_name`, where *api_connect_domain_name* is the name of your API Connect application domain.
        - Disable the API Connect gateway service object by entering the following command:

          ```
          apic-gw-service; admin-state disabled; exit
          ```

        - Enable the API Connect gateway service object by entering the following command:

          ```
          apic-gw-service; admin-state enabled; exit
          ```

   c. Ensure that the gateway service object initialization has completed.
   d. Re-add the Gateway server to the load balancing group.
4. Apply the extension to each server by restarting the API Connect gateway service object; complete the following steps on **each** Gateway server in the Gateway service:
   Note: In Kubernetes environments, the following steps can be accomplished by issuing `kubectl delete pod` on **each** gateway pod. Be sure to wait until each pod gets back to the ready state before deleting the next gateway pod.

Results

The extension is uploaded and applied to each of the servers in the Gateway service, and the associated enforcement capabilities are applied to all incoming API resource requests.

Warning: DataPower Gateway (v5 compatible) only If you upload an extension to the DataPower Gateway (v5 compatible), a status file called extension_import_response.xml is written to the local:/ext folder in the gateway file system. Do not remove this file, otherwise if your gateway extension is subsequently removed then the referenced objects cannot be reverted to their original state automatically, and you will therefore have to either complete these clean up tasks manually, or re-add the gateway extension to regenerate the extension_import_response.xml file and then remove the gateway extension again. If the extension_import_response.xml exists and there is a cleanup failure for any object, a failure file is written to the local:/ext folder, with the failure details.

Cloud Manager Tutorials

Tutorials for using the Cloud Manager user interface in IBM® API Connect.

Prerequisites

To complete the following tutorials you must be the Cloud Administrator or Cloud Owner of an API Connect instance.

Overview

These tutorials guide you through common tasks performed to set up and maintain the configuration of a cloud.

- **Tutorial: Configuring the Cloud**
  This tutorial shows you how to create a basic cloud configuration, with DataPower gateway, event gateway, analytics, and developer portal services.

- **Tutorial: Creating a Provider Organization**
  This tutorial shows you how to create a Provider Organization.

Tutorial: Configuring the Cloud

This tutorial shows you how to create a basic cloud configuration, with DataPower gateway, event gateway, analytics, and developer portal services.

Before You Begin

One of the following roles is required to register and manage services in Cloud Manager:

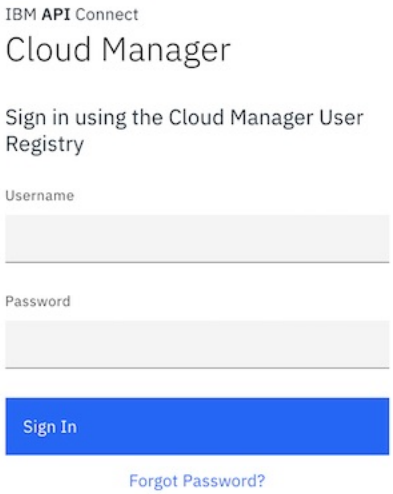
- Administrator
- Topology Administrator
- Owner
- A custom role with the **`Topology:Manage`** permission

You will need the following information to complete this tutorial.

- The IP address or FQDN of the DataPower gateway, and the port assigned to accept API requests from clients.
- The IP address or FQDN of the DataPower gateway, and the port assigned to communicate with the management server. This cannot be the same as the port for API requests.
- The FQDN of the management endpoint on the event gateway to communicate with the API Connect management server.
- The FQDN of the client endpoint on the event gateway, and the port (**`443`**) assigned to accept API requests from clients.
- The FQDN of the developer portal service to accept requests from clients.
- The FQDN of the developer portal to communicate with the management server.
- The FQDN of the analytics service to accept requests from clients.
- The address, port, and optional login credentials for an SMTP email server.

Note: The port for the **`portal-www`**, **`portal-admin`**, and **`analytics-ingestion`** services is **`443`**, and is not configurable.

About this tutorial



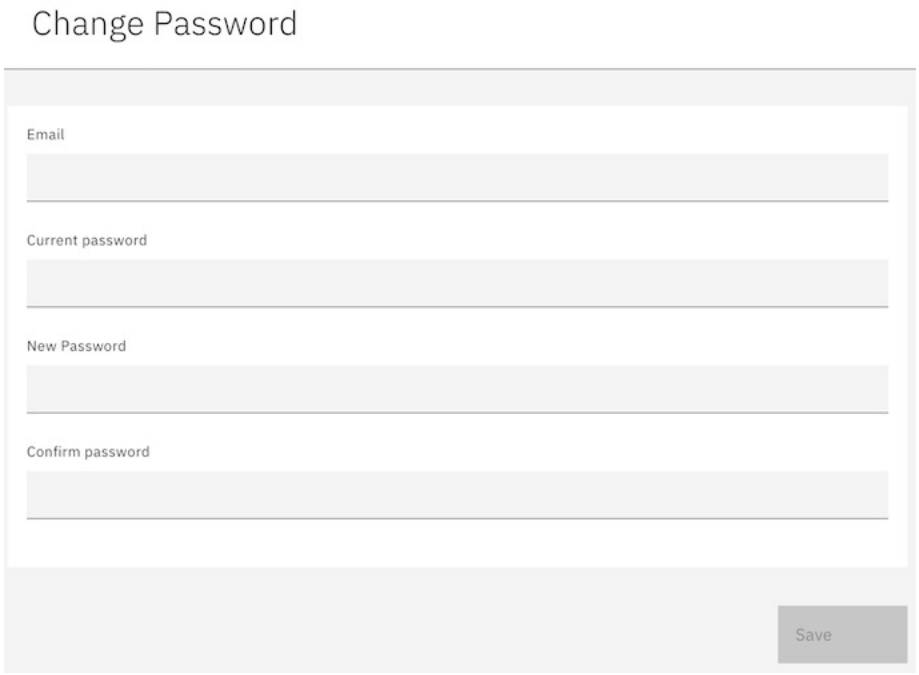
In this tutorial, you will complete the following lessons:

- Initial Cloud Manager Console login
- Configure an Email Server
- Register a DataPower Gateway Service
- Register an Event Gateway Service
- Register a Portal Service
- Register an Analytics Service
- Configure a Default DataPower Gateway Service

Initial Cloud Manager Console login

Take the following steps to log in to the Cloud Manager user interface for the first time.

1. In a web browser, enter the management service URL. For example, `https://ManagementService.domain/admin` where ManagementService.domain is the fully qualified host name or IP address of the Management service.



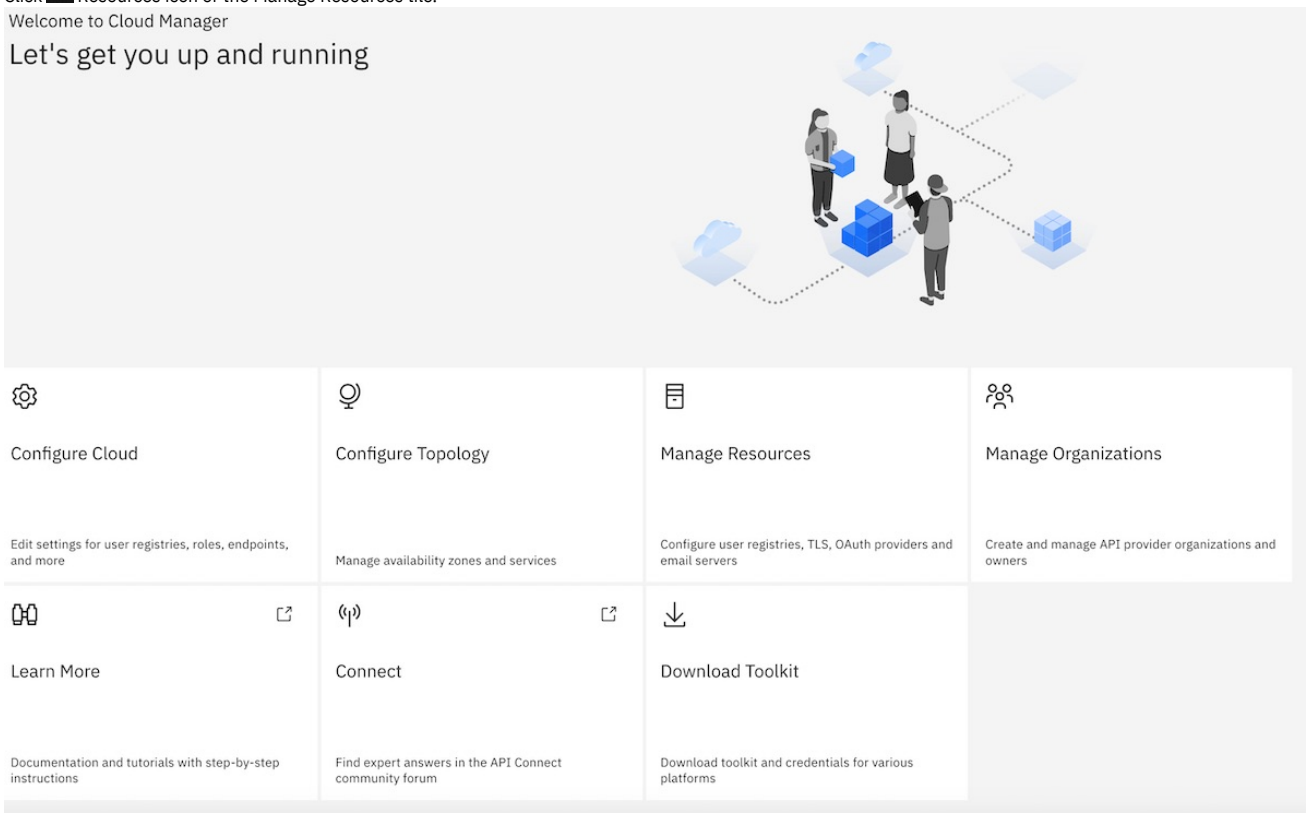
2. Enter the Cloud Administrator user name and password. The default values are `admin` for the user name and `7iron-hide` for the password.

   OpenShift top-level CR install

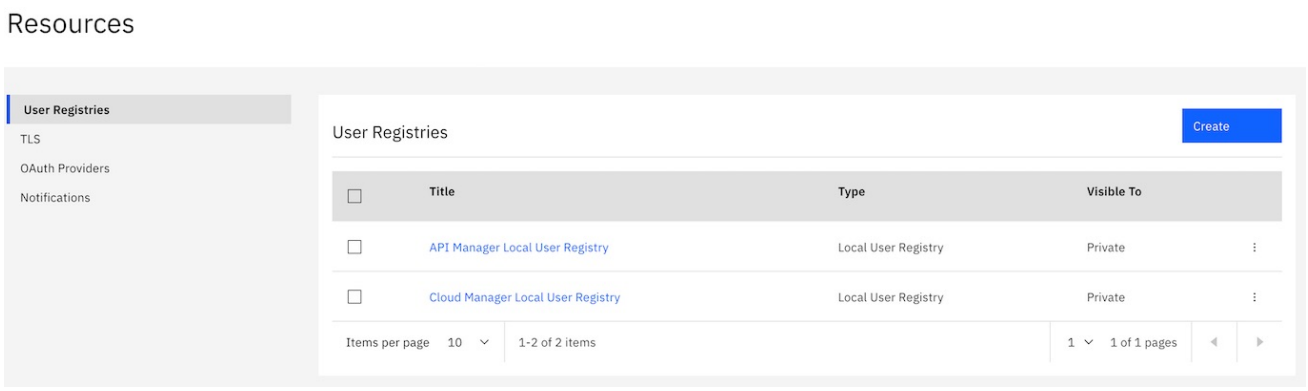
   If you installed API Connect on OpenShift using the top-level "API Connect Cluster" CR, the default user name is `admin`. If you are logging in for the first time, run the following commands to retrieve the initial password, which is generated automatically during deployment:

```
oc get secret -n <namespace> | grep mgmt-admin-pass
oc get secret -n <namespace> <secret_name_from_previous command> -o jsonpath="{.data.password}" | base64 -d && echo ""
```

3. You are immediately required to change the admin password, as well as provide an email address for the cloud administrator. Enter the necessary information. Note: If you forget your password and request a password reset, the notification email is sent to this email address. This action will use the email server set in the Notifications section of the cloud Settings. This tutorial shows you how to set this configuration.

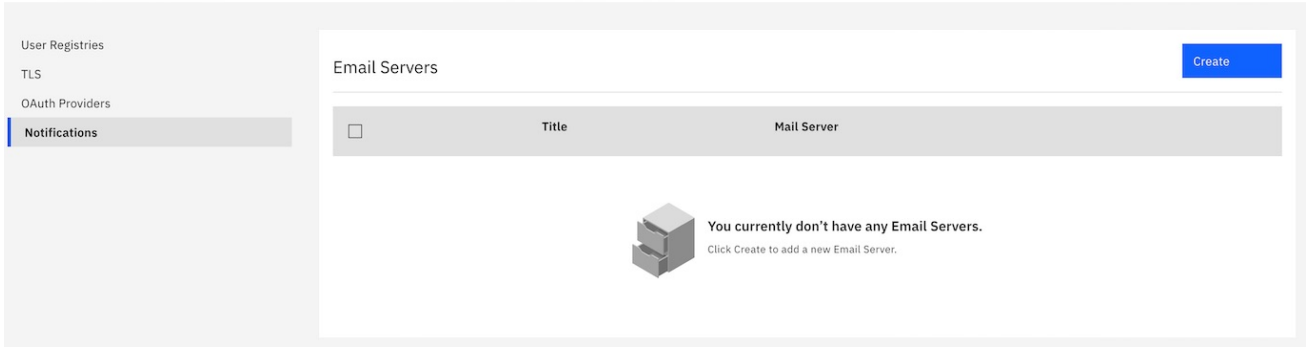


4. Click Save.
5. Log in using the new password.

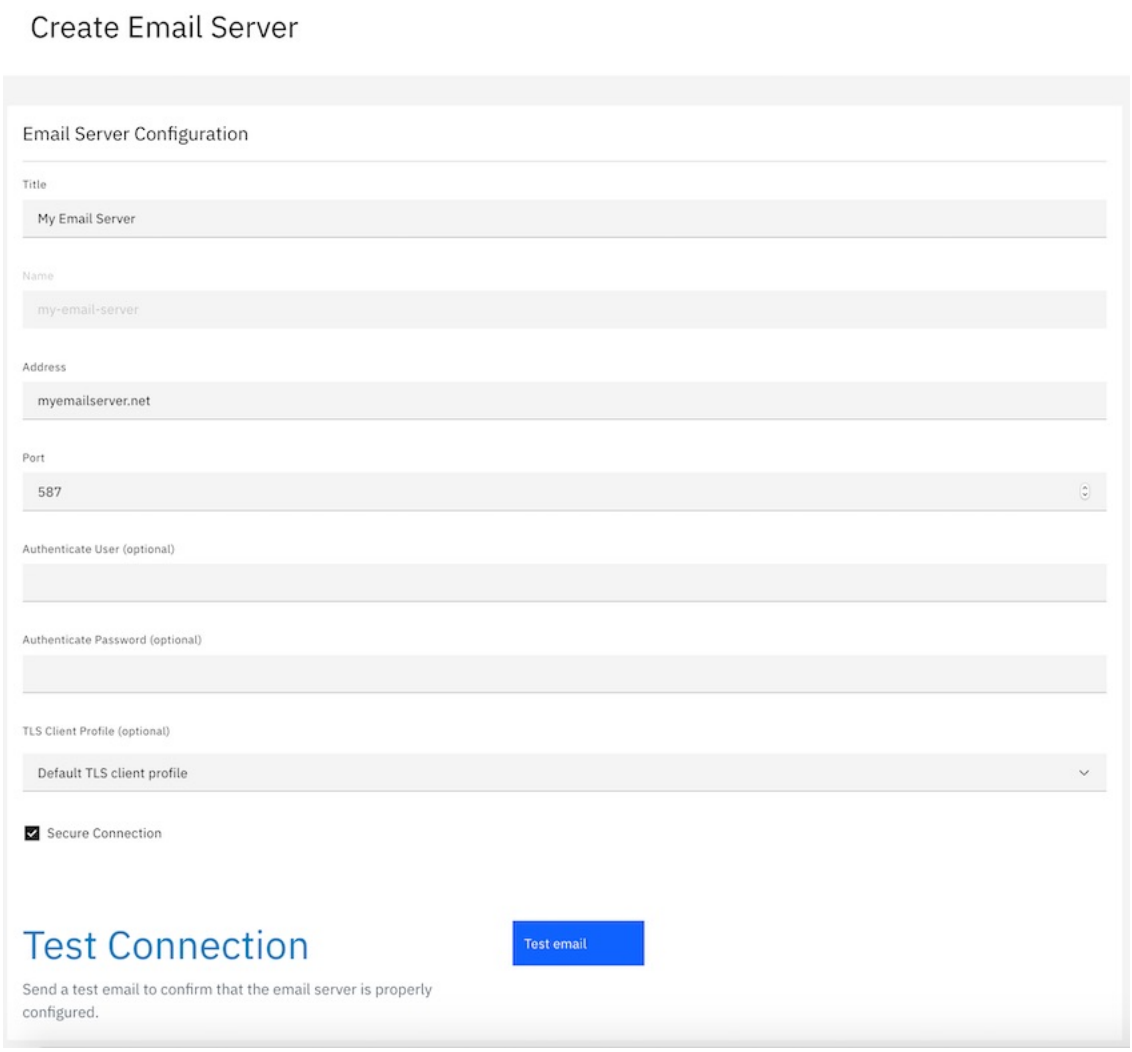


Configure an Email Server

Take the following steps to configure an email server. This configuration allows you to recover the admin password or receive other important notifications.



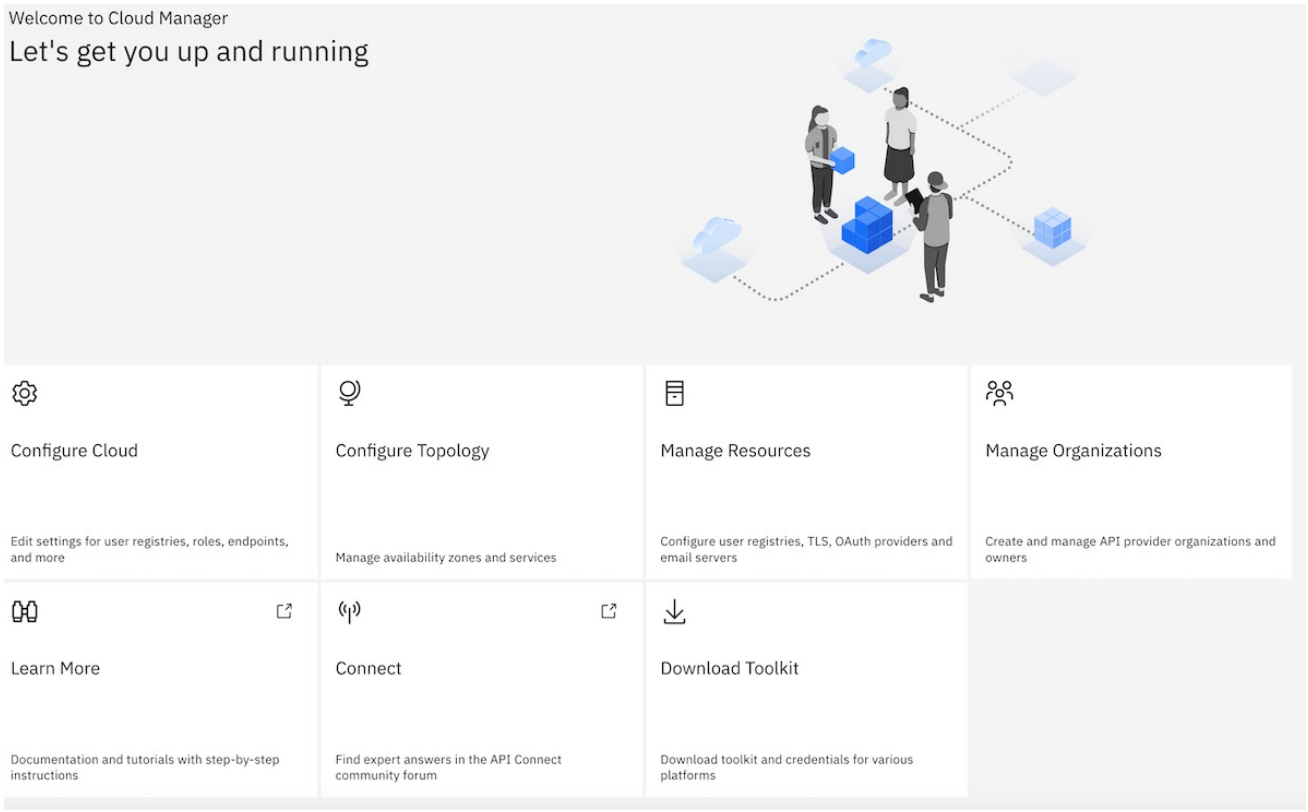
1. Click Resources icon or the Manage Resources tile.



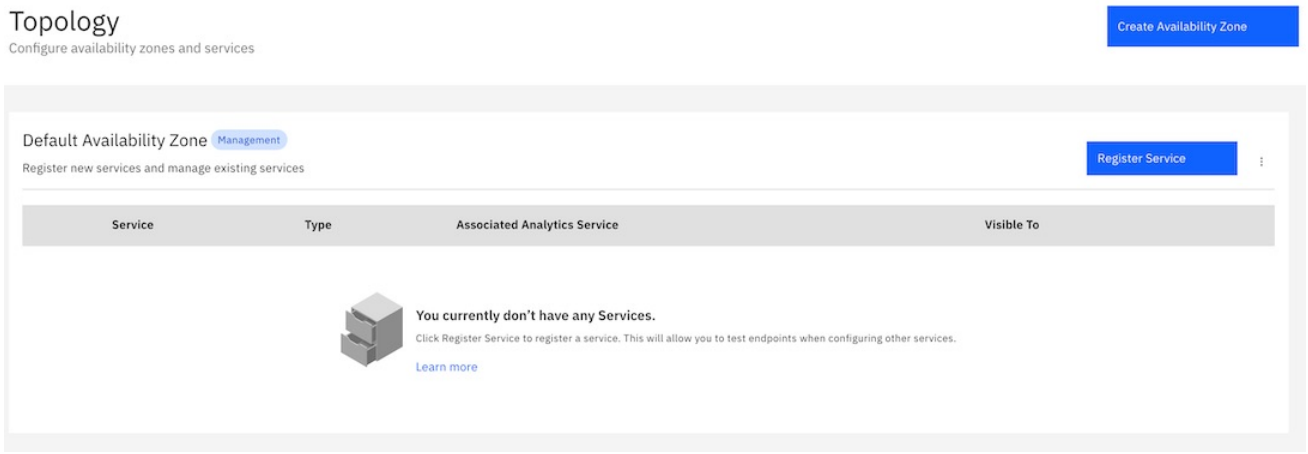
2. Click Notifications.

3. Click Create.

4. Enter the appropriate values in the fields These values vary depending on your site.
5. Click Save.

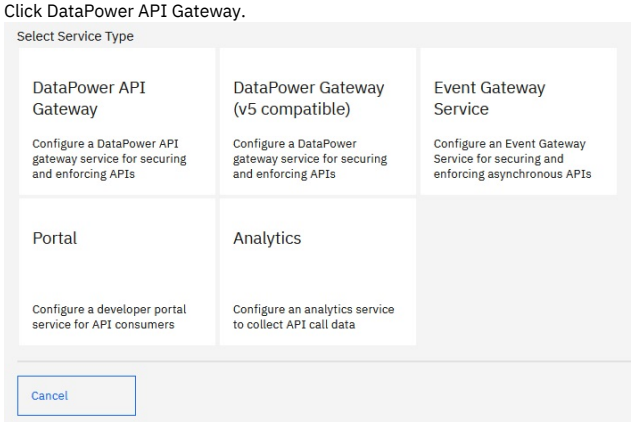


6. Click the Settings icon, then click Notifications > Edit.
7. Ensure your email server is selected, then click Save.
8. Click the Home icon.

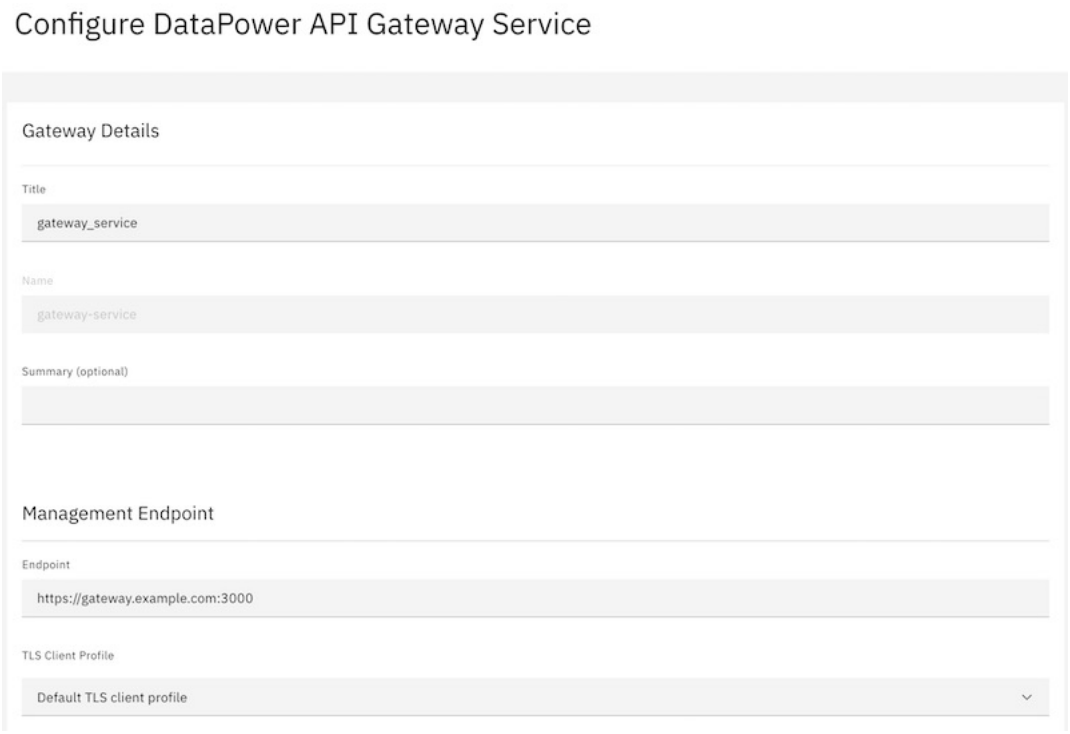


Register a DataPower Gateway Service

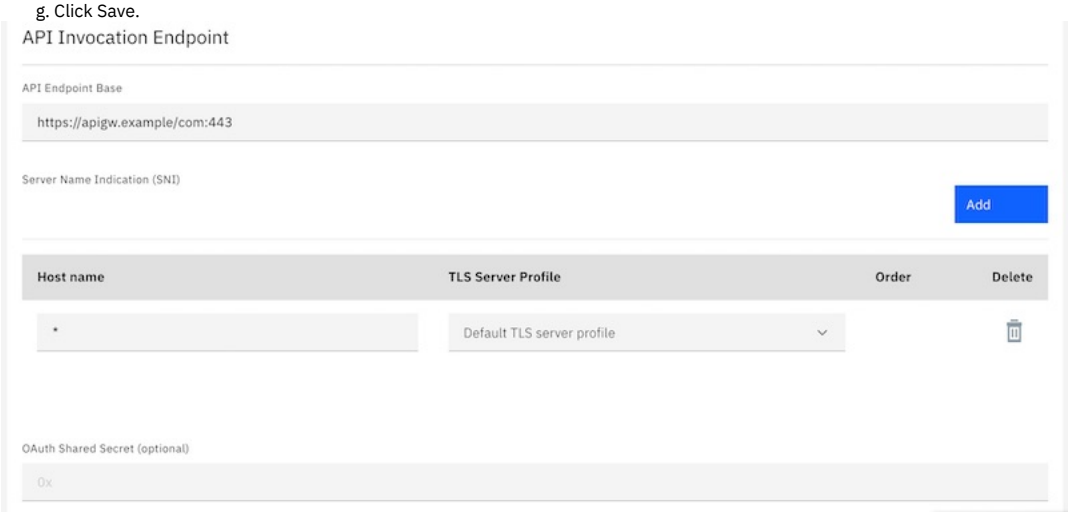
Take the following steps to register a gateway service.



1. Click the Configure Topology tile.

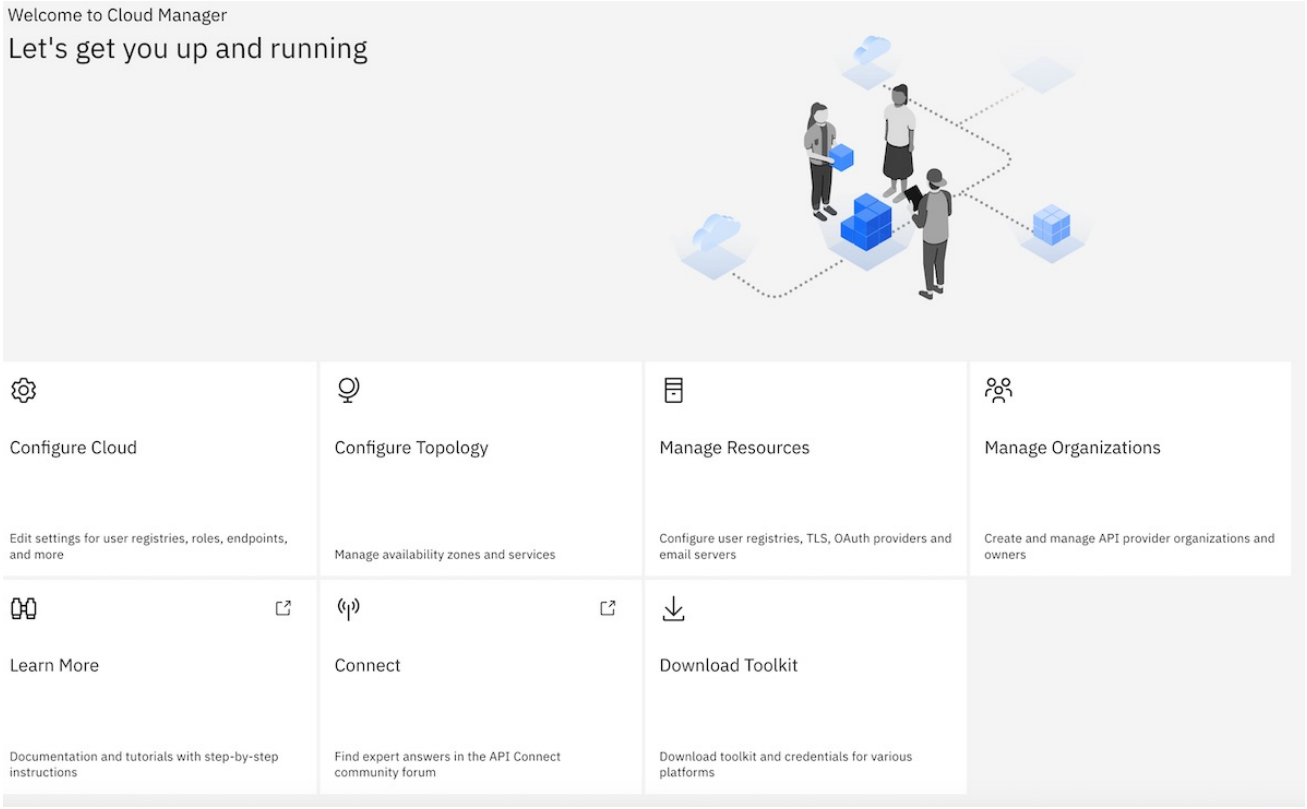


2. Click Register Service.

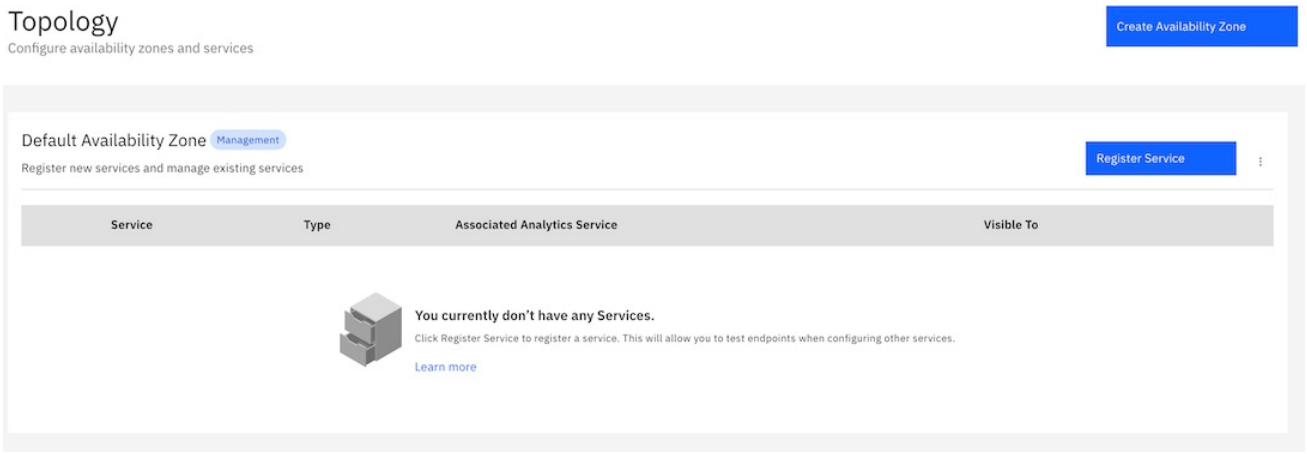


3. Click DataPower API Gateway.

4. Take the following steps.
   a. Enter `gateway_service` in the Title field.
   b. In the Management Endpoint section, enter the URL of the address and port assigned to the management endpoint in the Endpoint field. This is the port used by the API Management server to connect to the gateway.
   c. Leave the remaining values as given to set TLS profiles.



d. In the API Invocation Endpoint section, enter the URL of the gateway address and port assigned to accept API requests from clients in the API Endpoint Base field.
e. Do not change the defaults in the Server Name Indication (SNI) fields unless your topology requires different values.
f. Optionally enter a hex value in the OAuth Shared Secret field. This must be a 64-bit hex value that begins with "0x". Providing a shared secret value here enables gateways in a cluster to read the OAuth tokens generated by any member of the cluster using the same secret.
g. Click Save.



Register an Event Gateway Service

Take the following steps to register an event gateway service.

1. Click the Configure Topology tile.

2. Click Register Service.

3. Click Event Gateway Service.
4. Take the following steps.
   a. Enter `event_gateway_service` in the Title field.
   b. In the Management endpoint on the gateway service field, enter the URL of the event gateway management endpoint.
      To retrieve the URL, complete the following steps:
      i. Log in to your Kubernetes cluster as a cluster administrator by setting your **`kubectl`** context.
      ii. Set the context to the namespace where your Event Endpoint Management instance is installed:

      ```
      kubectl config set-context --current --namespace=<namespace>
      ```

      iii. List the ingress resources and locate the API Connect ingress for your instance; unless overridden, the name ends in **`-apic`**:

      ```
      kubectl get ingress
      ```

      iv. Copy the URL for the ingress resource from the **`Host`** column.
   c. In the API endpoint base field, enter the URL and port of the event gateway client endpoint.
      To retrieve the URL and port, complete the following steps:
      i. Log in to your Kubernetes cluster as a cluster administrator by setting your **`kubectl`** context.
      ii. Set the context to the namespace where your Event Endpoint Management instance is installed:

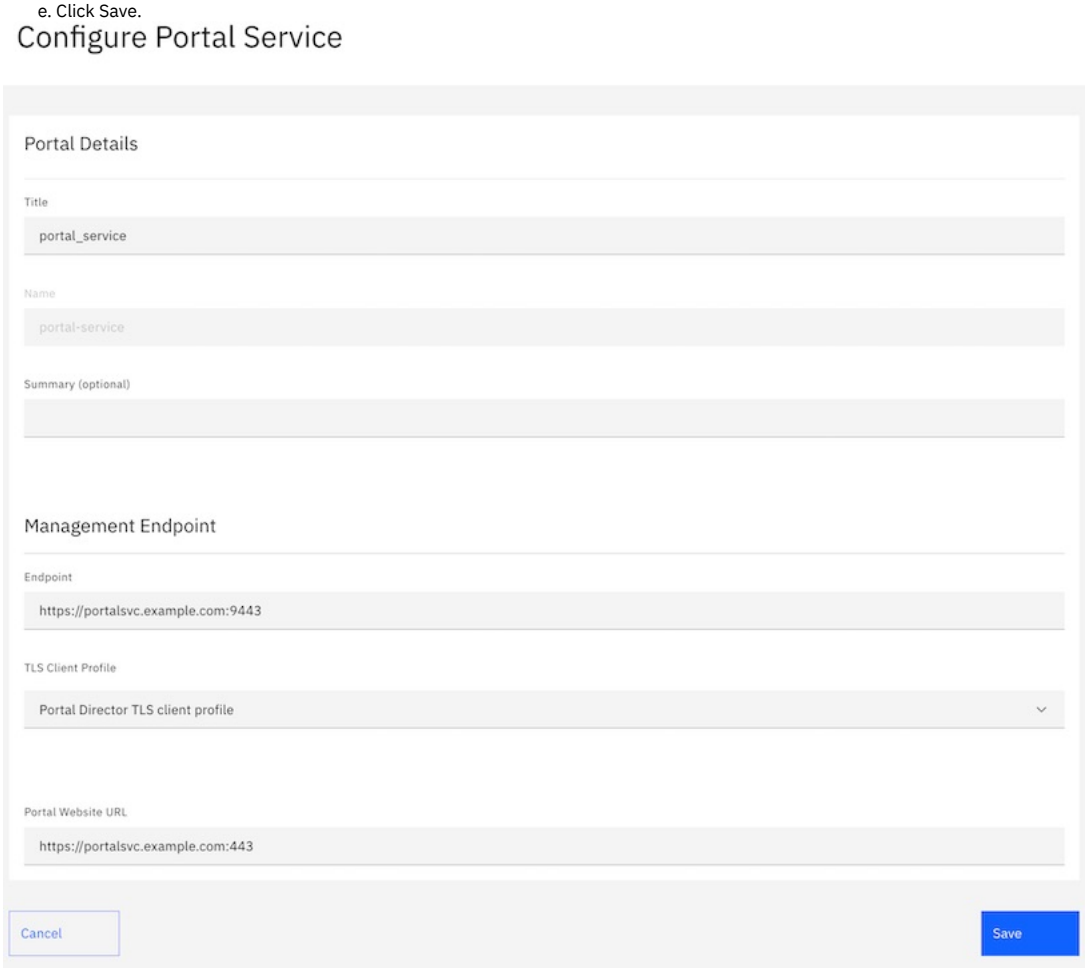
      ```
      kubectl config set-context --current --namespace=<namespace>
      ```

      iii. List the ingress resources and locate the API Connect ingress for your instance; unless overridden, the name ends in **`-ibm-egw-rt`**:

      ```
      kubectl get ingress
      ```

iv. Copy the URL for the ingress resource from the **`Host`** column and append the port **`:443`**.

d. Leave the remaining values as given to set TLS profiles.

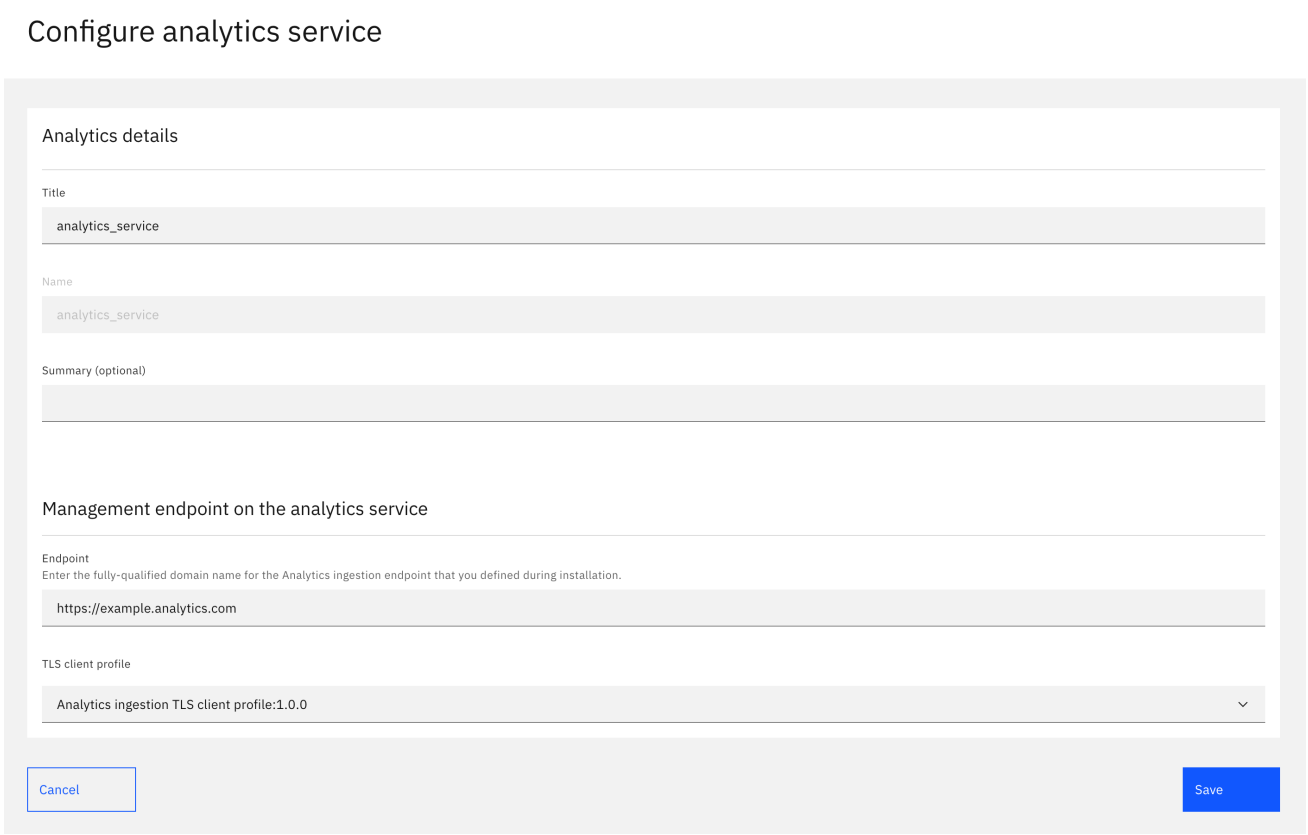


e. Do not change the defaults in the Server Name Indication (SNI) fields. unless your topology requires different values.

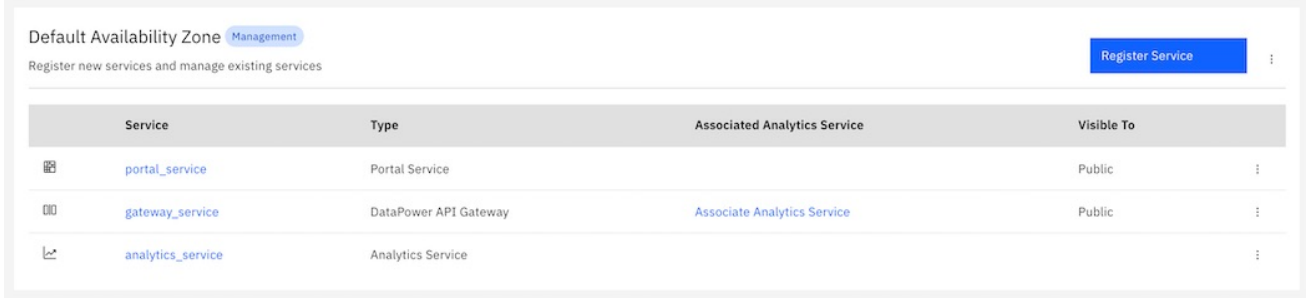
f. Click Save.

Register a Portal Service

Take the following steps to register a portal service.

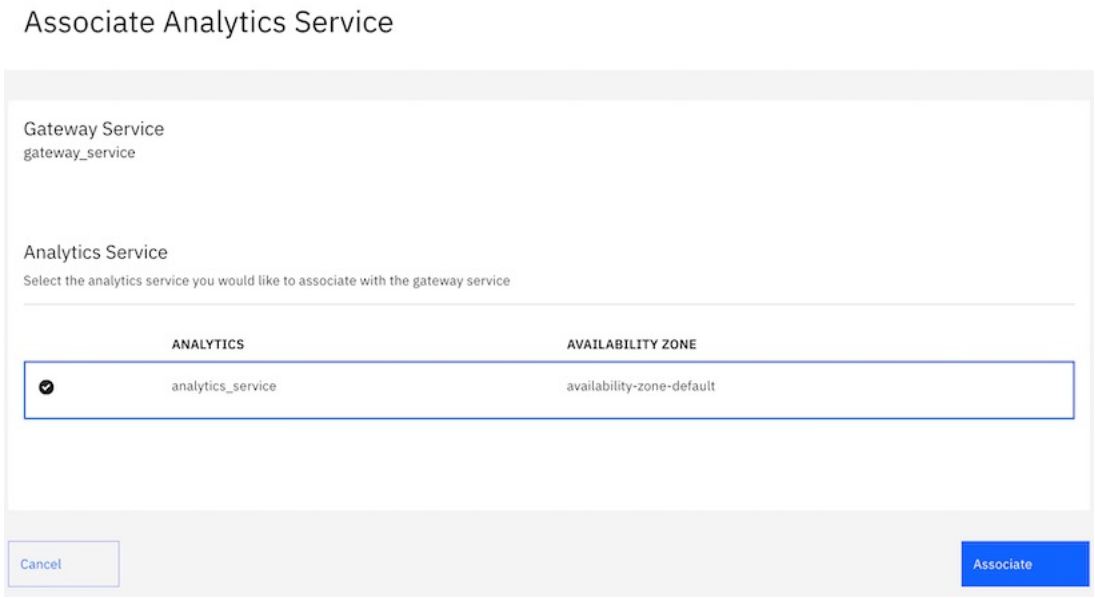


1. Click Register Service.
2. Click Portal.
3. Take the following steps.
   a. Enter `portal_service` in the Title field.
   b. In the Management Endpoint section, enter the URL of the portal address and port assigned to communicate with the management server in the Endpoint field.
   c. Enter the URL of the portal address and port assigned to accept requests from clients in the Portal Website URL field.
   d. Use the reconfigured profile in the TLS Client Profile field.
   e. Click Save.



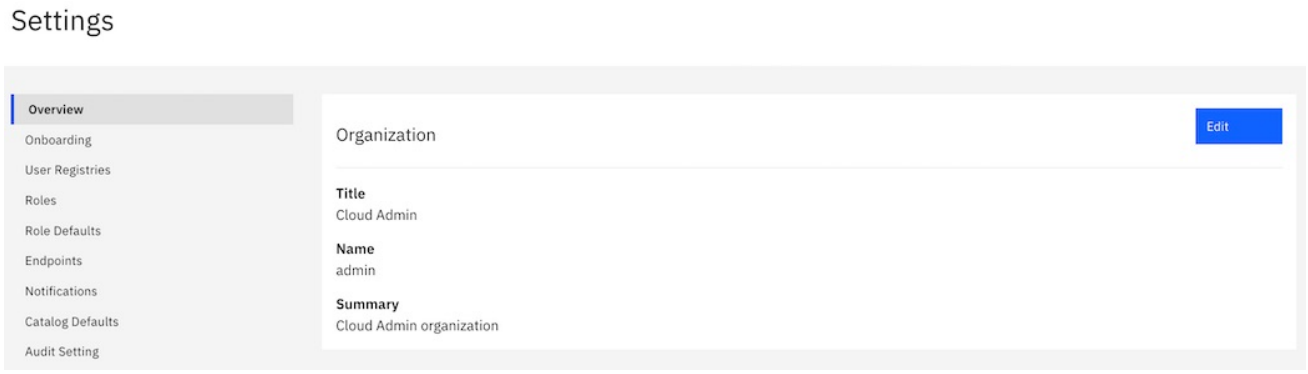
Register an Analytics Service

Take the following steps to register an analytics service.

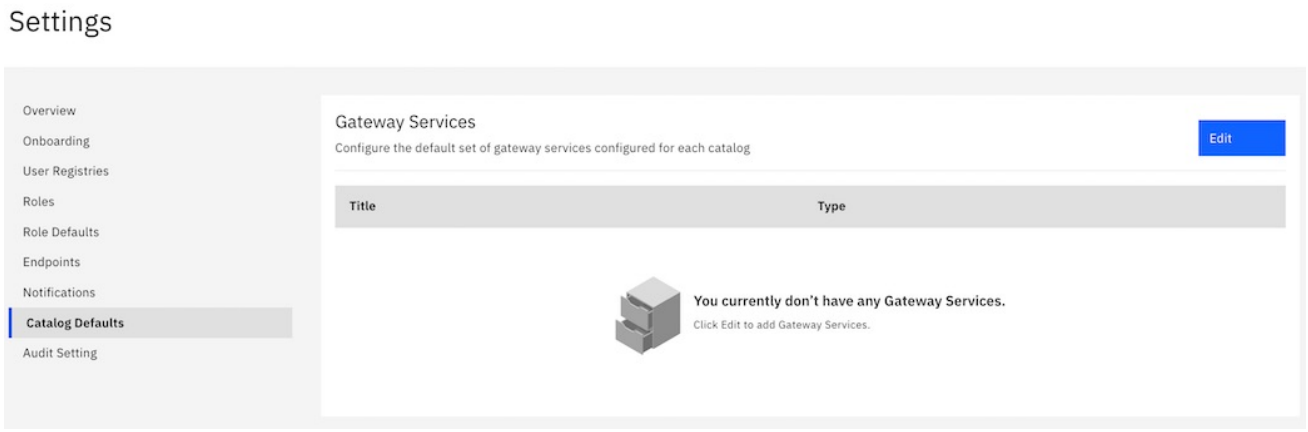


1. Click Register Service
2. Click Analytics.
3. Take the following steps.
   a. Enter `analytics_service` in the Title field.
   b. In the Management Endpoint section, enter the URL of the analytics server address and port assigned to accept requests from clients in the Endpoint field.
   c. Select `Analytics ingestion TLS client profile` in the TLS Client Profile field.
   d. Click Save.

4. Click Associate Analytics Service corresponding to the gateway service listing.

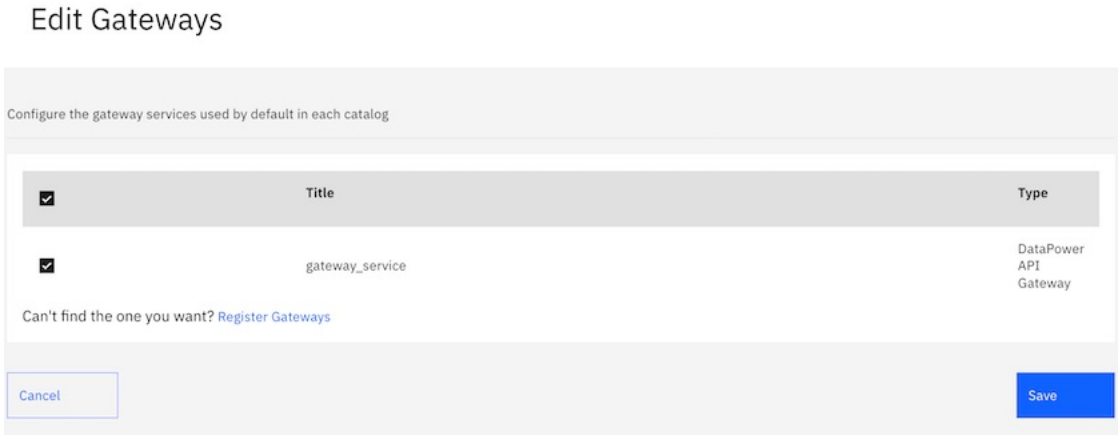


5. Select analytics_service. Click Associate.



Configure a Default DataPower Gateway Service

Take the following steps to configure a default DataPower gateway service for every catalog in the cloud.



1. Click Settings icon .
2. Click Catalog Defaults.

3. Click Edit.

4. Select an available gateway service.
5. Click Save.

What you did in this tutorial

- Set new Cloud Manager Console login password
- Configured a DataPower Gateway Service
- Configured an Event Gateway Service
- Configured a Developer Portal Service
- Configured an Analytics Service
- Configured a Notifications Email Server
- Configured a Catalog Default DataPower Gateway Service

Tutorial: Creating a Provider Organization

This tutorial shows you how to create a Provider Organization.

Before You Begin

This task can be completed by users who are assigned one of the following roles:

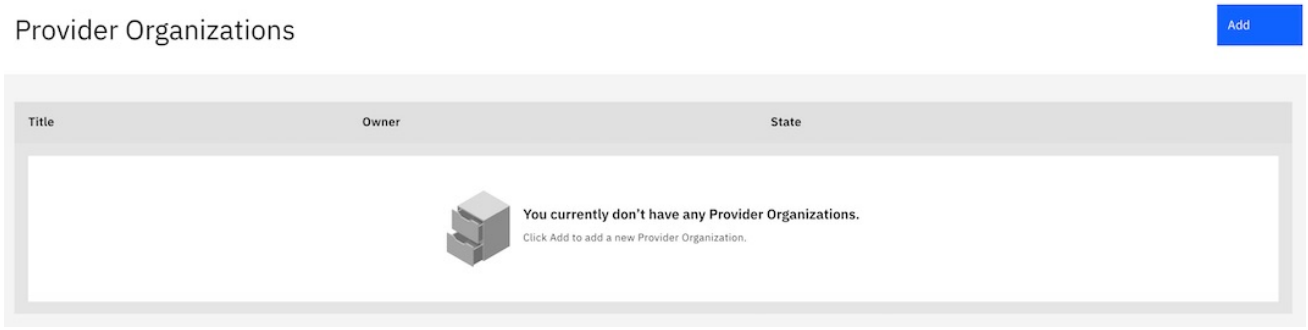
- Cloud Owner
- Cloud Administrator

You must also complete the following tasks before beginning:

- Configuring an email server for notifications
- Setting up notifications

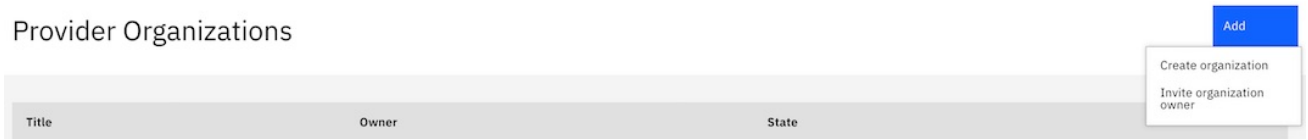
Note that an email server must be configured and an active email server must be selected before a provider organization account can be created.

About this tutorial



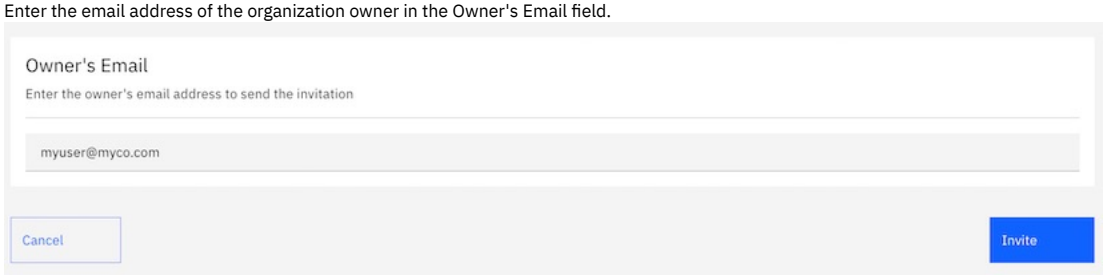
In this tutorial you are going to complete the following lessons:

- Create a Provider Organization

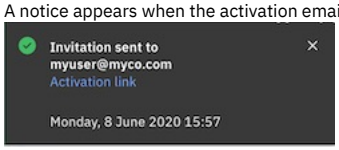


Create a Provider Organization

Take the following steps to create a new Provider Organization.

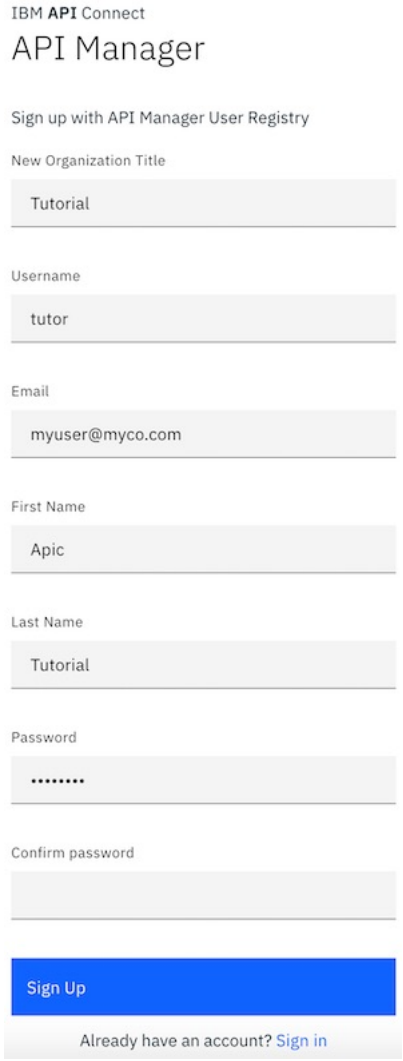


1. Log in to the Cloud Manager.
2. Click Provider Organizations.

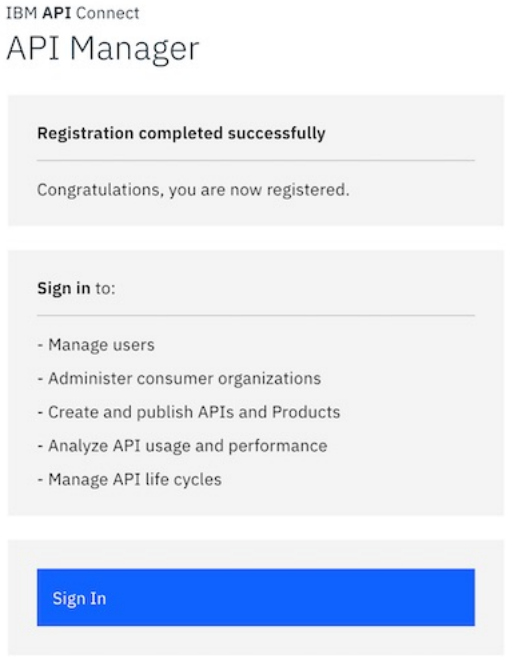


3. Click Add > Invite organization owner.

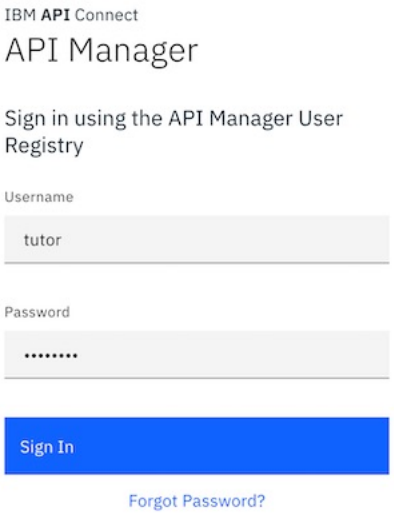
4. Enter the email address of the organization owner in the Owner's Email field.



5. Click Invite.
6. A notice appears when the activation email has been sent. Click Activation link..



7. A dialog box displays the activation link. Click the Copy to clipboard icon .



8. Open a new window in your browser. Paste the copied activation link into the Location bar. Optionally, you can click the activation link in the invitation email to open the registration form.
9. Complete fields shown in the form to sign up with the API Manager User Registry. Click Sign up.

10. You see a confirmation of registration. Click Sign in.

11. Enter the username and password you just created. Click Sign in to begin creating APIs and products.

12. Return to the original window of your browser. Click Provider Organizations to refresh the list. Your new organization is listed.

What you did in this tutorial

In this tutorial, you completed the following activities:

- Created a new Provider Organization.

- Importing an API

Developing your APIs and applications

You develop APIs by using the IBM® API Connect developer toolkit.

The API Connect developer toolkit provides both the API Designer user interface and a command line interface that you can use to develop APIs and publish them to API Connect.

Security tip: While developing your API, remember to protect sensitive data that might be exposed to consuming applications. For information on configuring security requirements for your APIs, see Enforcing security requirements on an API.
You publish APIs by including them in a "product" and then publishing that product. Define your APIs and products by creating and validating YAML definition files in your local file system, or using the API Connect UI. You can then interact with API Connect using either the UI or the toolkit commands.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
The developer toolkit is described in detail in the following subsections:

- **API development checklist**
  A summary, with links, of the key tasks for developing APIs in IBM API Connect.
- **API discovery**
  Use API discovery to discover the APIs in your organization, and copy them into API drafts to enable lifecycle management.
- **Working with the toolkit**
  Install the developer toolkit by downloading an executable file. You can then use the toolkit commands to interact with IBM API Connect and publish APIs that you have defined in your file system.
- **Managing platform REST API keys**
  Create API keys associated with your user account, and then use them to authenticate when you call the platform REST APIs provided by API Connect.
- **Searching for items in API Manager**
  Use the search feature in IBM API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.
- **Working with API definitions**
  An API definition specifies the complete configuration for an API. You can create and configure your APIs either by using either the API Designer UI application, or

by using the browser based API Manager UI.

- **Working with Products**
  In IBM API Connect, Plans and APIs are grouped together in Products, with which you can manage the availability and visibility of APIs and Plans.
- **Creating and validating API and Product definitions by using the CLI**
  The developer toolkit of IBM API Connect provides a command line interface that you can use to create and publish API and Product definitions, and also to validate YAML or JSON definitions.
- **Working with global policies**
  Use global policies to configure policy assemblies that are called just before, or just after, each of your API assemblies is called, or when an error is thrown. You can upload global policies into each of the gateway services in your Catalogs, and then designate, for each gateway service, which global policy should be called before an API assembly is called, after an API assembly is called, or if an error occurs when an API assembly is called. The designated global policies are applied to all the APIs that are deployed to the associated gateway service.
- **Reference**
  Reference information for developing your APIs in API Connect, including context variables, and template variables.

API development checklist

A summary, with links, of the key tasks for developing APIs in IBM® API Connect.

Task	Description
Activate your API Manager user account	For you to be able to connect to a Management server by using either the API Designer or API Manager user interfaces, one or other of the following prerequisites must be satisfied: • Your administrator has created a provider organization, specifying you as the owner; see Creating a provider organization. • You have been added as a member of a provider organization; see Adding provider organization users and assigning roles.
Install the developer toolkit	The developer toolkit provides a command-line environment and an API Designer user interface, both of which enable you to develop and work with your APIs on your local machine; you publish your APIs to the Management server when ready. You can also develop your APIs directly on the Management server by using the API Manager user interface.
Log in to the user interface; see Logging in from API Designer, or Accessing the API Manager user interface, depending on which user interface you want to use.	After you have activated your account, you can log in to your Management server from either user interface. You can also use the API Designer in offline mode, but to be able to test and publish APIs you must be connected to a Management server.
Create your API definitions	You can create API definitions in the following ways: • Create a REST API definition either by composing the API definition, and its operations, from scratch, creating a proxy API that calls an existing endpoint, or importing an OpenAPI definition. • Expose an existing SOAP service as an API. • Create a GraphQL API proxy definition that proxies a backend GraphQL server.
• Secure your APIs (OpenAPI 2.0) • Secure your APIs (OpenAPI 3.0)	You configure security for an API by creating one or more security definitions that you then apply to your API, and to the operations in your API. Security mechanisms include basic authentication through a user registry, and token based authentication with OAuth.
Test your APIs	The user interfaces provide a test tool with which you can test your APIs through the gateway.
Productize and publish your APIs	To make your APIs available to application developers, you include them in a Product that you then publish to the gateway.
Apply visibility controls and rate limiting to your APIs	Visibility settings control which APIs the application developers can subscribe to. Rate limiting controls the usage of your APIs; for example, you can apply a rate limit of 100 calls per minute.
Develop your APIs by using the developer toolkit CLI	You can use the developer toolkit CLI to develop APIs based on OpenAPI definition files in YAML or JSON format.

API discovery

Use API discovery to discover the APIs in your organization, and copy them into API drafts to enable lifecycle management.

IBM® API Connect includes an optional API discovery capability that enables you to quickly discover the APIs in your organization. You can then easily copy the APIs that you want to work with into API drafts, so that they can be fully managed within API Connect. API discovery uses data source collectors that are configured to integrate with gateways and ingresses to give you the visibility of the API traffic in your networks. The logs from this traffic are forwarded to the discovery capability, analyzed, and then API documents are generated and presented for review. These generated API documents can then be copied to draft APIs as required, to enable full lifecycle management.

Note:

- Before you can create API discovery sources, the API discovery capability must be enabled on your provider organization by your system administrator. For more information, see Enabling API discovery on Kubernetes and Enabling API discovery on VMware.

The following types of data source collectors are supported:

- GitHub
- DataPower® API Gateway proxy
- OpenTelemetry

Restriction: The following limitations apply to the API discovery capability.

- The API discovery capability is available only in the API Manager UI. It's not available in the API Designer UI.
- The toolkit CLI can be used for operations on the discovered APIs and sources, but not on configuring the collectors.

See the following topics for detailed information about how to configure and run API discovery.

1. Configure one or more data source collectors for discovering APIs:
   - Configuring a GitHub collector for API discovery
   - Configuring a DataPower API Gateway proxy collector for API discovery
   - Configuring an OpenTelemetry collector for API discovery
2. Discover and review the APIs that are collected. See Reviewing your discovered APIs.
3. Manage the lifecycle of your discovered APIs. See The API discovery lifecycle in API Manager.

- **Configuring a GitHub collector for API discovery**
  How to add a GitHub data source collector to your API discovery capability.
- **Configuring a DataPower API Gateway proxy collector for API discovery**
  How to add a DataPower API Gateway proxy data source collector to your API discovery capability.
- **Configuring an OpenTelemetry collector for API discovery**
  How to add an OpenTelemetry collector to your API discovery capability. The collector can be based on an Istio or an NGINX data source.
- **Reviewing your discovered APIs**
  How to review the discovered OpenAPI documents in your API discovery capability.
- **The API discovery lifecycle in API Manager**
  When you manage your discovered APIs in the API Manager UI, you move them through a series of lifecycle states. From initially discovering an OpenAPI document, through to copying that document to API drafts to make it available to your API developers, and to eventual archiving.

Configuring a GitHub collector for API discovery

How to add a GitHub data source collector to your API discovery capability.

Before you begin

Before you can configure an API discovery GitHub collector, the following prerequisites are required:

- You must have a GitHub repository that contains one or more OpenAPI reference documents.

One of the following provider organization roles is required to be able to manage sources:

- Organization Administrator
- Owner
- Custom role with the **`Settings: Manage`** permission.

About this task

API discovery is an optional add-on to IBM® API Connect that can be used to discover and add APIs to your API development process. Before you can discover any APIs, you must configure one or more data source collectors. These collectors then get automatically added to the Sources tab in the API Manager UI when the collector sends the first OpenAPI documents to your provider organization.

To configure an API discovery GitHub collector, you create a GitHub Actions workflow in your GitHub repository. This workflow enables your OpenAPI reference documents to be automatically sent to, and kept in sync with, API Connect. These OpenAPI documents can then be copied to draft APIs as required, to enable full lifecycle management in API Manager.

Note: When an API with a large payload is sent (for example, a complex API that's more than 1 MB in size), there might be some delay in creating the discovered API. It is recommended that you don't run another workflow simultaneously, until you see that an API has been created in the API discovery service.

Procedure

To configure a GitHub collector, complete the following steps.

1. Create a .github/workflows directory in your repository on GitHub (if that directory doesn't already exist).
2. In the .github/workflows directory, create a file for your workflow action, for example discover-api.yml.
3. In the workflow action file, copy the following workflow job.
   The following YAML contains the workflow for the **`run-discovery`** job. On a push commit to the GitHub repository, this job checks to see if there are any changes to the files or folders specified and, if there are, the job sends the git difference of the commits in the files to API Connect. **`API_FILES`** can be changed to **`API_FOLDERS`** when one or more entire folders need to be discovered.

```
name: Sync Discovered API with APIConnect

on: [pull_request, workflow_dispatch, push]

env:
  API_HOST: <host-name>
  PLATFORM_API_PREFIX: <platform-api>
  PROVIDER_ORG: <porg-name>
  API_FILES: <file/files name>

jobs:
  run-discovery:
    runs-on: ubuntu-latest
    steps:
    - uses: actions/checkout@v4
    - name: Difference
```

```
      id: difference-output
      run: |
        echo "action_updates=$(git diff --name-only --diff-filter=ACMRT ${{ github.event.before }} ${{ github.sha }} |
xargs)" >> $GITHUB_OUTPUT
    - uses: ibm-apiconnect/apic-discovery-action@main
      id: discover-apis
      with:
        api_host: ${{ env.API_HOST }}
        platform_api_prefix: ${{ env.PLATFORM_API_PREFIX }}
        provider_org: ${{ env.PROVIDER_ORG }}
        api_key: ${{ secrets.apicApikey }}
        if: env.API_FILES
        api_files: ${{ env.API_FILES }}
        else if: env.API_FOLDERS
        api_folders: ${{ env.API_FOLDERS }}
        resync_check: ${{ true }}
        git_diff: ${{ steps.difference-output.outputs.action_updates }}
    - name: Display the action-result
      run: |
        echo "Result of the action: ${{ steps.discover-apis.outputs.action-result }}"
        echo "End"
```

Note that you can optionally also use the following **check_changes_job** workflow file. On a push commit to the GitHub repository, this job checks to see if there are any changes to the files or folders specified, or a change to the discover-api.yml file, and if there are, the job sends the files to API Connect. **API_FILES** can be changed to **API_FOLDERS** when one or more entire folders need to be discovered.

```
name: Sync Discovered API with APIConnect

on: [pull_request, workflow_dispatch, push]

env:
  API_HOST: <host-name>
  PLATFORM_API_PREFIX: <platform-api>
  PROVIDER_ORG: <porg-name>
  API_FILES: <file/files name>

jobs:
  check_changes_job:
    runs-on: 'ubuntu-20.04'
    # Declare outputs for next jobs
    outputs:
      action_changed: ${{ steps.check_workflow_changed.outputs.action_updates }}
      changed_filename: ${{ steps.changed_filename.outputs.api_file }}
      apifiles_env: ${{ steps.changed_filename.outputs.apifiles_env }}
      folder_changed: ${{ steps.check_apifolders_changed.outputs.folder_updates }}
    steps:
    - uses: actions/checkout@v4
      with:
        fetch-depth: 2
    - name: Check Workflow changed
      id: check_workflow_changed
      run: |
        echo "action_updates=$(git diff --name-only --diff-filter=ACMRT ${{ github.event.before }} ${{ github.sha }} |
grep discover-api.yml | xargs)" >> $GITHUB_OUTPUT
    - name: Changed API File Name
      id: changed_filename
      run: |
        echo "api_file=$(git diff --name-only --diff-filter=ACMRT ${{ github.event.before }} ${{ github.sha }} | xargs)"
>> $GITHUB_OUTPUT
        echo "apifiles_env=$(echo $API_FILES)" >> $GITHUB_OUTPUT
    - name: Check API Folders changed
      id: check_apifolders_changed
      run: |
        echo "folder_updates=$(git diff --name-only --diff-filter=ACMRT ${{ github.event.before }} ${{ github.sha }} |
grep $API_FOLDERS | xargs)" >> $GITHUB_OUTPUT
  run-discovery:
    runs-on: ubuntu-latest
    needs: [ check_changes_job ]
    if: ${{ (contains(needs.check_changes_job.outputs.apifiles_env,needs.check_changes_job.outputs.changed_filename)) ||
(needs.check_changes_job.outputs.action_changed) || (needs.check_changes_job.outputs.folder_changed) }}
    steps:
    - uses: actions/checkout@v4
    - uses: ibm-apiconnect/apic-discovery-action@main
      id: discover-apis
      with:
        api_host: ${{ env.API_HOST }}
        platform_api_prefix: ${{ env.PLATFORM_API_PREFIX }}
        provider_org: ${{ env.PROVIDER_ORG }}
        api_key: ${{ secrets.apicApikey }}
        if: env.API_FILES
        api_files: ${{ env.API_FILES }}
        else if: env.API_FOLDERS
        api_folders: ${{ env.API_FOLDERS }}
        resync_check: ${{ needs.check_changes_job.outputs.action_changed && true || false }}
    - name: Display the action-result
      run: |
        echo "Result of the action: ${{ steps.discover-apis.outputs.action-result }}"
```

Where:

- **name** is the name of your GitHub Action workflow.
- **API_HOST** is the domain name of the API Connect instance where the discovered APIs will be sent. For example, **dw-rosa-01.owe.p1.openshiftapps.com**.
- **PLATFORM_API_PREFIX** has a default value of **platform-api**. You can change it to match your system configuration, if different.

- **INSECURE_SKIP_TLS_VERIFY** if set to **true**, this action skips the validity check for the server certificate. This action might be required if your API Connect system is using self-signed certificates. Note that setting this action to **true** makes your HTTPS connections insecure.
- **PROVIDER_ORG** is the name of the API Connect provider organization.
- **API_FILES** or **API_FOLDERS** specifies whether you want single or multiple API files or folders to be considered for the workflow action. Separate multiple files or folders by using a comma, for example **mail-api.yaml,my-api.json,APIfolder/pet-exp.json**. The API files can be in json or yaml format.
- **resync_check** indicates whether changes to the action, such as at initial creation, should trigger an api-file synchronization.
- **git_diff** checks the difference between the current and the previous commit. If multiple files have changed in the commit, the workflow only runs if one or more of the files supplied in **API_FILES** or **API_FOLDERS** has changed.
- **api_key** are the credentials that are required for pushing API files to the API Manager. You can get the API key from the user who has access to the API Manager for posting APIs. For information about how to obtain an API key, see Managing platform REST API keys. You must then store the API key in a GitHub secret, that can then be used by this GitHub Action workflow. In the YAML in this step the **api_key** is called **apicApikey**, so if you want to reuse this YAML ensure that you create your secret with the same name. For information about how to store API keys as secrets in GitHub Actions, see Using secrets in GitHub Actions in the GitHub Docs.

To understand more about the **apic-discovery-action**, and how to use it, see apic-discovery-action and apic-discovery-test on **github.com**. These API Connect resources include working examples with a test repository.

4. Commit the workflow file to a branch in your GitHub repository.
   Committing the workflow file triggers a **push** event and runs the sync workflow with API Connect.
5. In the API Manager UI, click the Discover icon  , then click the Sources tab to view your GitHub collector.
   Sources can have the following status:
   - Enabled - the source is enabled, and synchronizes with the collector according to its configuration.
   - Disabled - the source is disabled, and API Connect won't accept any files from the collector. This status is set by the discovery service if a discovery operation fails.
   - Unhealthy - the source collector is unavailable.
   - Paused - the source is paused, and API Connect won't accept any files from the collector.
6. Optional: You can click the Options icon ⋮ next to a source to change its status.
   - Pause collector - to pause the source.
   - Delete collector - to delete the source from the API Manager UI. The external source files are not deleted.
   - Resume collector - to restart a paused or disabled source.
7. Optional: You can click the Manage columns icon on the table header to change the order and view of the columns.

Results

Your GitHub data source collector is now ready to synchronize with API Connect. When the collector sends the first OpenAPI documents to your provider organization, the collector becomes listed in the Sources tab in the Discover section of API Manager. A GitHub collector posts updates to API Connect only when a difference is detected due to a commit or PR event in the original data source.

What to do next

You can click the APIs tab in the Discover section of the API Manager UI, and review the API traffic in your GitHub source. For more information, see Reviewing your discovered APIs.

Configuring a DataPower API Gateway proxy collector for API discovery

How to add a DataPower® API Gateway proxy data source collector to your API discovery capability.

Before you begin

Before an API discovery DataPower API Gateway proxy collector can collect data from a provider organization, you must first enable sharing of your provider organization analytics data; see Sharing analytics data for API discovery.

One of the following provider organization roles is required to be able to manage sources:

- Organization Administrator
- Owner
- Custom role with the **Settings: Manage** permission.

About this task

API discovery is an optional add-on to IBM® API Connect that can be used to discover and add APIs to your API development process. Before you can discover any APIs, you must configure one or more data source collectors. These collectors then get automatically added to the Sources tab in the API Manager UI when the collector sends the first OpenAPI documents to your provider organization.

To configure an API discovery DataPower API Gateway proxy collector, you can either create a proxy API definition, or update an existing proxy API, in your provider organization in API Connect. This new or existing proxy API will contain the endpoint of an existing REST service that you want to use to discover OpenAPI documents from. The discovered OpenAPI documents can then be copied to draft APIs as required, to enable full lifecycle management in API Manager. If you're updating an existing proxy API definition, the minimum fields that are required for collection to occur, are the inclusion of the **invoke** policy **log** segment, and both of the **set-variable** segments, that are shown in the example YAML in Step 1.

Procedure

To configure a DataPower API Gateway proxy collector by using the API Manager UI, complete the following steps. You can also use the toolkit CLI to create your proxy API definition. For general information about how to use the toolkit CLI, see Overview of the command-line tool.

1. Create a YAML file for your proxy API definition, like the following example:

```
swagger: '2.0'
info:
  version: version
  title: title
  x-ibm-name: name
  contact:
    name: contact_name
basePath: /
x-ibm-configuration:
  properties:
    target-url:
      value: target_url
      description: url_description
      encoded: false
  cors:
    enabled: true
  gateway: datapower-api-gateway
  type: rest
  phase: realized
  enforced: true
  testable: true
  assembly:
    execute:
      - invoke:
          title: invoke
          version: 2.0.0
          verb: keep
          target-url: $(target-url)$(request.path)$(request.search)
          follow-redirects: false
          timeout: 60
          parameter-control:
            type: allowlist
            values: []
          header-control:
            type: blocklist
            values: []
          inject-proxy-headers: true
          persistent-connection: true
      - log:
          version: 2.1.0
          title: log
          log-level: default
          mode: gather-only
      - set-variable:
          version: 2.0.0
          title: set-variable
          actions:
            - set: log.custom_data.discoveryServiceCollection
              value: 'true'
              type: string
          description: Setting specific collector key
      - set-variable:
          version: 2.0.0
          title: set-variable
          actions:
            - set: log.custom_data.apiTargetURL
              value: $(target-url)
              type: string
          description: Setting specific collector target URL
    catch: []
    finally: []
  activity-log:
    enabled: true
    success-content: payload
    error-content: payload
  catalogs: {}
  buffering: true
paths:
  /{+pathparam}:
    get:
      responses:
        '200':
          description: success
          schema:
            type: string
      consumes: []
      produces: []
    post:
      responses:
        '201':
          description: success
          schema:
            type: string
      consumes: []
      produces: []
    put:
      responses:
```

```
        '201':
          description: success
          schema:
            type: string
    patch:
      responses:
        '200':
          description: success
          schema:
            type: string
      consumes: []
      produces: []
    delete:
      responses:
        '204':
          description: success
          schema:
            type: string
      consumes: []
      produces: []
    parameters:
      - name: +pathparam
        in: path
        required: true
        type: string
schemes:
  - https
```

Where:

- ***version*** is the version number of the API.
- ***title*** is the title of the API. For example, **My proxy API**.
- ***name*** is the name of the API. The value of the ***name*** field must be a single string that can be used to identify the API in commands, for example, **my-proxy-api**.
- ***contact_name*** is the name of a contact for the API.
- ***target_url*** is the URL endpoint of the existing REST service that you want to expose. For example, **https://myorg.com/api/**.
- ***url_description*** is a description of the target URL.
- **$(target-url)$(request.path)$(request.search)** is an **invoke** policy that allows wildcard paths and parameters to be passed after the ***target_url*** endpoint of the existing REST service. Suffixing the **$(target-url)** with **$(request.path)$(request.search)**, means that any number (1-n) of request paths and any number (1-n) of path parameters that are invoked by the users of the API, are captured and processed by the discovery collector, regardless of them not being explicitly defined in the proxy OpenAPI schema definition.
- **log** is a **log** policy that enables a custom log to been added.
- **set-variable** are **set-variable** policies that set a specific collector key called **discoveryServiceCollection**, and a specific collector target URL called **apiTargetURL**. The collector uses the **discoveryServiceCollection** key to filter analytics data for events that are associated with the proxy API definition, and the **apiTargetURL** to filter the duplicate invokes from different data sources.
- **activity-log** is an **activity-log** policy that decides how complete the discovered OpenAPI reconstruction is. Setting both **success-content** and **error-content** fields to **payload** gives the collector enough data to be able to ensure that the request and response schemas can be created correctly. You can also set these fields to **activity** or **header** data, which in both cases means that less of the OpenAPI structure is discoverable. Note that the collector does not look at the payload values, and these values are redacted before being sent from the collector to the discovery capability.
- **paths** is set to a wild card value, for example **{+pathparam}**, to ensure that there is the maximum range of discoverable paths available on the proxy API. The **paths.parameters** section should be defined to the same value. Under the **paths:/{+pathparam}** property, stub methods for **get**, **post**, **patch**, **put**, and **delete** can be added to give maximum reach through the proxy for all of the operations that can be discovered.

2. Log in to your provider organization in the API Manager UI.
3. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
4. In the Import section, select Existing OpenAPI, then click Next.
5. Choose one of the following methods to select your YAML file:
   - Drag and drop the file.
   - Browse for the file.
   - Specify the URL of the file.

   The wizard checks the validity of the YAML, and displays a message indicating successful validation.
6. Click Next to import the selected file.
   A summary of the import confirms that an API definition is created.
7. Click Edit API.
   Your API definition opens in the Design tab.
8. Click the Test tab to start making your API discoveries.
   You use the Request field to find your API traffic by passing the **GET**, **POST**, **PATCH**, **PUT**, and **DELETE** methods through the proxy API. For example:

   ```
   GET https://myorg.com:9443/test/sandbox/users
   ```

   Returns a list of users.
   After API traffic is found, the DataPower API Gateway proxy collector becomes available in the API discovery capability.
9. In the API Manager UI, click the Discover icon  , then click the Sources tab to view your DataPower API Gateway proxy collector.
   Sources can have the following status:
   - Enabled - the source is enabled, and synchronizes with the collector according to its configuration.
   - Disabled - the source is disabled, and API Connect won't accept any files from the collector. This status is set by the discovery service if a discovery operation fails.
   - Unhealthy - the source collector is unavailable.
   - Paused - the source is paused, and API Connect won't accept any files from the collector.
10. Optional: You can click the Options icon ⋮ next to a source to change its status.
    - Pause collector - to pause the source.
    - Delete collector - to delete the source from the API Manager UI. The external source files are not deleted.
    - Resume collector - to restart a paused or disabled source.

11. Optional: You can click the Manage columns icon on the table header to change the order and view of the columns.

Results

Your DataPower API Gateway proxy data source collector is now ready for API traffic discovery. The collector posts updates to API Connect when a manual request for testing is made, or when the proxy API is provided to users, in order to interact with the applications that are accessible on the paths that are available behind the ***target_url*** of the proxy. Every time an API definition is discovered and processed, the Last run field of the data source is changed to reflect the activity.

What to do next

You can click the APIs tab in the Discover section of the API Manager UI, and review the API traffic in your data source collector. For more information, see Reviewing your discovered APIs.

Configuring an OpenTelemetry collector for API discovery

How to add an OpenTelemetry collector to your API discovery capability. The collector can be based on an Istio or an NGINX data source.

Before you begin

Before you can configure an API discovery OpenTelemetry collector, the following prerequisites are required:

- You need to download both the helm chart and collector image from https://github.com/ibm-apiconnect/api-discovery-otel-collector/.
- You must have the Helm package manager for Kubernetes installed on your client. For more information, see the Helm installation guide at https://helm.sh/docs/intro/install/.
- If your data source is Istio:
  - You must have Istio installed on your cluster where you want to discover the API traffic from. If you don't have Istio installed, see the Getting Started guide at https://istio.io/latest/docs/setup/getting-started/.
  - You need to deploy both the Istio mesh, and the sample application. For more information, see the Istio Getting Started guide at https://istio.io/latest/docs/setup/getting-started/.
- If your data source is NGINX:
  - You must have NGINX installed on your cluster where you want to discover the API traffic from. If you don't have NGINX installed, see the NGINX installation guide at https://docs.nginx.com/nginx/admin-guide/installing-nginx/.

One of the following provider organization roles is required to be able to manage sources:

- Organization Administrator
- Owner
- Custom role with the **`Settings: Manage`** permission.

About this task

API discovery is an optional add-on to IBM® API Connect that can be used to discover and add APIs to your API development process. Before you can discover any APIs, you must configure one or more data source collectors. These collectors then get automatically added to the Sources tab in the API Manager UI when the collector sends the first OpenAPI documents to your provider organization.

To configure an API discovery OpenTelemetry collector, you must configure your Istio or NGINX data source, and then deploy the collector by using a Helm chart. After the collector is deployed, any pods that have API traffic running through Envoy then send this data to API Connect. The OpenAPI documents can then be copied to draft APIs as required, to enable full lifecycle management in API Manager.

You can deploy the Istio Collector in the following modes depending on the configuration and functionality:

- Istio Telemetry - collects general data such as HTTP method, path, host, status code, content type, and other metadata.
- Istio EnvoyFilter - collects request and response bodies, as well as APIs from the installed applications.

Procedure

To configure an OpenTelemetry collector, complete the following steps.

1. Configure your Istio or NGINX data source to support the collector.

   Configuring an Istio data source
   Telemetry collector_mode
   Register the collector in your Istio **`MeshConfig`** by running the following command, and adding a discovery provider.

   ```
   kubectl edit configmap istio -n istio-system
   ```

   Where ***`istio-system`*** is the namespace where Istio is deployed on your cluster. The default namespace is **`istio-system`**.

Update the **extensionProviders** section with the following information:

```
    extensionProviders:
      - name: "discoveryOtelCollector"
        opentelemetry:
          service: "management-api-discovery-otel-collector.istio-system.svc.cluster.local"
          port: 5555
```

For more information about providers, see the Provider Selection section in the Istio documentation at https://istio.io/latest/docs/tasks/observability/telemetry/#provider-selection.
If you deployed Istio by using the **IstioOperator**, you can configure the information by using the **MeshConfig**. For more information, see the Istio documentation at https://istio.io/v1.10/docs/reference/config/istio.mesh.v1alpha1/#MeshConfig.

EnvoyFilter collector_mode

a. Deploy an existing REST API application or a new one and its associated services. Ensure that the Istio VirtualService is deployed and configured to manage traffic to the application.
Note:
As part of the Istio deployment, the application pods in the namespace should be annotated with the **sidecar.istio.io/inject: true** annotation. This will automatically inject the Istio Envoy sidecar proxy into each pod to enable the service mesh functionality.

b. Install the Open telemetry collector. This will automatically install the EnvoyFilter Istio Custom Resource (CR) from the provided YAML template (**EnvoyFilter.yaml**) in the **collector_mode** configuration specified in the **values.yaml** file. You can view all the envoy configurations applied to a pod using **istioctl**
proxy-config as well as filter the results to see the configured envoy clusters, listeners, routes, and more.
For example, run the **istioctl proxy-config** command against the created REST API pod to verify that the EnvoyFilter has been successfully applied to the pod.

```
istioctl pc listener <podname> -n <namespace> -o yaml
```

Configuring the istioctl proxy

a. Modify the logging level on the REST API pod so that the logs generated by the WASM filter are visible in the debug logs. This will allow for more detailed logging and debugging capabilities, enabling you to inspect the Envoy proxy's behavior and troubleshoot any issues related to the WASM filter. For example,

```
istioctl pc log <podname> -n <namespace> --level debug
```

b. Configure the Envoy Wasm filter to collect API calls made by the REST API app and them to the OTEL collector at a frequency of every 3 minutes. This will enable the Wasm filter to intercept and discover API calls made by the REST API, allowing for the collection of metrics and tracing data that will be sent to the OTEL collector for further analysis and monitoring.

c. Check the Wasm filter logs using the istio-proxy logs on the pod.

```
kubectl logs <podname> -n <namespace> -c istio-proxy
```

Uninstalling the EnvoyFilter

a. Run the following CLI command:

```
kubectl delete EnvoyFilter wasm-envoy-filter -n istio-system
```

b. Restart all the pods that are configured in any namespaces to collect traces through EnvoyFilter.

Configuring an NGINX data source

There are multiple ways that you can configure your NGINX data source to support the OpenTelemetry collector, but the following information shows the four main options. For more detailed information about the configuration, see the NGINX readme on **github.com**.

a. NGINX **otel-webserver-module**
To configure the **webserver** module to send traces to the OpenTelemetry collector, you can update the NGINX deployment to use the **OTEL_EXPORTER_OTLP_ENDPOINT**. For example:

```
env:
- name: OTEL_EXPORTER_OTLP_ENDPOINT
  value: management-api-discovery-otel-collector.namespace.svc:5555
```

Or, you can update the **NginxModuleOtelExporterEndpoint** in the OpenTelemetry configuration on your NGINX server.

b. NGINX **instrumentation** module
Similarly to the **webserver** module, you can update the NGINX deployment to use the **OTEL_EXPORTER_OTLP_ENDPOINT**, or you can configure the endpoint in the **otel-nginx.toml**.

This module allows different variables to be used in the **nginx.conf** in order to customize the traces that can be sent to the API discovery service.

c. Ingress-Nginx Controller
The Ingress-Nginx Controller uses the **instrumentation** module, so the same configuration options apply. As a minimum, the Kubernetes Ingress-Nginx Controller **ConfigMap** needs to be configured with the following details to collect the traces from the backend service:

```
enable-opentelemetry: "true"
otlp-collector-host: "management-api-discovery-otel-collector.namespace.svc:5555"
```

d. NGINX OpenTelemetry module
You can configure this module to send traces to the OpenTelemetry collector by setting the **otel_exporter** in the NGINX configuration.

This module allows different variables to be used in the **nginx.conf** in order to customize the traces that can be sent to the API discovery service.

2. In your Helm directory, update the values.yaml file with the following parameter values, as required for your collector configuration.
   - **discovery.datasource_type** - the field that configures the datasource type to decide if a specific telemetry or EnvoyFilter configuration is required. If the datasource type is **istio**, the required Istio Telemetry CR or Istio EnvoyFilter CR is installed. Otherwise, Helm ignores the telemetry creation.
   - **discovery.datasource_name** - the datasource name for all of the APIs that are discovered by the collector (optional). If the datasource name is empty, the namespace of the collected API is used.
   - **discovery.apic_host_domain** - the domain name of the API Connect instance where the discovered APIs are being sent. For example, **dw-rosa-01.owe.p1.openshiftapps.com**.

- **`discovery.provider_org`** - the name of the provider organization in API Manager.
- **`discovery.api_key`** - the credentials that are required for pushing API files to the API Manager. You can get the API key from the user who has access to the API Manager for posting APIs. For information about how to obtain an API key, see Managing platform REST API keys. The **`api_key`** is added to a Kubernetes secret as part of the deployment, and then mounted on the collector deployment pod.
- **`discovery.processors`** - the flag to enable or disable the processors. Can be set to **`enabled`** or **`disabled`**. If set to **`enabled`**, the **`ConfigMap`** enables the existing batch and memory limiter processor, and will not provide any processors in other cases. If you attempt to send a trace with more than 11000 spans at a time, the collector will reject the payload, and you will be required to turn on the batch processor. The available batch and memory limiter processors are configurable according to the base system requirements. The **`limit_mib`** in the memory limiter processor can be increased if you update the resource limits of the collector deployment. Keeping the **`attributes/ibm-apiconnect`**, **`redaction/ibm-apiconnect`**, **`filter/ibm-apiconnect`**, **`transform/ibm-apiconnect`**, and **`resource/ibm-apiconnect`** processors in the **`service.pipelines.traces.processors`** in the same order when enabling processors is required, as there are built-in processors that enhance the performance of the collector. If you don't include these processors, the quality of the collected traffic is degraded, as well as the performance of the collector. For more information, see an example processor ConfigMap template, information about the OpenTelemetry batch processor, and information about the OpenTelemetry memory limiter processor.
- **`namespace`** - the namespace where Istio or NGINX is deployed on your cluster. As required by the Istio telemetry integration, the collector pod will also be deployed here.
- **`images.api_discovery_collector`** - enables the upgrade of the collector deployment as new versions are released. Note that collectors will require updates in the future to ensure that they remain compatible with the discovery service. Details of any updates are available in the https://github.com/ibm-apiconnect/api-discovery-otel-collector repository.
- **`logging.log_level`** - the log level; the default level is **`info`**. For debug purposes the level can be increased to **`debug`** if needed.
- **`logging.debugexporter_verbosity`** - the verbosity level of the debug log; the default value is **`basic`**. For detailed information about the exporter, the verbosity level can be increased to **`detailed`**. However, it is recommended to keep the verbosity as **`basic`** for a collector with a large amount of traffic flowing through it.

The following values are specific to Istio data sources:

- **`Collector mode`** - You can install Istio either as Istio telemetry or Istio EnvoyFilter. By default, the **`collector mode`** is set as **`telemetry`** in the values.yaml file and the telemetry CR is installed. Set the **`collector mode`** to **`EnvoyFilter`**in the values.yaml file to install EnvoyFilter in the **`istio-system`** namespace.
- **`telemetry_namespace`** - the namespace where the Istio Telemetry CR will be deployed (optional). By default, the values file sets this namespace to **`istio-system`**, as the root configuration namespace to provide mesh level collection configuration. However, this setting can be customized based on your collection requirements for the deployed applications that you want to be discovered. For more information, see the Telemetry information at https://istio.io/latest/docs/reference/config/telemetry/.

The following example shows some sample parameter values for an Istio data source:

```
---
discovery:
  # platform_api_prefix is not required to change for API Connect on Cloud
  datasource_type: istio
  # supported values are istio, nginx
  datasource_name: my-data-source
  platform_api_prefix: platform-api
  apic_host_domain: us-east-a.apiconnect.automation.ibm.com
  provider_org: myOrgName
  api_key: xxxxxx
  namespace: istio-system
  # supported values are telemetry, envoyfilter
  collector_mode: telemetry
  telemetry_namespace: istio-system
  # Enable the processor and edit the processor-configmap to choose values for batch and memory_limiter
  # supported values are enabled and disabled
  processors: disabled
logging:
  log_level: info
  # supported values are json and console
  log_encoder: json
  # supported values are basic and detailed
  debugexporter_verbosity: basic

images:
  api_discovery_collector: ghcr.io/ibm-apiconnect/api-discovery-otel-collector:20240612-173911
```

To understand more about configuring the OpenTelemetry collector, see the OpenTelemetry collector for API discovery readme on **`github.com`**. These API Connect resources include working examples with a test repository.

3. Run the following command to deploy the collector:

   ```
   helm template . | kubectl apply -f -
   ```

   The following example shows the response displayed for an Istio data source, confirming that the required Kubernetes resources are deployed:

   ```
   helm template . | kubectl apply -f -
   secret/api-discovery-secret created
   service/management-api-discovery-otel-collector created
   deployment.apps/management-api-discovery-otel-collector created
   telemetry.telemetry.istio.io/api-discovery-otel created
   ```

   After the collector is deployed, any data source instrument pods that have traffic running through Envoy will start to be discovered, and the traffic sent to the API Connect discovery capability.
4. The view the collector, and any traffic being received, log in to your provider organization in the API Manager UI.
5. In the navigation pane, click the Discover icon  , then click the Sources tab to view your OpenTelemetry collector.
   Sources can have the following status:
   - Enabled - the source is enabled, and synchronizes with the collector according to its configuration.
   - Disabled - the source is disabled, and API Connect won't accept any files from the collector. This status is set by the discovery service if a discovery operation fails.
   - Unhealthy - the source collector is unavailable.
   - Paused - the source is paused, and API Connect won't accept any files from the collector.
6. Optional: You can click the Options icon ⋮ next to a source to change its status.

- Pause collector - to pause the source.
- Delete collector - to delete the source from the API Manager UI. The external source files are not deleted.
- Resume collector - to restart a paused or disabled source.

7. Optional: You can click the Manage columns icon on the table header to change the order and view of the columns.

Results

Your OpenTelemetry data source collector is now ready to discover API traffic. When the collector sends the first OpenAPI documents to your provider organization, the collector becomes listed in the Sources tab in the Discover section of API Manager.

What to do next

You can click the APIs tab in the Discover section of the API Manager UI, and review the API traffic. For more information, see Reviewing your discovered APIs.

If required, you can uninstall the collector from Helm by running the following command:

```
helm template . | kubectl delete -f -
```

Reviewing your discovered APIs

How to review the discovered OpenAPI documents in your API discovery capability.

Before you begin

One of the following roles is required to be able to edit discovered APIs:

- Organization Administrator
- Owner
- Custom role with any of the following permissions:
  - Settings: Manage
  - Api-Drafts: Edit

A custom role with the Settings: View or Api-Drafts: View permission is able to view discovered APIs.

About this task

API discovery is an optional add-on to IBM® API Connect that can be used to discover and add APIs to your API development process. After a source collector is added to the API discovery capability, you can manage the discovered OpenAPI documents in API Manager.

Procedure

To manage your discovered OpenAPI documents, complete the following steps.

1. In the API Manager UI, click the Discover icon , and then ensure that the APIs tab is selected.
2. The list of discovered OpenAPI documents is displayed in the table. The OpenAPI documents in the list are updated according to the configuration settings on their source.
   The OpenAPI documents can have one of the following states:
   - Discovered - the OpenAPI document is discovered by the source.
   - Copied to drafts - the OpenAPI document is copied to the APIs tab in the Develop section of the API Manager UI.
3. To view the metadata of an OpenAPI document, click the Options icon next to the document that you want to review, and select View metadata.
   A brief description of the API is displayed. You can then click View API to view the complete OpenAPI document, or click Hide API to hide the API in the list.
4. To view the complete OpenAPI document, click the title of the document in the APIs table.
   A read-only version of the complete OpenAPI document is displayed, which you can explore in the UI. You can also download the OpenAPI document as a JSON or YAML file.
5. To copy an OpenAPI document into a draft API, you can use one of the following methods:
   - From the list of available OpenAPI documents in the APIs tab, click the Options icon next to the document that you want to copy, and select Copy to draft.
   - From within an OpenAPI document, click Copy to draft.

   You can then click the APIs tab in the Develop section of the API Manager UI, and your copied document is shown in the list of APIs. You can now edit and manage the lifecycle of this API in API Manager; for more information, see API development checklist and Working with API definitions.
6. Optional: You can click the Options icon next to an OpenAPI document to further manage the document. The following options are available:
   - Download - to download the API.
   - View metadata - to view a brief description of the API.

- Copy to draft - to copy the document into a draft API.
- Hide API - to hide the document from the list of APIs. Hidden APIs can be unhidden by clicking the Filters icon , selecting Hidden APIs under the Show category, and clicking Apply. You can then select the Show API option against the document that you want to display again. To see the API, you must then change the filter to clear the Hidden APIs checkbox.
- Remove API - to remove the document from the list of APIs. If the API has been copied to drafts, the API is removed only from the list of discovered APIs; it isn't removed from list of draft APIs. A removed API can be discovered again if it still exists in the source. If you want to remove an API document from the list, and not discover it again, you can select the Hide API option.

7. Optional: You can click the Manage columns icon on the table header to change the order and view of the columns.

Results

You reviewed your discovered OpenAPI documents, and copied the required APIs to drafts to enable full API lifecycle management in API Manager.

The API discovery lifecycle in API Manager

When you manage your discovered APIs in the API Manager UI, you move them through a series of lifecycle states. From initially discovering an OpenAPI document, through to copying that document to API drafts to make it available to your API developers, and to eventual archiving.

The following sections describe the various lifecycle states for a discovered OpenAPI document.

Discovered

The OpenAPI document is discovered by the source. The document can be reviewed, and can be Copied to drafts to enable full API lifecycle management. The document can also be downloaded, hidden from view, or removed from the list of APIs.

Copied to drafts

The OpenAPI document is copied to the APIs tab in the Develop section of the API Manager UI. The API is visible to your provider organization, and can be edited and managed through the full API lifecycle. For more information, see the API development checklist and Working with API definitions.

Hidden APIs

The OpenAPI document is hidden from the list of APIs. Hidden APIs can be unhidden by clicking the Filters icon , selecting Hidden APIs under the Show category, and clicking Apply. You can then select the Show API option against the document that you want to display again. To see the API, you must then change the filter to clear the Hidden APIs checkbox.

Removed APIs

The OpenAPI document is removed from the list of APIs. If the API has been copied to drafts, the API is removed only from the list of discovered APIs; it isn't removed from the list of draft APIs. A removed API can be discovered again if it still exists in the source. If you want to remove an API document from the list, and not discover it again, you can use the Hide API option.

Working with the toolkit

Install the developer toolkit by downloading an executable file. You can then use the toolkit commands to interact with IBM® API Connect and publish APIs that you have defined in your file system.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
The following subsections describe how to install and use the toolkit:

- **Installing the toolkit**
  You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM API Connect.
- **Logging in from API Designer**
  To log in from the API Designer user interface for IBM API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.
- **Using the developer toolkit command-line tool**
  The IBM API Connect developer toolkit provides a command-line tool, `apic`, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

Installing the toolkit

You can install the toolkit that provides CLI commands, and the API Designer user interface, for IBM® API Connect.

About this task

The toolkit is provided as executable files, so no actual installation is necessary, you just to need to download the required compressed file and extract the contents.

There are two toolkit options available:

- CLI: provides a command line environment for working with IBM API Connect.
- CLI + Designer: provides a command line environment for working with IBM API Connect, including API Designer application.

To install the toolkit, download the compressed file that is appropriate for your chosen toolkit option and platform, then extract the contents to a chosen location on your local machine. The compressed file contains an executable file for running CLI commands and, if you choose the CLI + Designer option, an executable file for launching the API Designer application.

You can download the toolkit from one of the following locations:

- From IBM Fix Central.
- From the Cloud Manager or API Manager user interface.

Procedure

To install and run the toolkit, complete the following steps:

1. Download the toolkit compressed file.
   - To download the toolkit from IBM Fix Central, complete the following steps:
     - Open the IBM Fix Central site in your browser.
     - In the Product selector field, enter `API Connect`, then select IBM API Connect from the drop down list.
     - Select your Installed Version and click Continue. If you do not know your installed IBM API Connect version, contact your administrator.
     - In the Text field, enter `toolkit`, then click Continue.
     - Select the toolkit file that you want to download.
     - Click Continue, then follow the instructions to complete the download operation.
   - To download the toolkit from Cloud Manager or API Manager user interface, complete the following steps:
     - Open the Cloud Manager or API Manager user interface.
     - On the welcome page, click the Download Clients tile. The two toolkit options are listed under the Toolkit tab.
     - Click your platform alongside either the CLI option or the CLI + Designer option as required, then save the associated compressed file to your local file system.
     - To download the API Designer credentials (Client ID and Client Secret), click Download alongside API Designer Credentials, then save the designer_credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 5.
     - To download the toolkit credentials (Client ID and Client Secret), click Download alongside Credential, then save the credentials.json file to your local file system. A command is provided for installing the credentials, as described in detail in step 4.
2. Extract the contents of the toolkit compressed file to a folder of your choice.
   The contents of the file depend on the your chosen toolkit option and platform, as follows:
   - The apic-slim or apic-slim.exe file is the CLI for IBM API Connect.
   - The apic or apic.exe file is the CLI for IBM API Connect.
     Tip: If you are using the CLI option, then if you rename the apic-slim file to apic, or the apic-slim.exe file to apic.exe, you can run the CLI commands exactly as documented, copy and paste sample commands from the documentation, and use any command scripts as-is if you later move to the CLI + Designer option.
   - The api_designer-*platform* file is the API Designer user interface application for the specified platform.
3. Run the CLI.
   - For the macOS or Linux® platforms, complete the following steps:
     - Open a terminal instance and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Make the CLI file an executable file by entering the following command:

       ```
       chmod +x download_name
       ```

       Where *download_name* is the name of the toolkit file that you downloaded, either apic or apic-slim.
     - If you are using macOS, remove the quarantine attribute by running the following command:

       ```
       sudo xattr -dr com.apple.quarantine apic-slim
       ```

     - Run CLI commands as follows:

       ```
       ./apic command_name_and_parameters
       ```

       or

       ```
       ./apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see the toolkit CLI reference documentation.
   - For the Windows platform, complete the following steps:
     - Open a command prompt and navigate to the folder where you extracted the contents of the toolkit compressed file.
     - Run CLI commands as follows:

       ```
       apic command_name_and_parameters
       ```

       or

       ```
       apic-slim command_name_and_parameters
       ```

       For details of the CLI commands, see the toolkit CLI reference documentation.

   Tip: Add the folder location of your CLI file to your PATH variable so that you can run CLI commands from anywhere in your file system.
4. Install the toolkit credentials.
   If you do not install the toolkit credentials that are provided for download, as detailed previously in the toolkit credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect

system and are unique to your installation. To install the credentials into your local toolkit, run the following command:

```
apic client-creds:set toolkit_credentials_file_path/credentials.json
```

where *credentials_file_path* is the location to which you downloaded the toolkit credentials JSON file. After you have run this command, your toolkit uses these new credentials to authenticate with the management server.
Note: At any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
To revert to the default toolkit credentials for all login operations from the toolkit CLI, use the following command:

```
apic client-creds:clear
```

For increased security, an administrator can remove the default credentials from the management server by completing the following steps:

a. Log in to the management server as an administrator; see Logging in to a management server.
b. Delete the default credentials by running the following commands:

```
apic registrations:delete toolkit --server mgmt_endpoint_url
apic registrations:delete consumer-toolkit --server mgmt_endpoint_url
```

5. Install the API Designer credentials.
If you do not install the API Designer credentials that are provided for download, as detailed previously in the API Designer credentials download instructions, API Connect uses a default set of credentials that are identical for all deployments. However, the downloaded credentials were generated during the deployment of your API Connect system and are unique to your installation. To install the custom credentials into your local API Designer, set the **APIC_DESIGNER_CREDENTIALS** environment variable to the credentials download location, using the mechanism appropriate for your operating system.

   After you have set the **APIC_DESIGNER_CREDENTIALS** environment variable, your API Designer uses the new credentials to authenticate with the management server.

   - Windows:
     If you are using Windows, create an environment variable using one of the following methods:

     - Create a permanent environment variable so that you can start API Designer from any location on your computer:
       - Open the Environment Variables page: Click Start > Settings > System and in the "Related Settings" section of the page, click Advanced System Settings.
       - On the Advanced tab of the System Properties dialog box, click Environment Variables.
       - In the "User variables" section, click New and create an environment variables with the following settings:
         - Variable: **APIC_DESIGNER_CREDENTIALS**
         - Value: *<designer_credentials_file_path>*\designer_credentials.json where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.
       - Click OK to save the new environment variable, and then exit the dialog box.
     - If you don't have the required permissions to create a permanent environment variable, you can create a temporary one that will only be used while you are running the API Designer application. The following steps must be performed every time you start API Designer:
       - Open the Windows command prompt.
       - Run the following command to set the temporary environment variable:

         ```
         set APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>\designer_credentials.json
         ```

         where ***<designer_credentials_file_path>*** is the location where you stored the designer_credentials.json file.

         Note: Leave the command prompt open for the next step. You must set the temporary variable and start the API Designer within the same Windows command session.
       - Now run the following command to start API Designer:

         ```
         C:\"Program Files\API Designer\API Designer.exe"
         ```

         By default, API Designer is installed in the C:\"Program Files\API Designer folder as shown in the example. If you installed it into a different location, use your own location in the command. Note that the path and file name are enclosed in quotation marks because they contain spaces.

   - Mac:
     If you are using macOS, create an environment variable using one of the following methods:

     - Run the following command to set the global environment variable:

       ```
       launchctl setenv APIC_DESIGNER_CREDENTIALS <designer_credentials_file_path>/designer_credentials.json
       ```

       where ***<designer_credentials_file_path>*** is the location where you stored the API Designer credentials JSON file.
     - Pass in the environment variable while starting API Designer from the command line. With this method, you must run the following command every time you start API Designer:

       ```
       APIC_DESIGNER_CREDENTIALS=<designer_credentials_file_path>/designer_credentials.json open
       <designer_application_file_path>/'API Designer.app'
       ```

       where:
       - ***<designer_credentials_file_path>*** is the location to which you downloaded the API Designer credentials JSON file.
       - ***<designer_application_file_path>*** is the location to which you downloaded and uncompressed the API Designer application.
6. Start the API Designer application from the location to where you stored the extracted file.
   Note:
   - To uninstall the API Designer application on a Windows platform with a non Administrator account, complete the following steps:
     - In Windows File Explorer, navigate to the USER_HOME\AppData\Local\Programs\api-designer folder.
     - Run the **Uninstall API Designer application** application. Do **not** use the **Add or remove programs** window.
   - To uninstall the API Designer application on a Windows platform with an Administrator account, you can either run the **Uninstall API Designer application** application, or you can use the **Add or remove programs** window.

Results

The IBM API Connect toolkit CLI and, if selected, the API Designer user interface application are installed on your local system.

For information on using the API Designer user interface, see Developing your APIs and applications.

For information on using the toolkit CLI, see Using the developer toolkit command-line tool.

Logging in from API Designer

To log in from the API Designer user interface for IBM® API Connect, you will need the host name of the management server and the user name and password associated with your API Manager account.

About this task

API Designer provides a secure login to a management server for staging and publishing APIs and Products. You log in to the same host that was configured for API Manager and use your API Manager user name and password. You will need an account on API Manager and membership in a provider organization to access the API Designer.

You can also use the Explorer tab to see how your APIs look to a consumer in the Developer Portal. You can check the descriptions of the different artifacts, and refine any schemas or examples, and you can also use the Try it tool to test the behavior of the API.

Note:

- Configuration changes that are made in API Manager are not available in API Designer concurrently. You will need to log out of API Designer and log back in to access any updates.
- Set `SKIP_IBMID_LOGIN=true` as an environment variable to bypass the IBM ID login screen for API Designer. This applies to users who are working on an internal network, without access to external networks.

Procedure

To log in to API Designer, complete the following steps:

1. Download and extract API Designer, as described in Installing the toolkit.
2. Start the API Designer user interface by running the application from the location where you extracted the contents of the toolkit compressed file.
   Note: If you see a message stating that credentials cannot be found, download new credentials as explained in Downloading the toolkit.
3. Optional: If you see the Accept License page, click the URL read the license agreement, then click the button to accept the license. This prompt appears only one time. It does not appear once you have accepted the license on the current system.
4. Optional: If you see the IBM ID login page, enter your IBM customer ID.
   Note: You won't receive the IBM ID page if you are already authorized, or if you have set the `SKIP_IBMID_LOGIN` environment variable to `true`.
5. Open a directory on your local file system to store the API and Product specifications that you create in API Designer. The system defaults to a previously-accessed directory.
   If you want to switch to a different directory after logging in, click Switch directory on the menu bar in the header.

   Note: If you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, don't copy the file into your API Designer directory.
   Such an API will **not** be visible in the API Designer user interface if it doesn't contain the API Connect specific sections that are required by API Designer.

   Instead, copy the OpenAPI definition file to another folder, then import it into API Designer; the import operation adds the necessary API Connect specific sections; see Adding a REST API by importing an OpenAPI definition file.

   For more information on the API Connect specific sections in an OpenAPI definition file, see IBM extensions to the OpenAPI specification.

6. If this is the first time you have logged in, establish a connection to API Connect by completing the following steps:
   - Contact your administrator and request the "management endpoint URL" for connecting to API Connect.
     The management endpoint URL looks similar to the following example: https://*<host.domain>* and indicates the location where the API Manager is running.

     Note: If you are using API Connect as a component of Cloud Pak for Integration, the management endpoint URL follows this format:
     https://*cpd-your-company.domain*/integration/apis/*APIC_namespace*/*APIC_instance*

     Example: https://cpd-company.com/integration/apis/apic/production

     Do not add /manager to the URL. If you include /manager at the end of this URL, the connection with Cloud Pak for Integration will fail with a message stating that the host URL is invalid.

   - In the dialog window, enter the management endpoint URL as the Host URL and click Next.
   - Type the user name and password for your API Manager account.
   - Select a User Registry from the list.
   - Click Sign In.
7. For subsequent log ins, select the appropriate cloud where you will be working. You can select from any previous cloud connections.
8. When more than one cloud connection is configured, you can switch clouds when developing APIs and Products. See Switching clouds from API Designer.
   Note: If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.
9. Click Add Another Cloud to add another cloud connection. Enter the URL, user name and password, and user registry to add the cloud connection.
   Note: If you are using an OIDC user registry that supports single sign-on (SSO), and you are already logged in, you cannot add a new cloud connection to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then add the new cloud connection.
10. Delete a cloud connection by selecting the trash can icon.
11. API Designer will launch with the organization set to your provider organization in the selected cloud. If you have accounts for multiple provider organizations, it will default to the first organization in alphabetical order.
12. To choose another provider organization, select it from the drop-down list.

Setting the locale for API Designer

How to set one of the supported locales when you start the API Designer application.

About this task

If you want to use a different locale than your current operating system (OS) locale, you can set a locale code by using the **`--lang`** argument when you start the API Designer application. This locale is then effective for the duration that the application is open. If no **`--lang`** argument is set, then the current OS locale is used.

Procedure

To change the locale for API Designer, complete the following instructions.

From the command line, run the following command to start the API Designer application with the **`--lang`** argument:

Mac OS X Mac:

```
open "API Designer.app" --args --lang=locale_code
```

Windows Windows:

```
"API Designer".exe --args --lang=locale_code
```

Where ***`locale_code`*** is one of the following supported locale codes:

Table 1. List of supported locale codes and their associated language

Locale code	Language
`cs`	Czech
`de`	German (Standard)
`en-US`	English (United States)
`es`	Spanish
`fr`	French (Standard)
`it`	Italian (Standard)
`ja`	Japanese
`ko`	Korean
`nl`	Dutch (Standard)
`pl`	Polish
`pt-br`	Portuguese (Brazil)
`ru`	Russian
`tr`	Turkish
`zh-cn`	Chinese (PRC)
`zh-tw`	Chinese (Taiwan)

For example, running the following command on a Mac:

```
open "API Designer.app" --args --lang=es
```

sets the API Designer language to Spanish.

Switching clouds from API Designer

You can switch clouds to work in another cloud in API Designer.

About this task

API Designer allows the flexibility to connect to multiple clouds. For example, your organization may have separate clouds for testing, development, and demos. You select the cloud connection when you log in, but you can also switch clouds when you are developing APIs and Products. Multiple clouds must be configured in order to switch clouds. You must have a valid API Manager account to connect to a cloud.

Note: If you are using an OIDC user registry that supports single sign-on (SSO), you cannot switch clouds to log in to the same user registry with a different user ID. You must first restart the API Designer application so that you are logged out of the registry, then select the required cloud connection.

Procedure

To switch clouds for working in API Designer, complete the following steps:

1. Log in to API Designer and select a cloud, or configure a new cloud connection.
2. From the Develop: APIs and Products screen, you can switch to another cloud by selecting it from the Switch Cloud Connection menu.
3. Delete a cloud connection by selecting the trash can icon.

Working offline with API Designer

You can work offline (without a connection to the cloud) with API Designer to create APIs. Some functionality is missing due to the lack of a cloud connection.

About this task

API Designer provides the capability to work in offline mode without a connection to a management server. You can work on APIs with no management server, but some functions will be changed or missing.

The preferred method for working in API Designer is with a Cloud Connection to the management server when logging into API Designer. Working while connected to a management server provides full functionality, with automatic field completion. When working offline, you will need to remember the values to complete the fields that are backfilled from the management server.

Following are the differences when working in offline mode:

- There is no connection to a management server.
- There is no Provider Organization selection.
- Only the Develop APIs and Products tile may be selected. The Learn more and Connect menu tiles are not available.
- When creating an API, the Gateway Type defaults to V5 Gateway and the default policies are loaded.
- Stage and Publish for APIs and Products functions are not available.
- The Sandbox catalog is not available.
- When configuring a Security Definition, there are no selection lists available for the User Registry for a Basic Auth security definition or for the OAuth Provider for an OAuth 2 security definition. You will need to enter the User Registry and OAuth Provider values correctly as text.
- When adding custom Visibility and custom Subscribability values for a product, there is no selection list for the Organization field. You will need to enter the organization name correctly as text.

Procedure

To work in offline mode in API Designer, complete the following steps:

1. Log in to API Designer and open a directory location.
2. To start offline mode, choose Work Offline from the selector in the upper right corner of the Connect to Cloud screen.
3. The Home page appears with the Develop APIs and Products tile. Select Develop APIs and Products to start working in offline mode.
4. To return to online mode, choose Connect to Cloud in the upper right hand corner and select the management server to log in to.

Gathering support information in API Designer

When you report an issue with the API Designer application, enable debug mode and provide as much information as possible.

To report an issue with API Designer, enable debug mode, collect the recommended information, and submit it with your report. Including the information will help IBM resolve the problem more quickly.

- Enabling debug mode on Mac
- Enabling debug mode on Windows
- Enabling debug mode on Linux
- Information to gather for support

Enabling debug mode on Mac

Start API Designer with debug mode enabled:

1. Start a terminal or command prompt.
2. Navigate to the directory where API Designer is installed.
3. Run the following command to start API Designer in debug mode:

   ```
   DESIGNER_DEBUG=true open API/Designer.app/
   ```

   If you add **DESIGNER_DEBUG=true** to your .bash_profile, then every time you start API Designer it will open in debug mode.

Enabling debug mode on Windows

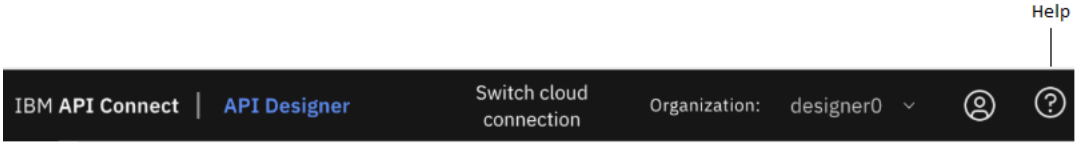
Add a Windows environment variable that enables debug mode for API Designer:

1. Type "Environment" in the Windows search bar (on the task bar) and select Edit environment variables for your account.
2. In the Environment Variables dialog box, click New in the "User variables" section.
3. In the New User Variable dialog box, add the following variable settings and then click OK:
   - Variable name: `DESIGNER_DEBUG`

   - Variable value: `True`

4. Click OK to save your change.

Enabling debug mode on Linux



To start API Designer with debug mode enabled, add the following command to your .bash_profile:

```
EXPORT DESIGNER_DEBUG=true
```

Information to gather for support

Gather the following information about your problem and include it with your report.

- Operating system where you are running API Designer (Mac, Windows, or Linux)
- Product versions for API Designer and the API Manager that is connects to:
  1. Open API Designer.
  2. Click the Help icon  on the navigation bar.

  3. On the Help page, click the Product information tile.
  4. On the Product information page, note down the following values for the following labels on the page:
     - Connected to API Manager Product version
     - Package
- HAR file
  The HAR file contains the information about your browser's interaction with the web, and can be helpful in determining why your problem is happening. Complete the following steps to export the HAR file from the browser where you use API Designer:

  1. Open API Designer.
  2. Open the browser's developer console; for example in Google Chrome, click > More tools > Developer tools.
  3. In the developer console, click the Network tab.
  4. Click  to download the HAR file.
- Are you using API Designer in Online mode or Offline mode?
  If you're using Online mode, are you connecting to a local test environment, or to an API Manager server?
- When does the problem happen?
  Provide reproducible steps with optional screen captures or video so the support team can recreate the problem.
- Supporting data.
  Provide any related data that would be useful while examining the problem; for example, a copy of the API or Product that you were using.
- How often does the problem happen?
  Is the problem intermittent? Does it happen constantly? Does it only happen with certain artifacts (for example, only with a particular API)? If the problem is associated with an artifact, try to include it with your report.

Using the developer toolkit command-line tool

The IBM® API Connect developer toolkit provides a command-line tool, **apic**, that you can use to perform all API Connect tasks. You can also use the command-line tool to script tasks such as continuous integration and delivery.

The command line tool is described in detail in the following subtopics. For summary reference material for each of the available commands for the developer toolkit, see the toolkit CLI reference documentation.

- **Overview of the command-line tool**
  The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- **Logging in to a management server**
  You log in to a management server from the command line by using the `apic login` command. The parameters that you supply determine the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.
- **Logging in to a management server with an OIDC registry**
  Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.
- **Cloud administration commands**
  A summary of the cloud administration commands in the IBM API Connect developer toolkit.
- **API development and management commands**
  A summary of the core commands in the IBM API Connect developer toolkit.
- **Creating APIs and applications**
  You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.
- **Publishing APIs and applications**
  To publish APIs and applications by using the developer toolkit of IBM API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.
- **Managing API Products**
  Use the `apic products` and `apic apis` commands to manage Products and APIs that have been published to IBM API Connect Catalogs. Use the `--scope space` option to manage Products and APIs that have been published to Spaces within Catalogs.
- **Working with Drafts**
  Co-locate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration, and so on. The developer toolkit provides the bridge from the developer's environment to the IBM API Connect runtime services.
- **Reading input from the command line**
  If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.
- **Scripting with the toolkit commands**
  The IBM API Connect developer toolkit provides commands for cloud administration and API development and management.
- **Working with OpenAPI extensions**
  Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.
- **Using the toolkit CLI to execute API tests**
  The IBM API Connect developer toolkit provides CLI commands for automated API behavior testing.

Overview of the command-line tool

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

Command syntax

In general, commands have the following syntax:

`apic command:sub-command [argument] [options]`

where

- *command* is the command, usually the thing on which you are acting (for example, product, app, API, Catalogs, and so on).
- *sub-command* is the action to perform.
- *argument* is the argument, where applicable (for example,`catalog`).
- *options* are any number of command-line options, which have the form `--option [value]`. Options also have a short form with a single dash instead of a double dash.

For example, `apic apps:publish --server mgmnthost.com`.
For some commands, either the command or sub-command portion is optional. For example:

- `apic products:publish` is equivalent to `apic publish`.
- `apic products:list` is equivalent to `apic products`.

The `create` command has a slightly different syntax:

`apic create:type [options]`

Use the `-h` or `--help` option to view command help.
Note: The language in which the CLI help text, and other command response text, is displayed is determined by the locale setting on your local machine.

Viewing command line tool help

Display general command-line help information by entering the following command: `apic --help` or `apic -h`. Display help information for a specific `apic` command by entering the following command: `apic command_name --help` or `apic command_name -h`.

Viewing version information

Display the version of the command-line tool by entering the command: `apic --version`.

Setting the mode

The API Connect toolkit CLI runs commands on either the provider organization or on the consumer organization. When you run the command, you use the different mode options to identify the instance on which you want to run the command. The following list provides a summary of the modes that are available:

apim
: This mode applies to the administrative instances of the CLI. When you run commands in this mode, it uses the overall API Manager as its scope. This mode is the default mode.
An example of running a command in the apim mode:

```
apic extensions:list-all --mode apim --scope catalog --server server1 --catalog catalog1 --org myOrg --configured-gateway-service service1
```

portaladmin
: This mode applies to the developer portal instances of the CLI. This mode supports commands that you can use to replicate all or part of your Developer Portal environment.
An example of running a command in the portaladmin mode:

```
apic --mode portaladmin custom-theme:create-export --catalog catalog1 --org myOrg --server server1 --format json
```

consumer
: This mode applies to the consumer instances of the CLI. This command uses the consumer organizations that you have permission to access as its scope. You must specify this mode or set it as the default value for the command to use it.
An example of running a command in the consumer mode:

```
apic catalogs:list --mode consumer --scope catalog --server server1 --catalog catalog1 --org myOrg
```

To avoid having to supply the parameter on every consumer CLI command, you can set the `mode` configuration variable, as described in the next section.

Using configuration variables

You can set the values of commonly-used properties in configuration variables. In general, it's easier and more consistent to set configuration variables instead of specifying them using command-line options.
Note:
The configuration variables for OpenAPI projects are always global. The values of global configuration variables are stored in the *user-home-dir*/.apiconnect/config file, where *user-home-dir* is the user's home directory.

Use the following commands to work with configuration variables:

- `apic config:get varname` - Get a configuration variable. Use `apic config` to display the values of all local configuration variables or `apic config -g` to display the values of all global configuration variables.
- `apic config:set varname` - Set or update the specified configuration variable.
- `apic config:delete varname` - Delete the specified configuration variable.
- `apic config:clear` - Delete all configuration variables.

You set configuration property values by using the **apic config:set** command. By setting configuration properties (for example `catalog` and `app`), you do not need to supply values for these options when you enter a command.

Additionally, you can use `apic properties` commands to work with configuration properties:

- `apic properties:clear` - Clear the configuration properties.
- `apic properties:create` - Augment the configuration properties with additional name/value pairs.
- `apic properties:delete` - Delete the configuration property.
- `apic properties:get` - Get the configuration property.
- `apic properties:list` - List the configuration properties.
- `apic properties:update` - Update the configuration property.

Note:
If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called `SPACE` then, by default, that value will be assumed for the value of the `--space` parameter in the following command, regardless of any `space` configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called `APIC_LOAD_FROM_ENV`, set to the value `false`.

The following table describes the configuration variables:

Table 1. Configuration variables

Variable name	Description	Use instead of (or override with) these flags...
catalog	Default Catalog name for all commands that manage aspects of a Catalog. The Catalog value can be specified as either: • The full Catalog URI that includes server name and organization name: `mgmt-server/api/catalogs/org-name/catalog-name`. In this case, you do not need to specify `--catalog`, `--organization`, or `--server` when you make CLI calls, since their values are included in the full Catalog URI. • The Catalog name, for example: `sandbox`. In this case, you still need to specify `--organization` and `--server` when you make CLI calls. Note: The Catalog name `apic-dev` is reserved for local testing.	• If Catalog URI used in variable assignment: `--catalog, --organization, --server` • If Catalog name used in variable assignment: `--catalog`
cloud	Default management server host name for cloud administration commands. Form: `mgmt-server/api/`.	`--server`

Variable name	Description	Use instead of (or override with) these flags...
consumer	Default URI of an API consumer. Form: ***`mgmt-server`*`/api/consumer-orgs/`*`org-name`*`/catalog-name/consumer-org-name`**, where *mgmt-server* is the management server, *org-name* is the organization name, *catalog-name* is the Catalog name, and *consumer-org-name* is the consumer organization name.	`--server, --organization, --catalog, --consumer`
mode	The default value of the `--mode` parameter for CLI commands. Set the value to `apim` or `consumer` depending on whether you want to run commands on a provider organization or a consumer organization. If you do not set this variable, and do not supply a `--mode` parameter on a command, the value `apim` is assumed.	--mode
org	Default org name for all commands that manage organizations. Form: ***`mgmt-server`*`/api/orgs/`*`org-name`**, where *mgmt-server* is the management server, *org-name* is the organization name. The org value can be specified as either: • The full org URI that includes the server name: ***`mgmt-server`*`/api/orgs/`*`org-name`**. In this case, you do not need to specify `--server` or `--organization` when you make CLI calls, since their values are included in the full org URI. • The org name, for example: `providerorg1`. In this case, you still need to specify `--server` when you make CLI calls.	• If org URI used in variable assignment: `--organization, --server` • If org name used in variable assignment: `--organization`
space	Default Space URI for all commands that manage aspects of a Space. Form: ***`mgmt-server`*`/api/spaces/`*`org-name`*`/catalog-name/`*`space-name`**, where *mgmt-server* is the management server, *org-name* is the organization name, *catalog-name* is the Catalog name, and *space-name* is the Space name. You can append the port number to the server name if it is not the default value of 443.	`--server, --organization, --catalog, --space`

To set configuration properties, enter the following command:

```
apic config:set name=value
```

where *name* is the name of the configuration property and *value* the value to assign to it.
For example:

```
apic config:set catalog=sandbox
```

Scripting commands

It's often helpful to automate a series of `apic` commands In a shell script. Since the `apic` tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.
To disable collection of usage analytics, enter this command:

```
apic --live-help
```

Setting the language

You can configure the language for the CLI command outputs by using the `--lang` flag. This flag allows the developer toolkit to provide command outputs in the specified language. The following table contains the supported languages:

Table 2. Supported languages

Language value	Language
en-us	English (US)
cs	Czech
de	German
es	Spanish
fr	French
it	Italian
ja	Japanese
ko	Korean
nl	Dutch
pl	Polish
pt-br	Portuguese (Brazil)
ru	Russian
tr	Turkish
zh-cn	Chinese (Simplified)
zh-tw	Chinese (Traditional)

Use a language values based on your needs. Use French as an example. To set the language to French, run the following command:

```
apic --lang fr
```

After you run the command, the outputs are displayed in French. For example:

```
apic config get invalid
Error: invalid n'est pas une variable de configuration valide
```

When you provide an invalid value that is not a supported language, the system displays the following error:

```
apic --lang invalid
Error: Value invalid is not valid for lang. Valid values are: en-us, cs, de, es, fr, it, ja, ko, nl, pl, pt-br, ru, tr, zh-cn,
zh-tw
```

Related information

Logging in to a management server

You log in to a management server from the command line by using the **apic login** command. The parameters that you supply determine the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.

Attention: If you want to log in with an OIDC user registry or if you are an IBM Cloud Pak for Integration (CP4I) user, see Logging in to a management server with an OIDC registry.

1. Clear the credentials from any previous login by running the following command:

   ```
   apic client-creds:clear
   ```

   Clearing the credentials ensures that you do not inadvertently log in with the wrong set of credentials (for example, from a different product release or environment).

2. Set the credentials that you want to use now by running the following command:

   ```
   apic client-creds:set path_to_credentials/credential.json
   ```

   Where *path_to_credentials* is the location of the credential.json file that you want to use. For example:

   ```
   apic client-creds:set /Users/local_user/credential.json
   ```

3. Log in using one of the following methods.
   - To log in using a username and password, run the following command:

   ```
   apic login --server mgmt_endpoint_url --username user_id --password password --realm realm
   ```

   - To log in using the apikey, run the following command:

   ```
   apic login --sso --server mgmt_endpoint_url --apiKey apikey --context provider
   ```

The parameters for the **apic login** command are as follows:

mgmt_endpoint_url
: The URL depends on the type of organization that you are logging in with:

  - Cloud admin organization or Provider organization, use one of the following URLs:
    - Platform API endpoint URL (note that if you want to run commands that relate to API governance, you must use the platform API endpoint URL to log in).
    - Management API manager URL.
  - Consumer organizations, use the consumer API endpoint URL.

  These endpoint URLs are configured during the installation of API Connect. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in Viewing platform and UI endpoints, ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

user_id
: The user ID you want to log in with. Depending on the tasks that you want to perform, this user ID might be any of the following:

  - A user ID that is a member of the cloud administration organization. This is an ID that you could also use to log in to the Cloud Manager user interface.
  - A user ID that is a member of a provider organization. This is an ID that you could also use to log in to the API Manager user interface.
  - A user ID that is a member of a consumer organization. This is an ID that you could also use to log in to the Developer Portal.

password
: The password associated with the supplied user ID.

realm
: The *realm* parameter specifies the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in.
  The format of the *realm* depends on the type of user, as follows:

  - Member of the cloud administration organization:

    ```
    admin/identity_provider
    ```

    To determine the identity provider, see How to determine the identity provider.

  - Member of a provider organization:

    ```
    provider/identity_provider
    ```

    To determine the identity provider, see How to determine the identity provider.

  - Member of a consumer organization:

    ```
    consumer:provider_org:catalog/identity_provider
    ```

where *provider_org* is the name of your provider organization, and *catalog* is the name of the Catalog in that provider organization.
To determine the identity provider, see How to determine the identity provider.

Important:

- If you have installed toolkit credentials, as detailed in Installing the toolkit, then at any one time, you can use only one set of toolkit credentials for login to a management server from the toolkit CLI. If you want to log in to a different management server you must install the toolkit credentials from that management server.
  To revert to the default pre-supplied toolkit credentials for all login operations from the toolkit CLI, use the following command:

  ```
  apic client-creds:clear
  ```

- If you log in to the CLI as a member of a consumer organization, you must supply the `--mode=consumer` parameter to the `apic login` command, and to all consumer commands. To avoid having to type the parameter every time, you can set the `mode` configuration variable, by entering the following command:

  ```
  apic config:set mode=consumer
  ```

apikey
: The apikey serves as the code to authenticate the user. For more information about creating apikey, see Managing platform REST API keys

You can also use the command interactively; enter `apic login` and you will be prompted for the values. For example:

```
apic login
Enter your API Connect credentials
Server? platform-api.myserver.com
Realm? provider/default-idp-2
Username? myuser
Password?
Logged into myserver.com successfully
```

Note: If you see a message stating that credentials cannot be found, download new credentials as explained in Downloading the toolkit.

How to determine the identity provider

If you want to log in as a member of the cloud administration organization, or as a member of a provider organization, you can help determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

```
apic identity-providers:list --scope scope --server mgmt_endpoint_url --fields title,realm
```

where *scope* has the value `admin` or `provider` depending on whether you want to log in as a member of the cloud administration organization, or as a member of a provider organization. The output lists the names and titles of all identity providers, for example:

```
apic identity-providers:list --scope admin --server myserver.com --fields title,realm
total_results: 2
results:
  - title: Cloud Manager User Registry
    realm: admin/default-idp-1
  - title: Corporate LDAP user registry
    realm: admin/corporate-ldap
```

The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time.
The default Cloud Manager Local User Registry for login as a member of the cloud administration organization is `default-idp-1`, and the default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
By default, API Connect creates a local user registry for user login for every context. The identity providers associated with these default registries are as follows:

Registry	Identity provider name
Cloud Manager Local User Registry (for login as a member of the cloud administration organization)	default-idp-1
API Manager Local User Registry (for login as a member of a provider organization)	default-idp-2
Sandbox Catalog User Registry (for login as a member of a consumer organization)	sandbox-idp

If you want to log in as a member of a consumer organization, see Logging in as a consumer to the Developer Portal by using the CLI for full details.

Logging out

To log out of a management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

Logging in to a management server with an OIDC registry

Logging in with an OIDC registry involves several steps, in which you obtain a temporary token and pass it to the toolkit to ensure it can communicate securely with the management server.

Attention: Logging in with an OIDC registry is supported for the developer toolkit (used with API Manager) and the Developer Portal admin toolkit, but is not supported for members of consumer organizations. If you are using IBM Cloud Pak for Integration (CP4I), review this topic for login instructions. If you want to log in using a non-OIDC registry, see Logging in to a management server.
To log in, complete the following steps:

1. Clear the credentials from any previous login by running the following command:

   ```
   apic client-creds:clear
   ```

Clearing the credentials ensures that you do not inadvertently log in with the wrong set of credentials (for example, from a different product release or environment).

2. Set the credentials that you want to use now by running the following command:

   ```
   apic client-creds:set path_to_credentials/credential.json
   ```

   where ***path_to_credentials*** is the location of the credential.json file that you want to use. For example:

   ```
   apic client-creds:set /Users/local_user/credential.json
   ```

3. Log in by running the following command:

   ```
   apic login --server mgmt_endpoint_url --sso
   ```

   where***mgmt_endpoint_url*** is the endpoint URL. When you log in with a Cloud admin or Provider organization, specify one of the following URLs:
   - platform API endpoint URL
   - management API manager URL

   These endpoint URLs are configured during the installation of API Connect. If you have access to the Cloud Manager user interface, you can view the configured endpoint URLs as described in Viewing platform and UI endpoints, ignoring any segments at the end of the displayed URLs. If you are not sure of the endpoint URL, ask your administrator.

   CP4I: If you are using API Connect as a component of IBM Cloud Pak for Integration (CP4I), your administrator can provide the correct URL.
4. When the toolkit prompts for the context, type **admin** API Connect (administrators) or **provider** (everyone else):

   ```
   Context? provider
   ```

5. The server responds with the following message:

   ```
   Please copy and paste the url https://mgmt_endpoint_url/auth/manager/sign-in/?from=TOOLKIT to a browser to start the authentication process.
   Do you want to open the url in default browser? [y/n]: y
   ```

   Take one of the following actions:

   - If you want to use your default browser to log in to API Manager, type **y** and press Enter.
     The API Manager sign-in page opens in a new browser tab.

   - If you don't use to use your default browser, type **n** and press Enter.
     - Copy the URL from the command window.
     - Open a browser, paste the URL, and press Enter.

     The API Manager sign-in page displays.

6. On the API Manager sign-in page, select the OIDC registry and then log in to API Connect.
   CP4I: Select the Common Services User Registry.
   After you log in, API Connect displays the "You are authenticated!" message and provides a temporary token. Copy the token.

7. Return to the command window. Paste the token at the **API Key?** prompt and press Enter.

When the token is validated and you are successfully logged in to the toolkit, the following message displays:

```
Warning: Using default toolkit credentials.
Logged into mgmt_endpoint_url successfully
```

Note: If you see a message stating that credentials cannot be found, download new credentials as explained in Downloading the toolkit.

Logging out

To log out of a management server, use the following command:

```
apic logout --server mgmt_endpoint_url
```

Cloud administration commands

A summary of the cloud administration commands in the IBM® API Connect developer toolkit.

Authenticating

Use the **apic login** command to authenticate to an API Manager service, and the **apic logout** command to remove your local authentication credentials.
Note: When you authenticate successfully, your credentials are stored, in plain text, in the file Linux .netrc or Windows _netrc. You should therefore set the file permissions in such a way that your credentials are not accessible by others.
For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Command summary

The following tables summarize **apic** commands for cloud administration.

Table 1. Summary commands for cloud administrators

Command	Description	Sub-commands

Command	Description	Sub-commands
apic analytics-services	Analytics Service commands	• **apic analytics-services** - Analytics Service collection operations. • **apic analytics-services:clear** - Clear the Analytics Services. • **apic analytics-services:create** - Create a Analytics Service. • **apic analytics-services:delete** - Delete the Analytics Service by name or ID. • **apic analytics-services:get** - Get the Analytics Service by name or ID. • **apic analytics-services:list** - List the Analytics Services. • **apic analytics-services:update** - Update the Analytics Service by name or ID.
apic associates	Associates commands	• **apic associates** - Associate collection operations. • **apic associates:get** - Get the Associate by name or ID. • **apic associates:list** - List the Associates.
apic availability-zones	Availability Zone commands	• **apic availability-zones** - Availability Zone collection operations. • **apic availability-zones:clear** - Clear the Availability Zones. • **apic availability-zones:create** - Create a Availability Zone. • **apic availability-zones:delete** - Delete the Availability Zone by name or ID. • **apic availability-zones:get** - Get the Availability Zone by name or ID. • **apic availability-zones:list** - List the Availability Zones. • **apic availability-zones:update** - Update the Availability Zone by name or ID.
apic cloud-settings	Cloud settings commands	• **apic cloud-settings:get** - Get the Cloud Setting. • **apic cloud-settings:mail-server-configured** - indicates whether a mail server has been configured. • **apic cloud-settings:topology** - Returns summary details of the configuration of your cloud topology. • **apic cloud-settings:update** - Update the Cloud Setting.
apic configured-gateway-services	Commands for Configured Gateway Services in a Catalog or Space.	• **apic configured-gateway-services** - Configured Gateway Services operations. • **apic configured-gateway-services:clear** - Delete all Configured Gateway Services from a Catalog or Space. • **apic configured-gateway-services:create** - Configure a Gateway Service in a Catalog or Space. • **apic configured-gateway-services:delete** - Delete a Configured Gateway Service from a Catalog or Space. • **apic configured-gateway-services:get** - Obtain the details of a Configured Gateway Service in a Catalog or Space. • **apic configured-gateway-services:list** - List the Configured Gateway Services in a Catalog or Space.
apic credentials	Credential commands	• **apic credentials** - Application Credential collection operations. • **apic credentials:clear** - Clear the Application Credentials. • **apic credentials:create** - Create a Application Credential. • **apic credentials:delete** - Delete the Application Credential by name or ID. • **apic credentials:get** - Get the Application Credential by name or ID. • **apic credentials:list** - List the Application Credentials. • **apic credentials:reset** - Reset the client id and client secret. • **apic credentials:reset-client-secret** - Reset the client secret. • **apic credentials:update** - Update the Application Credential by name or ID. • **apic credentials:verify-client-secret** - Verify the client secret.
apic extensions	Extension commands	• **apic extensions** - Extension collection operations. • **apic extensions:document** - Get the document for an extension by id, or by name and version. • **apic extensions:get** - Get an extension by id, or by name and version. • **apic extensions:list** - List all versions of an extension given the name. • **apic extensions:list-all** - List all versions of all extensions.
apic gateway-services	Gateway service commands	• **apic gateway-services** - Gateway Service collection operations. • **apic gateway-services:clear** - Clear the Gateway Services. • **apic gateway-services:create** - Create a Gateway Service. In order to enable AI Gateway on a DataPower API Gateway, set the property **ai_gateway_enabled** to **true**, else to **false**. • **apic gateway-services:delete** - Delete the Gateway Service by name or ID. • **apic gateway-services:get** - Get the Gateway Service by name or ID. • **apic gateway-services:list** - List the Gateway Services. • **apic gateway-services:reset-oauth-secret** - Reset the OAuth cryptographic • **apic gateway-services:update** - Update the Gateway Service by name or ID. In order to enable AI Gateway on a DataPower API Gateway, set the property **ai_gateway_enabled** to **true**, else to **false**.
apic integrations	Integrations commands	• **apic integrations** - Integration collection operations. • **apic integrations:clear** - Clear the Integrations. • **apic integrations:clear-all** - Clear all of the Integrations in all of the collections. • **apic integrations:create** - Create a Integration. • **apic integrations:delete** - Delete the Integration by name or ID. • **apic integrations:get** - Get the Integration by name or ID. • **apic integrations:list** - List the Integrations. • **apic integrations:list-all** - List all Integrations in all collections. • **apic integrations:update** - Update the Integration by name or ID.

Command	Description	Sub-commands
`apic keystores`	Keystores commands	• `apic keystores` - Keystore collection operations. • `apic keystores:clear` - Clear the Keystores. • `apic keystores:create` - Create a Keystore. • `apic keystores:delete` - Delete the Keystore by name or ID. • `apic keystores:get` - Get the Keystore by name or ID. • `apic keystores:list` - List the Keystores. • `apic keystores:update` - Update the Keystore by name or ID.
`apic mail-servers`	Mail server commands	• `apic mail-servers` - Mail Server collection operations. • `apic mail-servers:clear` - Clear the Mail Servers. • `apic mail-servers:create` - Create a Mail Server. • `apic mail-servers:delete` - Delete the Mail Server by name or ID. • `apic mail-servers:get` - Get the Mail Server by name or ID. • `apic mail-servers:list` - List the Mail Servers. • `apic mail-servers:test-connection` - Test a mail server connection. • `apic mail-servers:update` - Update the Mail Server by name or ID.
`apic notification-templates`	Notification template commands	• `apic notification-templates` - Notification Template collection operations. • `apic notification-templates:get` - Get the Notification Template by name or ID. • `apic notification-templates:list` - List the Notification Templates. • `apic notification-templates:list-all` - List all Notification Templates in all collections. • `apic notification-templates:update` - Update the Notification Template by name or ID.
`apic permissions`	Permissions commands	• `apic permissions` - Permission collection operations. • `apic permissions:get` - Get the Permission by name or ID. • `apic permissions:list` - List the Permissions. • `apic permissions:list-all` - List all Permissions in all collections.
`apic portal-services`	Portal services commands	• `apic portal-services` - Portal Service collection operations. • `apic portal-services:clear` - Clear the Portal Services. • `apic portal-services:create` - Create a Portal Service. • `apic portal-services:delete` - Delete the Portal Service by name or ID. • `apic portal-services:get` - Get the Portal Service by name or ID. • `apic portal-services:list` - List the Portal Services. • `apic portal-services:update` - Update the Portal Service by name or ID.
`apic services`	Services commands	• `apic services` - Service collection operations. • `apic services:clear` - Clear the Services. • `apic services:clear-all` - Clear all Services in all collections. • `apic services:create` - Create a Service. • `apic services:delete` - Delete a Service. • `apic services:get` - Get the Service by name and version. • `apic services:list` - List the Services. • `apic services:list-all` - List all Services in all collections. • `apic services:update` - Update the Service by name and version.
`apic space-settings`	Space settings commands	• `apic space-settings:get` - Get the Space Setting. • `apic space-settings:update` - Update the Space Setting.
`apic spaces`	Space commands	• `apic spaces` - Space collection operations. • `apic spaces:clear` - Clear the Spaces. • `apic spaces:create` - Create a Space. • `apic spaces:delete` - Delete the Space by name or ID. • `apic spaces:get` - Get the Space by name or ID. • `apic spaces:list` - List the Spaces. • `apic spaces:transfer-owner` - Transfer owner to a new member. • `apic spaces:update` - Update the Space by name or ID.
`apic tls-client-profiles`	TLS client profile commands	• `apic tls-client-profiles` - TLS Client Profile collection operations. • `apic tls-client-profiles:clear` - Clear the TLS Client Profiles. • `apic tls-client-profiles:clear-all` - Clear all of the TLS Client Profiles in the collection. • `apic tls-client-profiles:create` - Create a TLS Client Profile. • `apic tls-client-profiles:delete` - Delete the TLS Client Profile by name or ID. • `apic tls-client-profiles:get` - Get the TLS Client Profile by name or ID. • `apic tls-client-profiles:list` - List the TLS Client Profiles. • `apic tls-client-profiles:list-all` - Lists all of the TLS Client Profiles in a collection. • `apic tls-client-profiles:update` - Update the TLS Client Profile by name or ID.
`apic tls-server-profiles`	TLS server profile commands	• `apic tls-server-profiles` - TLS Server Profile collection operations. • `apic tls-server-profiles:clear` - Clear the TLS Server Profiles. • `apic tls-server-profiles:clear-all` - Clear all of the TLS Server Profiles in the collection. • `apic tls-server-profiles:create` - Create a TLS Server Profile. • `apic tls-server-profiles:delete` - Delete the TLS Server Profile by name or ID. • `apic tls-server-profiles:get` - Get the TLS Server Profile by name or ID. • `apic tls-server-profiles:list` - List the TLS Server Profiles. • `apic tls-server-profiles:list-all` - List all of the TLS Server Profiles in the collection. • `apic tls-server-profiles:update` - Update the TLS Server Profile by name or ID.

Command	Description	Sub-commands
`apic truststores`	Truststore commands	• `apic truststores` - Truststore collection operations. • `apic truststores:clear` - Clear the Truststores. • `apic truststores:create` - Create a Truststore. • `apic truststores:delete` - Delete the Truststore by name or ID. • `apic truststores:get` - Get the Truststore by name or ID. • `apic truststores:list` - List the Truststores. • `apic truststores:update` - Update the Truststore by name or ID.
`apic user-registries`	User registry commands	• `apic user-registries` - User Registry collection operations. • `apic user-registries:clear` - Clear the User Registries. • `apic user-registries:create` - Create a User Registry. • `apic user-registries:delete` - Delete the User Registry by name or ID. • `apic user-registries:execute` - Execute a User Registry operation. • `apic user-registries:get` - Get the User Registry by name or ID. • `apic user-registries:list` - List the User Registries. • `apic user-registries:search` - search for users in a user registry. • `apic user-registries:test-connection` - Test a User Registry connection. • `apic user-registries:update` - Update the User Registry by name or ID.
`apic user-registry-settings`	User registry settings commands	• `apic user-registry-settings:get` - Get the User Registry Setting. • `apic user-registry-settings:update` - Update the User Registry Setting.
`apic users`	Users commands	• `apic users` - User collection operations. • `apic users:clear` - Clear the Users. • `apic users:create` - Create a User. • `apic users:delete` - Delete the User by name or ID. • `apic users:get` - Get the User by name or ID. • `apic users:list` - List the Users. • `apic users:request-password-reset` - send a password reset link. • `apic users:search-provider` - Search for provider users from an organization. • `apic users:update` - Update the User by name or ID.
`apic webhooks`	Webhooks commands	• `apic webhooks` - Webhooks collection operations. • `apic webhooks:get` - Get the Webhooks by name or ID. • `apic webhooks:list` - List the Webhooks. • `apic webhooks:update` - Update the Webhooks by name or ID.

API development and management commands

A summary of the core commands in the IBM® API Connect developer toolkit.

Authenticating

Use the `apic login` command to authenticate to an API Manager service, and the `apic logout` command to remove your local authentication credentials.
Note: When you authenticate successfully, your credentials are stored, in plain text, in the file Linux .netrc or Windows _netrc. Therefore, you should set the file permissions in such a way that your credentials are not accessible by others.
For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Configuring the command-line tool to use TLS certificates

API Manager uses TLS profiles to secure data transmission. For information on how to create a TLS profile in API Manager, see TLS profiles.

To configure the toolkit command-line tool to use certificates to communicate with an API Manager that has TLS profiles that are enabled, follow these steps:

For more information about the NODE_EXTRA_CA_CERTS environment variable, see Node.js documentation.

Creating and managing local files

You create and work with API and Product definition YAML files locally before you stage them to API Manager.

To create a local API definition file, use the `apic create:api` command. To create a local Product definition file, use the `apic create:product` command.

Use the `apic apis` and `apic products` commands to list API Manager artifacts of the specified type.

To validate the syntactical correctness of a local API or Product definition file, use the `apic validate` command.

To create a draft API in API Manager from a local API or Product definition file, use the `apic draft-apis:create` and `apic draft-products:create` commands, respectively.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before an API is validated, created in draft, staged, or published. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Working with Catalogs and Spaces

To create a Catalog, use the **apic catalog:create** command. To view information on a Catalog, use the **apic catalog:get** command; to list all Catalogs that are contained in organizations that the currently authenticated user is a member of, use the **apic catalogs** command.

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see Using syndication in IBM API Connect.

To enable Spaces for a Catalog, use the following command:

apic catalogs:set *catalog_name* --spaces enabled

Use the toolkit **apic spaces** commands to create and manage Spaces:

- **apic spaces** - List Spaces contained in a Catalog.
- **apic:spaces create** - Create a Space in a Catalog.
- **apic:spaces get** - Get information on a Space in a Catalog.
- **apic:spaces set** - Set information on a Space in a Catalog.
- **apic:spaces delete** - Delete a Space in a Catalog.

Command summary

The following tables summarize **apic** commands for API development and management.

Table 1. Summary of general-purpose commands

Command	Description	Subcommands
apic config	List and manage configuration variables. For more information, see Using configuration variables. With no subcommand, lists values of defined configuration variables.	• **apic config** - Manage configuration variables • **apic config:clear** - Delete all configuration variables • **apic config:delete** - Delete a configuration variable • **apic config:get** - Get a configuration variable • **apic config:list** - List the application and global configuration variables • **apic config:set** - Set or update configuration variables
apic create	Create a draft API or Product definition YAML file.	• **create:api** - Create a draft API OpenAPI definition YAML file • **create:product** - Create a Product definition YAML file
apic extensions	Manage OpenAPI extensions in a Catalog. With no subcommand, lists the extensions in the production Catalog.	• **apic extensions** - Extension collection operations. • **apic extensions:clear** - Delete all versions of an extension given the name. • **apic extensions:clear-all** - Delete all versions of all extensions. • **apic extensions:clone** - Download all versions of all extensions to your local drive. • **apic extensions:create** - Create an extension. • **apic extensions:delete** - Delete an extension by ID, or by name and version. • **apic extensions:document** - Get the document for an extension by ID, or by name and version. • **apic extensions:get** - Get an extension by ID, or by name and version. • **apic extensions:list** - List all versions of an extension given the name. • **apic extensions:list-all** - List all versions of all extensions. • **apic extensions:update** - Update an extension by ID, or by name and version.
apic login	Log in to API Manager.	None. Specify server and credentials with the required flags: • **-p, --password** *password* • **-r, --realm** *realm*. Determines the identity provider that is used to authenticated the supplied user ID, and the scope of the tasks that can be performed after successful log in. • **-s, --server** *mgmt_endpoint_url*. Use the value of the platform API endpoint URL for this entry. • **-u, --username** *user_name* For full details on how to log in to your management server from the CLI, see Logging in to the management server.
apic logout	Log out from API Manager.	None. Specify server with the required flag: • **-s, --server** *mgmt_service*. You can append the port number to the server name if it is not the default value of 443.
apic validate	Validate API or Product definition YAML file.	None

Table 2. Summary of commands to manage APIs, Products, and Catalogs

Command	Description	Subcommands
apic apis	List and manage APIs that are staged or published to Catalog or Space. Default subcommand is **list-all**.	• **apic apis** - API collection operations • **apic apis:get** - Get the OpenAPI definition YAML file for an API by name and version, or by ID • **apic apis:list** - List an API by name • **apic apis:list-all** - List all APIs in a Catalog or Space • **apic apis:update** - Update an API by name

Command	Description	Subcommands
`apic apps`	List and manage developer applications that are registered in a consumer organization. Default subcommand is `list`.	• `apic apps` - Application collection operations • `apic apps:clear` - Clear all applications • `apic apps:create` - Create an application • `apic apps:delete` - Delete an application by name or ID • `apic apps:get` - Get an application object by name • `apic apps:list` - List all the applications in a consumer organization • `apic apps:update` - Update an application by name or ID
`apic catalogs`	List and manage Catalogs in a provider organization. Default subcommand is `list`.	• `apic catalogs:clear` - Clear all Catalogs from provider organization • `apic catalogs:create` - Create a Catalog • `apic catalogs:delete` - Delete a Catalog by name or ID • `apic catalogs:get` - Get a Catalog object by name or ID • `apic catalogs:list` - List all the Catalogs in a provider organization • `apic catalogs:transfer-owner` - Transfer the ownership of a Catalog to another user • `apic catalogs:update` - Update a Catalog by name or ID
`apic catalog-settings`	Manage the configuration settings for a Catalog	• `apic catalog-settings:get` - Get the Catalog settings. • `apic catalog-settings:update` - Update the Catalog settings.
`apic drafts`	List and manage the draft API and Product definitions in a provider organization. Default subcommand is `list`.	• `apic drafts` - Draft collection operations • `apic drafts:clear` - Delete all draft APIs and Products in a provider organization • `apic drafts:list` - List the draft APIs and Products in a provider organization
`apic draft-apis`	List and manage the draft API definitions in a provider organization. Default subcommand is `list-all`.	• `apic draft-apis` - Draft API collection operations • `apic draft-apis:clear` - Delete all versions of a draft API by name • `apic draft-apis:clear-all` - Delete all draft APIs in a provider organization • `apic draft-apis:clone` - Clone all draft APIs in a provider organization • `apic draft-apis:create` - Create a draft API • `apic draft-apis:delete` - Delete a Draft API by name and version • `apic draft-apis:document` - Get the Draft API document by name and version • `apic draft-apis:get` - Get the OpenAPI definition YAML file for an API by name and version • `apic draft-apis:list` - List all versions of a draft API by name • `apic draft-apis:list-all` - List all draft APIs in a provider organization • `apic draft-apis:update` - Update a draft API by name and version, supplying the revised OpenAPI definition file • `apic draft-apis:update-wsdl` - Update a draft SOAP API by name and version, supplying the revised WSDL definition file in a .wsdl or .zip format Note: There must be a match of the service names in the existing WSDL with the revised WSDL. If a match is found, the WSDL service is converted into a YAML file that is used to update the API. If no match is found, an error message is displayed. • `apic draft-apis:validate` - Validates a draft API • `apic draft-apis:wsdl` - Get the Draft API WSDL document by name and version
`apic draft-products`	List and manage the draft Product definitions in a provider organization. Default subcommand is `list-all`.	• `apic draft-products` - Draft Product collection operations • `apic draft-products:clear` - Delete all versions of a draft Product by name • `apic draft-products:clear-all` - Delete all draft Products in a provider organization • `apic draft-products:create` - Create a draft Product • `apic draft-products:delete` - Delete a draft Product by name and version • `apic draft-products:get` - Get the Draft Product by name and version • `apic draft-products:list` - List the Draft Products • `apic draft-products:list-all` - List all draft Products in a provider organization • `apic draft-products:publish-all` - Publishes the Draft Product • `apic draft-products:update` - Update a draft Product by name and version, supplying the revised definition file • `apic draft-products:validate` - Validates a draft Product
`apic members`	List and manage the members of a provider organization, consumer organization, Catalog, or Space. Default subcommand is `list`.	• `apic members` - Member operations • `apic members:clear` - Delete all members • `apic members:create` - Create a member • `apic members:delete` - Delete a member by name or ID • `apic members:get` - Get a member object by name or ID • `apic members:list` - List all members • `apic members:update` - Update the member by name or ID
`apic member-invitations`	List and manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space. Default subcommand is `list`.	• `apic member-invitations` - Member invitation collection operations. • `apic member-invitations:clear` - Delete all member invitations. • `apic member-invitations:create` - Create a member invitation. • `apic member-invitations:delete` - Delete a member invitation by name or ID. • `apic member-invitations:get` - Get a member invitation object by name or ID. • `apic member-invitations:list` - List all member invitations. • `apic member-invitations:update` - Update a member invitation by name or ID.

Command	Description	Subcommands
`apic orgs`	List and manage provider organizations, and the admin organization. Default subcommand is `list`.	• `apic orgs` - Organization collection operations • `apic orgs:clear` - Delete all organizations • `apic orgs:create` - Create an organization • `apic orgs:delete` - Delete an organization by name or ID • `apic orgs:get` - Get an organization object by name or ID • `apic orgs:list` - List all organizations • `apic orgs:transfer-owner` - Transfer ownership of an organization • `apic orgs:update` - Update an organization by name or ID
`apic org-settings`	Manage settings for provider organizations, and the admin organization.	• `apic org-settings:get` - Get the settings object for an organization • `apic org-settings:update` - Update the settings for an organization
`apic policies`	List and manage policies in a Catalog. Default subcommand is `list`.	• `apic policies` - Policy collection operations • `apic policies:clear` - Clear the Policies • `apic policies:clear-all` - Clear all Policies in all collections • `apic policies:create` - Create a Policy • `apic policies:delete` - Delete a Policy • `apic policies:get` - Get the Policy by name and version • `apic policies:list` - List the Policies • `apic policies:list-all` - List all Policies in all collections • `apic policies:update` - Update the Policy by name and version
`apic products`	List and manage Products that are staged or published to Catalog or Space. Default subcommand is `list-all`.	• `apic products` - Product collection operations • `apic products:clear` - Delete all versions of a Product by name • `apic products:clear-all` - Delete all Products • `apic products:delete` - Delete a Product by name and version • `apic products:execute-migration-target` - Products execute migration target operations • `apic products:get` - Get a Product object by name and version • `apic products:list` - List all versions of a Product by name • `apic products:list-all` - List all Products • `apic products:publish` - Publish a Product to a Catalog or Space, supplying the Product definition YAML file • `apic products:replace` - Replace a Product with another Product • `apic products:set-migration-target` - Set the target Product for migrating subscriptions from a Product • `apic products:supersede` - Supersede a Product with another Product • `apic products:update` - Update a Product by name and version, supplying the revised Product definition YAML file
`apic identity-providers`	View information about identity providers.	• `apic identity-providers` - Identity provider operations • `apic identity-providers:list` - List the identity providers.
`apic spaces`	List and manage Spaces contained in a Catalog. Default subcommand is `list`.	• `apic spaces` - Space collection operations • `apic spaces:clear` - Delete all Spaces from a Catalog • `apic spaces:create` - Create a Space in a Catalog • `apic spaces:delete` - Delete a Space from a Catalog, by name or ID • `apic spaces:get` - Get a Space object by name or ID • `apic spaces:list` - List all the Spaces in a Catalog • `apic spaces:transfer-owner` - Transfer the ownership of a Space to another user • `apic spaces:update` - Update a Space by name or ID
`apic subscriptions`	List and manage subscriptions in a Product or a Catalog. Default subcommand is `list`.	• `apic subscriptions` - Subscription collection operations • `apic subscriptions:clear` - Clear the Subscriptions • `apic subscriptions:create` - Create a Subscription • `apic subscriptions:delete` - Delete the Subscription by name or ID • `apic subscriptions:get` - Get the Subscription by name or ID • `apic subscriptions:list` - List the Subscriptions • `apic subscriptions:update` - Update the Subscription by name or ID

Table 3. Summary of other commands for API developers and managers

Command	Description	Subcommands
`apic consumer-orgs`	Manage consumer organizations	• `apic consumer-orgs` - Consumer Organization collection operations. • `apic consumer-orgs:clear` - Clear the Consumer Organizations. • `apic consumer-orgs:create` - Create a Consumer Organization. • `apic consumer-orgs:delete` - Delete the Consumer Organization by name or ID. • `apic consumer-orgs:get` - Get the Consumer Organization by name or ID. • `apic consumer-orgs:list` - List the Consumer Organizations. • `apic consumer-orgs:transfer-owner` - Transfer owner to a new member. • `apic consumer-orgs:update` - Update the Consumer Organization by name or ID.

Command	Description	Subcommands
`apic consumer-org-settings`	Manage consumer organization settings	• `apic consumer-org-settings:delete` - Delete the Consumer Organization Setting. • `apic consumer-org-settings:get` - Get the Consumer Organization Setting. • `apic consumer-org-settings:update` - Update the Consumer Organization Setting.
`apic groups`	Manage groups	• `apic groups` - Group collection operations. • `apic groups:clear` - Clear the Groups. • `apic groups:create` - Create a Group. • `apic groups:delete` - Delete the Group by name or ID. • `apic groups:get` - Get the Group by name or ID. • `apic groups:list` - List the Groups. • `apic groups:update` - Update the Group by name or ID.
`apic invitations`	Manage invitations. An invitation is created when a user is invited to be the owner of a provider organization, consumer organization, Catalog, or Space.	• `apic invitations` - Invitation collection operations. • `apic invitations:clear` - Delete all invitations. • `apic invitations:create` - Create an invitation. • `apic invitations:delete` - Delete an invitation by name or ID. • `apic invitations:get` - Get the details of an invitation by name or ID. • `apic invitations:list` - List all invitations. • `apic invitations:update` - Update an invitation by name or ID.
`apic member-invitations`	Manage member invitations. A member invitation is created when a user is invited to be a member of a provider organization, consumer organization, Catalog, or Space.	• `apic member-invitations` - Member invitation collection operations. • `apic member-invitations:clear` - Delete all member invitations. • `apic member-invitations:create` - Create a member invitation. • `apic member-invitations:delete` - Delete a member invitation by name or ID. • `apic member-invitations:get` - Get the details of a member invitation by name or ID. • `apic member-invitations:list` - List all member invitations. • `apic member-invitations:update` - Update a member invitation by name or ID.
`apic members`		• `apic members` - Member collection operations. • `apic members:clear` - Clear the Members. • `apic members:create` - Create a Member. • `apic members:delete` - Delete the Member by name or ID. • `apic members:get` - Get the Member by name or ID. • `apic members:list` - List the Members. • `apic members:update` - Update the Member by name or ID.
`apic registrations`		• `apic registrations` - Registration collection operations. • `apic registrations:clear` - Clear the Registrations. • `apic registrations:create` - Create a Registration. • `apic registrations:delete` - Delete the Registration by name or ID. • `apic registrations:get` - Get the Registration by name or ID. • `apic registrations:list` - List the Registrations. • `apic registrations:update` - Update the Registration by name or ID.
`apic role-defaults`		• `apic role-defaults` - Role Default collection operations. • `apic role-defaults:clear` - Clear the Role Defaults. • `apic role-defaults:create` - Create a Role Default. • `apic role-defaults:delete` - Delete the Role Default by name or ID. • `apic role-defaults:get` - Get the Role Default by name or ID. • `apic role-defaults:list` - List the Role Defaults. • `apic role-defaults:list-all` - List all Role Defaults in all collections. • `apic role-defaults:update` - Update the Role Default by name or ID.
`apic roles`		• `apic roles` - Role collection operations. • `apic roles:clear` - Clear the Roles. • `apic roles:create` - Create a Role. • `apic roles:delete` - Delete the Role by name or ID. • `apic roles:get` - Get the Role by name or ID. • `apic roles:list` - List the Roles. • `apic roles:update` - Update the Role by name or ID.
`apic tasks`		• `apic tasks` - Task collection operations. • `apic tasks:clear` - Clear the Tasks. • `apic tasks:create` - Create a Task. • `apic tasks:delete` - Delete the Task by name or ID. • `apic tasks:get` - Get the Task by name or ID. • `apic tasks:list` - List the Tasks. • `apic tasks:update` - Update the Task by name or ID.

Command	Description	Subcommands
`apic user-registries`		• `apic user-registries` - User Registry collection operations. • `apic user-registries:clear` - Clear the User Registries. • `apic user-registries:create` - Create a User Registry. • `apic user-registries:delete` - Delete the User Registry by name or ID. • `apic user-registries:execute` - Execute a User Registry operation. • `apic user-registries:get` - Get the User Registry by name or ID. • `apic user-registries:list` - List the User Registries. • `apic user-registries:search` - search for users in a user registry. • `apic user-registries:test-connection` - Test a User Registry connection. • `apic user-registries:update` - Update the User Registry by name or ID.
`apic user-registry-settings`		• `apic user-registry-settings:delete` - Delete the User Registry Setting. • `apic user-registry-settings:get` - Get the User Registry Setting. • `apic user-registry-settings:update` - Update the User Registry Setting.
`apic users`		• `apic users` - User collection operations. • `apic users:clear` - Clear the Users. • `apic users:create` - Create a User. • `apic users:delete` - Delete the User by name or ID. • `apic users:get` - Get the User by name or ID. • `apic users:list` - List the Users. • `apic users:request-password-reset` - send a password reset link. • `apic users:search-provider` - Search for provider users from an organization. • `apic users:update` - Update the User by name or ID.
`apic test`	Test your APIs	• `apic test {yaml-files}` - Define the tests. • `apic test {yaml-files} --insecureSkipVerify` - Test the APIs with certificate checks disabled. • `apic test {yaml-files} --certPath={location of certs folder}` - Specifies the location of the CA certificate if it is not available in the system keystore. • `api test {yaml-files} --mTLS --certPath={location of certs folder}` - Test the APIs with `mTLS` enabled. • `api test {yaml-files} --config-file={location of config file}` - Define the tests by passing the external configuration.

Creating APIs and applications

You can develop API proxies and API implementations by using the developer toolkit. In the documentation, *API* refers to the API proxy and *application* refers to the API implementation.

You can use the developer toolkit to create language-independent APIs by using OpenAPI to proxy to an existing backend implementation or to augment applications that are developed in other languages or frameworks such as Express, Java™, Swift, Go, and others.

Creating development artifact definitions

Use the `apic create` command to create development artifacts, by using the following commands:

Command	Description
`apic create:api`	Create an OpenAPI definition.
`apic create:api --wsdl filename`	Create a SOAP API definition from a WSDL definition file, or a .zip file that contains the WSDL definition files for a service. The name and version of the generated API are obtained from the WSDL file. If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.
`apic create:product`	Create an API Product definition.

Note: You can create an API or Product from an OpenAPI template file by using the `--template template-name` option.
You can also create Product and API definitions non-interactively by providing the `--title` option. This option sets several values that you can also customize with additional options; for example:

```
apic create:api --title Routes
apic create:product --title "Climb On"
```

You can also create the API and Product definitions at the same time:

```
apic create:api --title Routes --product "Climb On"
apic create:api --wsdl globalweather.wsdl --product "Weather Forecasting"
```

Alternatively, you can create APIs and then reference them when you create a new Product; for example:

```
apic create:api --title Routes
apic create:api --title Ascents
```

```
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
```

Validating development artifact definitions

After you edit development artifacts or before you publish artifacts, best practice is to validate them; for example:

```
apic validate routes.yaml                     # Validate an API
apic validate climb-on.yaml                   # Validate the Product and its APIs
apic validate climb-on.yaml --product-only    # Validate the Product only (do not validate the referenced APIs)
```

Note: If the OpenAPI file that defines your API uses a **$ref** field to reference a fragment of OpenAPI code that is defined in a separate file,the **$ref** field is replaced with the contents of the target file before the draft API is created with the **apic drafts:validate** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Publishing APIs and applications

To publish APIs and applications by using the developer toolkit of IBM® API Connect, you set configuration variables to define where you want to publish, log in to the target cloud platform, and then use the appropriate publishing commands.

See the following sections for more information:

- Setting configuration variables
- Logging in to API Connect
- Publishing APIs

Setting configuration variables

The **apic config** command provides global and project-based configuration variables that specify the target Catalog for publishing APIs and applications. The values of these variables are stored in **~/.apiconnect/config** (for global variables) and ***project-dir*/.apiconnect** (for project variables). For a full list of configuration variables, see Overview of the command-line tool.

Set the **catalog** configuration variable to the URI of an API Connect Catalog to define a default Catalog target for all commands managing Catalogs. The **catalog** URI has the form:

https://*mgmt_endpoint_url*/api/catalogs/*org_name*/*catalog_name*

where *mgmt_endpoint_url* is the platform API endpoint URL, *org_name* is the provider organization name, and *catalog_name* is the Catalog name. The *mgmt_endpoint_url* portion sets the default value of the **--server** option, the *org_name* portion sets the default value of the **--org** option, and the *catalog_name* portion sets the default value of the **--catalog** option; you can override any of these values by including the corresponding option in a command.

Set the **space** configuration variable to the URI of an API Connect Space, to define a default Space target for all commands that manage Spaces. The **space** URI has the form:

https://*mgmt_endpoint_url*/api/spaces/*org_name*/*catalog_name*/*space_name*

where *mgmt_endpoint_url* is the platform API endpoint URL, *org_name* is the provider organization name, *catalog_name* is the Catalog name, and *space_name* is the name of the Space. The *mgmt_endpoint_url* portion sets the default value of the **--server** option, the *org_name* portion sets the default value of the **--org** option, the *catalog_name* portion sets the default value of the **--catalog** option, and the *space_name* sets the default value of the **--space** option; you can override any of these values by including the corresponding option in a command.
Although setting these configuration variables is not required, doing so simplifies commands that interact with API Connect clouds by providing default values for frequently used command-line options.

Here is an example of publishing with and without the **catalog** configuration variable set.

Without the configuration variable set:

```
apic products publish climb-on.yaml --server mgmnthost.com --org climbon --catalog sandbox
```

With the configuration variable set:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
catalog: https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic products publish climb-on.yaml
```

You can override default values provided by the **catalog** configuration variable by providing one of the standard options with a different value. For example, use the **--catalog** option with the **apic products publish** command to specify the **qa** Catalog:

```
 apic products publish climb-on.yaml --catalog qa
```

Don't forget about global configuration variables. If you use the same Catalog as the default target for multiple projects, set the value globally:

```
 apic config:set --global catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
```

Note:
If you have an environment variable of the same name as a CLI configuration property then, by default, its value will override the value of the corresponding CLI configuration property for any CLI command at that scope.

For example, if you have defined an environment variable called **SPACE** then, by default, that value will be assumed for the value of the **--space** parameter in the following command, regardless of any **space** configuration property setting:

```
apic products:publish my_product.yaml --scope space
```

To prevent environment variables overriding CLI configuration properties, define an environment variable called **APIC_LOAD_FROM_ENV**, set to the value **false**.

Logging in to API Connect

Use the **apic login** and **apic logout** commands to manage your authentication. For details, see Logging in to a management server.

Publishing APIs

Publishing APIs to API Catalogs in API Connect clouds enables you to socialize the APIs by using the developer portal and secure them by using the Gateway.

An *API Product* (or simply *Product*) is used to compose APIs for publishing. API Product managers can use it to bundle one or more APIs together, control the visibility of the Product in the developer portal (for example, only allow partners x, y, and z to view and subscribe to the Product), and define Plans to provide consumption options. The Products that reference the APIs and define the consumption Plans are also the primary unit of lifecycle management for APIs.

Use the **apic products publish** command (equivalent to **apic products:publish**) to publish API Products to an API Connect cloud. The following example demonstrates how to create APIs composed by a Product, and publishing the Product and its APIs to a Catalog:

```
apic create:api --title Routes
apic create:api --title Ascents
apic create:product --title "Climb On" --apis "routes.yaml ascents.yaml"
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/default-idp-2
apic products publish climb-on.yaml
```

For full details on how to log in to your management server from the CLI, see Logging in to a management server.

Add the **--stage** option to **apic publish** to stage the Product into a Catalog instead of publishing it. Products in a Catalog can be in the following states: staged, published, deprecated, or retired. For example:

```
apic products publish --stage climb-on.yaml
```

You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see Using syndication in IBM API Connect.

If default configuration values have been set for the Space, Catalog, organization and management server, the following publish command could be used:

```
apic products publish --scope space product.yaml
```

where *product* is the name of the product that you want to publish.
Note: If the OpenAPI file that defines your API uses a **$ref** field to reference a fragment of OpenAPI code that is defined in a separate file, the **$ref** field is replaced with the contents of the target file before the Product that contains the API is staged or published with the **apic publish** command. For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Managing API Products

Use the **apic products** and **apic apis** commands to manage Products and APIs that have been published to IBM® API Connect Catalogs. Use the **--scope space** option to manage Products and APIs that have been published to Spaces within Catalogs.

Product management command summary

The following table summarizes the commands available for managing API Products. Usage examples follow.

Example command	Description
`apic config:set catalog=https://platform-api.myserver.com/api/catalogs/myorg/sandbox`	Set the default Catalog.
`apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/my-identity-provider`	Login into the management server. For full details on how to log in to your management server from the CLI, see Logging in to the management server.
`apic create:api --title Routes --product "ClimbOn"`	Create the Product and API.
`apic products:publish climbon.yaml`	Publish the Product to the default catalog. Add --stage argument to stage the Product.
`apic products:list-all --scope catalog`	List the Products in the default catalog.
`apic products:get climbon:1.0.0 --output -`	Display the Product's properties. Omit the output argument to download to a file.
`apic apis:list-all --scope catalog`	List the APIs in the Catalog.
`apic apis:get routes:1.0.0 --output -`	Get the API properties. Omit the output argument to download to a file.
`apic products:replace climbon:1.0.0 mapfile.txt`	Replace the Product indicated on the command line with the staged or published Product designated in the mapfile. This retires the replaced Product.
`apic products:supersede climbon:1.0.0 mapfile.txt`	Supersede the Product indicated on the command line with the staged or published Product designated in the mapfile. This deprecates the superseded Product.
`apic products:delete climbon:1.0.0`	Delete the Product from the Catalog. The Product must be either retired or deprecated.

Using the `products` and `apis` commands through a full lifecycle

This example shows a complex lifecycle where a new version of a Product and API replaces the original version at run time.

Note: If the OpenAPI file that defines your API uses a **$ref** field to reference a fragment of OpenAPI code that is defined in a separate file, the **$ref** field is replaced with the contents of the target file before the Product that contains the API is staged or published with the **apic publish** command. For more information, see Using $ref to

reuse code fragments in your OpenAPI files.

Set the default Catalog and login to the mgmnthost.com API Connect cloud

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox
apic login --username some-user --password some-password --server platform-api.myserver.com --realm my-identity-provider
```

For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Create and publish an initial version

```
apic create:api --title Routes --version 1.0.0 --filename routes100.yaml
apic create:product --title "Climb On" --version 1.0.0 --apis routes100.yaml --filename climbon100.yaml
apic products:publish climbon100.yaml
```

Create a new version to fix a bug in the API, stage it to the Catalog

```
apic create:api --title Routes --version 1.0.1 --filename routes101.yaml
apic create:product --title "Climb On" --version 1.0.1 --apis routes101.yaml --filename climbon101.yaml
apic products:publish --stage climbon101.yaml
```

Inspect the Catalog

```
apic products:list-all --scope catalog
```

This produces a list of all Products in the catalog. Copy the ID of the `climbon:1.0.1` Product. The ID resembles the following example.

```
https:/server/api/catalogs/3eca6046-3c27-4ad/ab8772bf-0f65-45/products/8f854623-bda1-4f9
```

Create a mapping file

For example, if you are replacing a Product, the mapping file specifies the Product that you want to replace, and the mapping of the Plans from the source Product to the target Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then `product_url` property specifies the URL of `climbon:1.0.0`. This file takes the following form:

```
product_url: https:/server/api/catalogs/{id}/products/{id}
plans:
- source: {source_plan_name_1}
  target: {target_plan_name_1}
- source: {source_plan_name_2}
  target: {target_plan_name_2}
            .
            .
            .
```

Note:

- The source and target Plan names can be the same or different.
- Every Plan in the Product you are replacing must be mapped to a Plan in the replacement Product.

"Hot-replace" version 1.0.0 with 1.0.1

```
apic products:replace climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

After it is replaced in this way, a Product is retired. It is no longer active.
Note: The Product specified on the command line is the replacement Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then the Product specified on the command line is `climbon:1.0.1`.

Supersede version 1.0.0 with 1.0.1

Rather than hot-replacing an existing Product with a new one (usually an updated version), you can supersede the existing Product with a new one. When you replace a Product, all external application subscriptions to that Product are automatically moved to the new Product. When you supersede a Product, the subscriptions are not automatically moved to the new Product, some action must be taken to subscribe external applications to the superseding Product.
The command to supersede a Product uses the same mapping file as the command to replace a Product. The name of the superseding Product is given on the command line.

```
apic products:supersede climbon:1.0.1 PRODUCT_PLAN_MAPPING_FILE
```

Once superseded, a Product is marked deprecated, meaning that no further subscriptions to the Product are allowed, although it is still active and existing subscriptions still work.
Note: The Product specified on the command line is the superseding Product. For example, if you are replacing `climbon:1.0.0` with `climbon:1.0.1` then the Product specified on the command line is `climbon:1.0.1`. The mapping file specifies the URL of the Product you are superseding.

Set a migration target

It is possible to set a migration target for the existing Product. This helps migration.
Use a command like the following to set the migration target.

```
apic products:set-migration-target climbon:1.0.0 PRODUCT_PLAN_MAPPING_FILE
```

Note: The Product specified on the command line is the Product from which you want to migrate subscriptions. The mapping file specifies the target Product for the subscriptions.
Once a migration target is set, external application developers will be able to migrate their application subscriptions through the Developer Portal with ease. It is also possible to execute a subscription migration using the following command.

```
apic products:execute-migration-target climbon:1.0.0
```

Delete a Product

When the replaced or superseded Product is no longer needed, it can be deleted.

```
apic products:delete climbon:1.0.0
```

Additional Product and API operations

In addition to the lifecycle management capabilities, you can download Products and APIs in a catalog or space using the **clone** sub-command:

Command	Description
apic products:clone	Download all Products and their APIs from the catalog or space.
apic apis:clone	Download all APIs from the catalog or space.

It can also be useful to clear all Products and their APIs from a Catalog, particularly for a development Catalog (you must provide the name of the Catalog as the value of the **--confirm** parameter):

```
apic products:clear --confirm catalog_name
```

where *catalog_name* is the name of the Catalog.
You can use a *Space* to partition a Catalog so multiple teams can manage Products and APIs independently in a single Catalog. A Space is conceptually like a subcatalog, except that Products and APIs in all Spaces in a given Catalog are published to the same developer portal. For more information about Spaces, see Using syndication in IBM API Connect.

To manage the Products and APIs that have been published to a Space, include the **--scope space** option with the **apic products** and **apic apis** commands. For example, to list the Products that are contained in a Space called *flights*, use the following command:

```
apic products --scope space --space flights --catalog production --org climbonorg --server platform-api.myserver.com
```

Changing the lifecycle state of a Product in a Catalog or Space

To directly change the lifecycle state of a Product that has previously been staged or published to a Catalog or Space, complete the following steps:

- Enter the following command (the terminating hyphen character means that the command takes input from the command line):

  ```
  apic products:update product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space] -
  ```

  where:
  - *product_name* is the name of the Product whose lifecycle state you want to change.
  - *version* is the version of that Product.
  - *mgmt_endpoint_url* is the platform API endpoint URL.
  - *organization* is the name of the provider organization in which the Product was previously staged or published.
  - *scope* has one of the following values:
    - **catalog** if the Catalog does not have Spaces enabled.
    - **space** if the Catalog has Spaces enabled. If you specify **space** for the **--scope** parameter you must also supply the **--space** parameter.
  - *catalog* is the name of the Catalog in which the Product was previously staged or published.
  - (optional) *space* is the name of the Space. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command.

  The command returns:

  ```
  Reading PRODUCT_FILE arg from stdin
  ```

- Enter the following data, followed by a new line:

  ```
  state: new_state
  ```

  where *new_state* is the state that you want to change the Product to, and must have one of the following values.
  - staged
  - published
  - deprecated
  - retired
  - archived
- Press **CTRL D** to terminate the input. If the command is successful, the lifecycle state change is confirmed.
  For example:

  ```
  apic products:update finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox -
  Reading PRODUCT_FILE arg from stdin
  state: published
  finance:1.0.0    [state: published]   https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
  ```

Note:
The command will not succeed if the lifecycle state change you are attempting is not permitted.

For example, the following lifecycle state changes are permitted:

- staged to published
- deprecated to retired

The following lifecycle state changes are not permitted:

- published to staged
- retired to published

For full details, see The Product lifecycle.

To list all Products in a Catalog or Space, together with their lifecycle states, use the following command:

```
apic products:list-all --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space]
```

For example:

```
apic products:list-all --server https://myserver.com --org development --scope catalog --catalog sandbox
graphql-services:1.0.0    [state: staged]      https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-9e82-427a-abe6-be5b126210f7/products/7652d568-b396-4bfa-bf71-2f18cea63737
finance:1.0.0             [state: published]   https://myserver.com/api/catalogs/dce12994-a6a1-487b-83b6-c73bd8498799/006827d5-9e82-427a-abe6-be5b126210f7/products/0f0af980-f505-4f36-b09c-d7b1c9c1a2f2
```

To find out the lifecycle state of a specific Product, use the following command:

```
apic products:get product_name:version --server mgmt_endpoint_url --org organization --scope scope --catalog catalog [--space space] --fields state --output -
```

For example:

```
apic products:get finance:1.0.0 --server https://myserver.com --org development --scope catalog --catalog sandbox --fields state --output -
state: published
```

Example scripts

A set of example toolkit scripts that demonstrate how to create and manage organizations, users, apps, Products and APIs are available at https://github.com/ibm-apiconnect/example-toolkit-scripts.

Working with Drafts

Co-locate your APIs and applications in your local source code control systems to support typical development activities such as commits, branching, merges, continuous integration, and so on. The developer toolkit provides the bridge from the developer's environment to the IBM® API Connect runtime services.

API Connect provides an online development capability called *Drafts* where you can define API and Product definitions. The **apic drafts** commands enable synchronization of Product and API artifacts between local source code control systems and drafts.

You can use **drafts** to clear and list your drafts. For example:

```
apic config:set catalog=https://platform-api.myserver.com/api/catalogs/climbon/sandbox    # set the default Catalog
apic login --username some-user --password some-password --server platform-api.myserver.com --realm provider/myldap  # login into the management server

apic create:api --title routes --product ClimbOn
apic drafts                                          # list what is in drafts
apic drafts:clear --confirm drafts                   # clear drafts collection
apic drafts:list                                     # list the available drafts
```

For full details on how to log in to your management server from the CLI, see Logging in to the management server.

Reading input from the command line

If a developer toolkit command takes a file as an input parameter, you can direct the command to read the input directly from the command line rather than supplying a separate file; this can be useful when writing scripts to automate command line operations, for example.

Reading input from a file

Many developer toolkit commands that create or update new objects in API Connect take a file as an input parameter. For example:

- Register a new gateway service:

  ```
  apic gateway-services:create [flags] GATEWAY_SERVICE_FILE
  ```

- Update a provider organization:

  ```
  apic orgs:update [flags] ORG_FILE
  ```

- Create a new Catalog:

  ```
  apic catalogs:create [flags] CATALOG_FILE
  ```

- Create a new consumer organization:

  ```
  apic consumer-orgs:create [flags] CONSUMER_ORG_FILE
  ```

- Register a new developer application:

  ```
  apic apps:create [flags] APP_FILE
  ```

- Create a new email server:

  ```
  apic mail-servers:create [flags] MAIL_SERVER_FILE
  ```

- Update the list of applications that subscribe to a Product:

  ```
  apic subscriptions:update [flags] SUBSCRIPTION_FILE
  ```

You can format the input file as a YAML file (the default) or as a JSON file. To use a JSON file as input, include the **--format json** parameter.

Reading input from the command line

As an alternative to supplying an explicit file name to the command, you can supply a hyphen (-) in place of the file name parameter; the command will then read the file content directly from the command line as shown in the following examples.

- Register a new DataPower® Gateway (v5 compatible) gateway service:

```
apic gateway-services:create --server platform-api.myserver.com --org admin --availability-zone availability-zone-default
-
Reading GATEWAY_SERVICE_FILE arg from stdin
name: dpgw-service
title: DataPower gateway service, compatible with v5
gateway_service_type: datapower-gateway
endpoint: 'https://mygwhost.com:3000'
api_endpoint_base: 'https://mygwhost.com:9443'
sni:
  - host: '*'
    tls_server_profile_url: https://platform-api.myserver.com/api/orgs/75203636-f038-4287-a732-24af4bf7059d/tls-server-
profiles/3c0a0e93-6aa4-4288-b09c-eccf4901b104
visibility:
  type: public
```

  Note: You can obtain the `tls_server_profile_url` property value for a TLS server profile by using the following command, which lists the URLs for all TLS server profiles:

```
apic tls-server-profiles --org organization_name --server mgmt_endpoint_url
```

- Create a new provider organization:

```
apic orgs:create --server platform-api.myserver.com -
Reading ORG_FILE arg from stdin
name: development
title: Development organization
owner_url: https://platform-api.myserver.com/api/user-registries/1bbbd414-22f1-47cf-8eac-2050530d29a7/c082d755-866e-4394-
959f-fbb264c6c3a1/users/2db491c7-2d0f-4f60-a8ae-f38d07481f21
```

  Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

```
apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url
--output -
```

- Create a new Catalog:

```
apic catalogs:create --server platform-api.myserver.com --org myorg -
Reading CATALOG_FILE arg from stdin
name: production
title: Production Catalog
summary: Catalog containing APIs in production use
```

- Create a new consumer organization:

```
apic consumer-orgs:create --server platform-api.myserver.com --catalog sandbox --org myorg -
Reading CONSUMER_ORG_FILE arg from stdin
name: finance-apps
title: Developers of finance applications
owner_url: https://platform-api.myserver.com/api/user-registries/a1fb8159-fda1-410f-93ab-a0ea5fd04535/70ce7ec3-e83f-4c87-
9f3c-4662ad108bbc/users/fddd5df5-c178-4a34-ab92-0a48344d5c9b
```

  Note: You can obtain the `owner_url` property value by using the following command, which returns the `url` property for a specific user:

```
apic users:get username --user-registry user_registry_name --server mgmt_endpoint_url --org organization_name --fields url
--output -
```

- Register a new developer application:

```
apic apps:create --server consumer-api.myserver.com --org my-consumer-org --mode consumer -
Reading APP_FILE arg from stdin
name: finance
title: Finance application
summary: Mobile app for personal finance management
```

- Create a new email server:

```
apic mail-servers:create --org admin --server platform-api.myserver.com  -
Reading MAIL_SERVER_FILE arg from stdin
title: My email server
name: my-email-server
host: smtp.myemail.com
port: 20
credentials:
  username: me@myemail.com
  password: password
```

- Create a new subscription to subscribe an application to a Product:

```
apic subscriptions:create --app myapp --catalog sandbox --org myorg --server platform-api.myserver.com --consumer-org my-
consumer-org -
Reading SUBSCRIPTION_FILE arg from stdin
product_url: https://platform-api.myserver.com/api/catalogs/960733c1-d7f7-4b90-9bc7-69dbfbe4ce31/ca34537d-adf4-4320-8495-
a7feaa62d679/products/638015c6-a8b0-452e-841f-2ac441ab6962
plan: default-plan
```

  Note: You can obtain the `product_url` property value for a Product by using the following command, which lists the URLs for all versions of a Product given the Product name:

```
apic products:list product_name --scope catalog --catalog catalog_name --org provider_org_name --server mgmt_endpoint_url
```

Scripting with the toolkit commands

The IBM® API Connect developer toolkit provides commands for cloud administration and API development and management.

Scripting commands

It's often helpful to automate a series of **apic** commands In a shell script. Since the **apic** tool first requires you to interactively accept the license, you must first use the following command:

```
apic --accept-license
```

Once you do that, your scripts can run non-interactively.
Toolkit command scripts allow you to automate many of the tasks required to set up and maintain your API products. A set of example scripts are available at **https://github.com/ibm-apiconnect/example-toolkit-scripts**.

These scripts demonstrate how to perform the following tasks.

- Create a Provider Organization
- Configure a catalog to use one or more gateways
- Create draft APIs and Products
- Publish Products
- Replace an existing published product with a new version
- Delete a product
- Create a Consumer Organization
- Create a new consumer app
- Subscribe the new app to an existing published product
- Stage a new product version
- Supercede the existing published product with the new one
- Migrate existing subscriptions from the old product to the new product

Working with OpenAPI extensions

Use the developer toolkit CLI **extensions** commands to manage OpenAPI extensions in your Catalogs or Spaces.

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API, depending on the version of IBM® API Connect you are using. An extension is imported into a Catalog, or as Space ion a Catalog, then added to the API schema.

The commands described here are for importing OpenAPI extensions into a Catalog or Space, and viewing and managing them. After you have imported an OpenAPI extension, you can reference it in your API definitions; for details, see Referring to an extension in an API definition.

Note: If Spaces are enabled in a Catalog, an OpenAPI extension that you import into one Space is imported into **all** Spaces; you cannot import an OpenAPI extension into an individual Space in the Catalog. Any subsequent updates are also applied to all Spaces.

Command name	Action	Syntax

Command name	Action	Syntax
extensions clear	The **extensions:clear** command deletes all versions of an extension given the extension name. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --configured-gateway-service <*service_name*> Specifies the name of the gateway service. --confirm <*catalog_name*> Confirms the clear of the extension. <*extension_name*> Specifies the name of the existing extension. Note: This is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --server or -s <*management_server_endpoint*> Specifies the server endpoint.	**apic extensions:clear** --scope **catalog|space** --catalog_|_-c *catalog_name* *extension_name* --server_|_-s *management_server_endpoint* --configured-gateway-service *gw_service_name* --confirm *catalog_name* --org_|_-o *org_name* **[--space** *space***]** Example: **apic extensions:clear --scope catalog** **--catalog catalog1 extension1 --server endpoint1** **--configured-gateway-service gw_service1** **--confirm catalog1 --org my_org** This example deletes all versions of the **extension1** extension that are in **catalog1** of the **my_org** organization, and are paired with **endpoint1**.
extensions clear-all	The **extensions:clear-all** command deletes all of the extensions in the specified Catalog or Space. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --configured-gateway-service <*service_name*> Specifies the name of the gateway service. --confirm <*catalog_name*> Confirms the clear of the extension. --org or -o <*organization_name*> Specifies a single organization with the organization name. --server or -s <*management_server_endpoint*> Specifies the server endpoint.	**apic extensions:clear-all** --scope **catalog|space** --catalog_|_-c *catalog_name* --server_|_-s *mgt_server_endpoint* --configured-gateway-service *gw_service_name* --confirm *catalog_name* --org_|_-o *org_name* **[--space** *space***]** Example: **apic extensions:clear-all --scope catalog** **--catalog catalog1 --server endpoint1** **--configured-gateway-service gw_service1** **--confirm catalog1 --org my_org** This example deletes all the extensions that are in **catalog1** of the **my_org** organization, and are paired with **endpoint1**.

Command name	Action	Syntax
extensions clone	The **extensions:clone** command creates a local definition file for each extension. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope** **space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:clone --scope catalog|space** **--catalog | -c *catalog_name*** **--org | -o *org_name*** **[--space *space*]** **--server | -s *mgt_server_endpoint*** **--configured-gateway-service *gw_service_name*** Example: **apic extensions:clone --scope catalog** **--catalog catalog1 --org my_org --server endpoint1** **--configured-gateway-service gw_service_1** This example clones the extensions that are in **catalog1** of the **my_org** organization, and are paired with **endpoint1**.
extensions create	The **extensions:create** command creates an extension in a Catalog or Space, given an extension definition file. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. <*extension_file*> Specifies the name of the extension file that contains the new information for your extension. Note: This is the OpenAPI file name, not the name of the extension. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope** **space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:create --scope catalog|space** ***extension_file*** **--server | -s *mgt_server_endpoint*** **--catalog | -c *catalog_name*** **[--space *space*]** **--org | -o *org_name*** **--configured-gateway-service *gw_service_name*** Example: **apic extensions:create --scope catalog filename.yaml** **--server endpoint1 --catalog catalog1 --org my_org** **--configured-gateway-service gw_service_1** This example creates an extension in **catalog1** of the **my_org** organization, paired with **endpoint1**, using the **filename.yaml** OpenAPI extension definition file.

Command name	Action	Syntax
extensions delete	The **extensions:delete** command deletes a specific version of an extension. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope** **space** in the command. <*extension_name*>:<*version_number*> Specifies the name and version number of the extension. Note: *extension_name* is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:delete** **--scope** **catalog|space** ***extension_name*:*version_number*** **--catalog | -c** ***catalog_name*** **--org | -o** ***org_name*** **[--space** ***space*]** **--server | -s** ***mgt_server_endpoint*** **--configured-gateway-service** ***gw_service_name*** Example: **apic extensions:delete --scope catalog myextension:1.0.0 --catalog catalog1 --org orgmain --server endpoint1 --configured-gateway-service gw_service_1** This example deletes **myextension** version **1.0.0** that is in **catalog1** of the **orgmain** organization, and is paired with **endpoint1**.
extensions get	The **extensions:get** command retrieves the definition file for a specific version of an extension. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope** **space** in the command. <*extension_name*>:<*version_number*> Specifies the name and version number of the extension. Note: *extension_name* is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:get** **--scope** **catalog|space** ***extension_name*:*version_number*** **--catalog | -c** ***catalog_name*** **--org | -o** ***org_name*** **[--space** ***space*]** **--server | -s** ***mgt_server_endpoint*** **--configured-gateway-service** ***gw_service_name*** Example: **apic extensions:get --scope catalog myextension:1.0.0 --catalog catalog1 --org orgmain --server endpoint1 --configured-gateway-service gw_service_1** This example gets **myextension** version **1.0.0** that is in **catalog1** of the **orgmain** organization, and is paired with **endpoint1**.

Command name	Action	Syntax
extensions list	The **extensions:list** command lists all versions of an extension given the extension name. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. <*extension_name*> Specifies the name of the existing extension. Note: This is the extension name, not the file name. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:list** [**--scope** **catalog|space**] *extension_name* [**--catalog**	**-c** *catalog_name*] [**--org**	**-o** *org_name*] [**--space** *space*] [**--server**	**-s** *mgt_server_endpoint*] [**--configured-gateway-service** *gw_service_name*] Example: **apic extensions:list --scope catalog my_extension --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service_1** This example lists all versions of the extension **my_extension** that are paired with **endpoint1**, are in **catalog1**, and in the **my_org** organization.
extensions list-all	The **extensions:list-all** command lists all of the extensions that are available in a Catalog or Space. This is the default command if you enter only **apic extensions**. The parameters are as follows: --scope Specifies whether you want to clone the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **org** Sets the scope to the organization. **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service.	**apic extensions:list-all** [**--scope** **catalog|space**] [**--catalog**	**-c** *catalog_name*] [**--org**	**-o** *org_name*] [**--space** *space*] [**--server**	**-s** *mgt_server_endpoint*] [**--configured-gateway-service** *gw_service_name*] Example: **apic extensions:list-all --scope catalog --catalog catalog1 --org my_org --server endpoint1 --configured-gateway-service gw_service1** This example lists the extensions that are paired with **endpoint1**, are in **catalog1**, and in the **my_org** organization.

Command name	Action	Syntax
extensions update	The **extensions:update** command replaces the information of an existing version of an extension with the information in an external file. The parameters are as follows: --scope Specifies whether you want to clear the extensions in a Catalog or Space. The following options are available: **catalog** The command is to be applied to Catalog **space** The command is to be applied to a Space in a Catalog. When Spaces are enabled in a Catalog, you must set the scope to **space** and supply the **--space** parameter. --server or -s <*management_server_endpoint*> Specifies the server endpoint. --catalog or -c <*catalog_name*> Specifies a single Catalog with the Catalog name. --space Specifies the name of a Space in a Catalog. The **--space** parameter is required if the Catalog has Spaces enabled, in which case you must also include **--scope space** in the command. --org or -o <*organization_name*> Specifies a single organization with the organization name. --configured-gateway-service <*service_name*> Specifies the name of the gateway service. <*extension_name*>:<*version_number*> Specifies the name and version number of the extension. Note: *extension_name* is the extension name, not the file name. <*extension_file*> Specifies the name of the extension file that contains the new information for your extension. Note: This is the OpenAPI file name, not the name of the extension.	**apic extensions:update** **--scope** **catalog|space** ***extension_name*:*version_number*** ***extension_file*** **--catalog | -c** ***catalog_name*** **--org | -o** ***org_name*** **[--space** ***space*]** **--server | -s** ***mgt_server_endpoint*** **--configured-gateway-service** ***gw_service_name*** Example: **apic extensions:update** **--scope catalog extension1:1.0.0 extension2.yaml** **--catalog catalog1 --org my_org --server endpoint1** **--configured-gateway-service gw_service1** This example updates **extension1** version **1.0.0** that is paired with **endpoint1**, in **catalog1**, and in the **my_org** organization, from the file **extension2.yaml**.

Using the toolkit CLI to execute API tests

The IBM® API Connect developer toolkit provides CLI commands for automated API behavior testing.

About this task

Use CLI commands to execute API tests.
Note: In order to execute an API for testing purpose, you must make it online. To make the API online and auto-publish your API document, set the **Auto-publish** toggle on the Preferences page to **On** position. For more information, see Activating an API.

Procedure

1. Install the toolkit: Setting up the API Connect toolkit.
2. Open Terminal.
3. Create a YAML file to define your tests. For more information, see API development and management commands.
4. Run the CLI with the following syntax to execute the tests:

   apic test ***yaml-files***

   Where, ***yaml-files*** specifies the location of the YAML file. For example, **apic test test1.yaml**
   - For executing tests with certificate checks disabled, run the CLI using the **--insecureSkipVerify** flag. For this, use the following syntax:

     apic test ***yaml-files***
     --insecureSkipVerify

     Where, ***yaml-files*** is the location of the YAML file. For example, **apic test test1.yaml**.
   - If the CA certificate is not available in the system's keystore, its location can be specified with **--certPath** flag. For this, run the CLI with the following syntax:

     apic test ***yaml-files***
     --certPath=*location of certs folder*

     Where, ***yaml-files*** is the location of the YAML file. For example, **apic test test1.yaml**. ***location of certs folder*** specifies the location of the CA certificate.
   - For executing tests with mTLS enabled, run the CLI using the **--mtls** flag. For this, use the following syntax:

     api-test test ***yaml-files***
     --mTLS --certPath=*location of certs folder*

     Where, ***yaml-files*** is the location of the YAML file. For example, **apic test test1.yaml**.

- For passing external configuration, run the CLI using the `--config-file` flag. For this, use the following syntax:

  ```
  api-test test yaml-files
    --config-file=location of config file
  ```

  Where, ***yaml-files*** is the location of the YAML file. For example, **apic test test1.yaml**. ***location of config file*** specifies the location of the configuration file.

Note: Cert files must be named in the following format:

- **tls.crt** - public key
- **tls.key**- private key
- **ca.crt**- CA certificate

For more information about how the test is defined as a YAML file, see Test definition syntax.
For more information about the assigning variables on a YAML configuration file, see Variable assignment in YAML configuration.

- **Test definition syntax**
  Information about how the test is defined as a YAML file.
- **Variable assignment in YAML configuration**
  You can define variables within a YAML configuration file using the CLI tool. These variables are used to configure various aspects of the tool.

Test definition syntax

Information about how the test is defined as a YAML file.

The test is defined as a YAML file with the following sections:

- **configs** - Displays the configuration values for the variables that are specified in the file.
- **steps** - Displays the flow for the test case and runs through the list of steps in order. Each step has a common set of parameters.

The **type** attribute in the test definition YAML file describes the type of **steps**.

```
requirements: {}

info:
  title: "New Configuration YAML File"
  version: 2

configs:
  globalVariables:
    protocol: https://
    domain: sample-api.us-east-a.apiconnect.automation.ibm.com
    basePath: /bank

  inputs:
    - default:
        value: string
        type: array
    - second:
        value: number
        type: string

  steps:
    - type: request
      method: get
      url: "{{ configs.globalVariables.protocol }}{{ domain }}{{ globalVariables.basePath }}/branches"
      var: branches
      mode: json

    - type: assert-is
      expression: branches
      value: "{{ type }}"

    - type: assert-exists
      expression: branches.[1]
      stoponfail: true

    - type: assert-is
      expression: branches.[0].type
      value: string
      stoponfail: true

    - type: assert-is
      expression: branches.[0].address.city
      value: string
      stoponfail: true

    - type: assert-compares
      expression1: branches.[0].type
      expression2: branches.[7].type

    - type: request
      method: get
      url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/orders/order/AB1234
      var: payload
      mode: json

    - type: assert-equals
      expression: payload_response_statusCode
      value: 200
      ifexists: false
```

```
    stoponfail: false

  - type: assert-equals
    expression: payload_response_header_Content-Type
    value: application/json

  - type: assert-in
    expression: payload_response_header_Content-Type
    values:
      - application/json
      - application/swagger+yaml

  - type: assert-contains
    expression: payload_response_header_Content-Type
    value: app

  - type: assert-matches
    expression: payload_response_header_Content-Type
    value: ^[a-z]+/json

  - type: assert-exists
    expression: "payload"
    stoponfail: false

  - type: assert-is
    expression: "payload.tracking_reference"
    value: "string"
    ifexists: "false"
    stoponfail: false

  - type: assert-exists
    expression: payload.shipped_at
    stoponfail: false

  - type: assert-exists
    expression: payload.status
    stoponfail: false

  - type: assert-exists
    expression: payload.created_at
    stoponfail: false
```

The following table summarizes the set of parameters supported by the **type** attribute.

Table 1. Summary of the parameters supported by the **type** attribute

Parameters	Description	Sub-attributes
globalVariables	Global variables are settings that remain consistent across the entire test and typically do not change between runs.	You can define any attributes here based on your requirements. For example: • **https://** - Used in all requests, ensuring secure communication • **domain**: Specifies the primary server address for API requests • **basepath**: Defines the base path for all API endpoints. For example, **/bank**), which is appended to the domain for constructing request URLs
inputs	Defines various sets of input parameters used across multiple test scenarios.	You can create multiple data sets with any attributes needed for specific test scenarios. For example, **default** and **second** are two data sets, each with its own attributes tailored for different scenarios. **Note:** At least one data set must be present to run the test.

request	Make an HTTP request.	• **method** - defines the HTTP method to use.
		• **url** - defines the URL to make the request to.
		• **params** - defines the key value mapping of parameters to send.
		• **headers** - defines the key value mapping of headers to send.
		• **var** - defines the name of the variable to store the response in.
		• **mode** - defines what type of data to expect and how to parse it (supported: json).
		• **insecureSkipVerify** - Use this attribute and set the value to `true` while using custom certificates.
		
		For example,
		
		`- type: request`
		`method: get`
		`url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/bank/branches`
		`var: branches`
		`mode: json`

assert-is	Assert that the type of variable from the response is **value**.	• **expression** - defines the variable to test.
		• **value** - defines the **type** we expect in response.
		
		For example,
		
		`- type: assert-is`
		`expression: branches`
		`value: array`

Parameters	Description	Sub-attributes

`assert-exists`	Assert that a particular variable specified in `expression` exists.	• `expression` - defines the variable to test.
		• `stoponfail` - If one of the test fails, the `stoponfail`attribute stops the execution of the remaining tests. For this, `stoponfail` must be set to `true`.
		
		For example,
		
		`- type: assert-exists`
		`expression: branches.[1]`
		`stoponfail: true`

`assert-equals`	Assert that a variable is equal to `value`.	• `expression` - defines the variable to test.
		• `value` - defines the `value` to compare against .
		
		For example,
		
		`- type: assert-equals`
		`expression: payload_response_header_Content-Type`
		`value: application/json`

`assert-greater`	Assert that the variable is greater than `value`.	• `expression` - defines the variable to test.
		• `value` - defines the `value` to compare against.
		
		For example,
		
		`- type: assert-greater`
		`expression: payload_temperature`
		`value: application/json`

`assert-less`	Assert that the variable is lesser than `value`.	• `expression` - defines the variable to test.
		• `value` - defines the `value` to compare against.
		
		For example,
		
		`- type: assert-less`
		`expression: payload_temperature`
		`value: application/json`

`assert-in`	Assert that the element identified by a given expression matches at least one item from a given list.	• `expression` - defines the variable to test.
		• `value` - defines an array of values to compare against.
		
		For example,
		
		`- type: assert-in`
		`expression: payload_response_status`
		`value: application/json`

`assert-matches`	Assert that the value of the element identified by a given expression matches a specified format.	• `expression` - defines the variable to test.
		• `value` - defines the regex value to compare against.
		
		For example,
		
		`- type: assert-matches`
		`expression: payload_response_header_Content-Type`
		`value: ^[a-z]+/json`

`assert-compares`	Assert that two elements are equivalent in some way.	• `expression1` - defines the path to the first element for comparison.
		• `expression2` - defines the path to the second element for comparison.
		
		For example,
		
		`- type: assert-compares`
		`expression1: branches.[0].type`
		`expression2: branches.[7].type`

`assert-contains`	Assert that the value of the element identified by a given expression contains a specific substring.	• `expression` - defines the variable to test.
		• `value` - defines the substring to compare against.
		
		For example,
		
		`- type: assert-contains`
		`expression: payload_response_header_Content-Type`
		`value: app`

`each`	Loop over the array referenced in the expression carrying out the sub-steps for each item found.	`expression` - defines the variable to test.
		
		For example,
		
		`- type: each`
		`expression: "analytics.events"`

For more information about assigning variables on a YAML configuration file, see Variable assignment in YAML configuration.

Variable assignment in YAML configuration

You can define variables within a YAML configuration file using the CLI tool. These variables are used to configure various aspects of the tool.

You can configure a YAML file in three ways:

- Using the same YAML file.
- Using environmental variables
- Using the external configuration YAML files.

Note: Variables must be enclosed in double curly braces. For example, `"{{configs.base_url}}"` or `"{{paths.basePath}}"`. These placeholders, in the format of `"{{...}}"`, will be replaced with their corresponding values from the source YAML file, environmental variables, or the external configuration file depending on the precedence hierarchy.
The precedence hierarchy for variable assignment is as follows:

1. External configuration YAML file (highest precedence)
2. Environmental variables
3. Configuration set in the same YAML file (lowest precedence)

If you configure a YAML file using all the three methods, the variables assigned using the external configuration YAML file is given priority.

1. Configuration set in the same YAML file

You can assign values to variables from within the same YAML file. For this, you must structure your YAML file in the following manner:

```
configs:
   basePath: ...paths:
       - basePath: ...
```

Here, the **configs** key is used to define variables such as **basePath** and **paths**. These variables can be utilized throughout the YAML file to configure the tool.

2. Environmental variables

You can override the values of variables configured in the YAML file using environmental variables. When an environment variable shares the same name as a variable defined in the YAML file, the value of the YAML variable is replaced by the corresponding environment variable. This provides a way to customize configurations externally.

For example, if a variable named **base_url** is defined in the YAML file as **"{{configs.base_url}}"**, and its value is replaced by an environment variable named **base_url**. The value of **base_url** in the YAML file is overridden by the value of the **base_url** environment variable.

3. External configuration YAML file

The CLI tool supports the highest level of configuration precedence through external configuration files. To use an external configuration file, you must specify its file path using the **--config-file** or **-c** flag when running the CLI tool. Any variables defined in the external configuration file will supersede those defined within the main YAML file or through the environmental variables.

For example, consider an external configuration file named **config.yaml** with the following content:

```
external_config:
   base_url: https://example.comapi_key: your-api-key
```

When you run the CLI tool with the **--config-file=config.yaml** flag, variables defined in the**config.yaml** file will replace the corresponding variables in the main YAML file or the environmental variables.

For more information about how the test is defined as a YAML file, see Test definition syntax.

Managing platform REST API keys

Create API keys associated with your user account, and then use them to authenticate when you call the platform REST APIs provided by API Connect.

About this task

The API Connect platform REST APIs require authentication for use. To call an API interactively, you can log into the toolkit CLI with an option to generate the API key. To call an API programmatically, you can generate an API key and then exchange it for an API Connect access token. This requirement applies only to the APIs that are provided by API Connect. You do not need the API key for calling APIs that you imported or created. The API key is intended for use with the OIDC user registry type. Remember: By default, API keys are configured to be used onlyonce. However, you can customize the configuration and modify the API lifespan by following thesteps provided in the Configuring API key settingstopic.

Procedure

1. Create an API key:
   a. Log in to API Connect.
   b. On the address bar, add **/apikeys** to the end of the URL (after the organization name).
      For example:

      ```
      https://manager.example.com/manager/myorg/apikeys
      ```

   c. On the API Keys page, click Add.
   d. In the "Create API Connect API Key" box, provide a title for the key (unique within your user account) and a description; then click Create.
      The button is disabled until you provide a description.

2. Manage API Keys:
   a. Log in to API Connect.
   b. On the address bar, add **/apikeys** to the end of the URL.

Searching for items in API Manager

Use the search feature in IBM® API Connect API Manager to easily locate items such as APIs, Catalogs, Spaces, applications, and subscriptions.

Search is available from any page in API Manager and can be accessed by typing in the search field in the page banner, or by clicking Search in the navigation list.

Using Search

The Search feature is available on all pages of the API Manager. To start searching, just type a string into the Search field and press Enter. Whenever you press Enter in the Search field, the Search page displays with results and additional options. If you press Enter in an empty Search field, or click Search in the navigation list, then the Search page displays a list all items. If you type a string before pressing Enter, the page displays the results from the corresponding search.

Search results include all items that contain the search string in a text field. For example, suppose you searched for "Crafted". The results might look like the following image, with items that don't match the search string exactly, but do include the string in a text field such as a title or a name.

By default, the search returns all types of items that contain the string. Sort results on a particular column by clicking the column header.

When you find an item you want to work with, click the . . . actions menu next to the item's "Modified" date to see what you can do. The list of possible actions depends on the item's type.

You can limit the search results by selecting an item type from the list that displays before the results. Click More to view additional types. If you select a type from the More menu, it replaces a type in the list.

If you want to refine the search further, click Options. On the Options panel, click Catalogs to Search and select which catalogs to search (the default is all catalogs). You can select up to 5 catalogs for a limited search.

You can also choose whether only exact matches (the complete string) are included in results, or items containing similar strings are also included.

Working with API definitions

An API definition specifies the complete configuration for an API. You can create and configure your APIs either by using either the API Designer UI application, or by using the browser based API Manager UI.

Note: In the Help page of the Cloud Manager, API Manager, and API Designer user interfaces, there's a Product information tile that you can click to find out information about your product versions, as well as Git information about the package versions being used. Note that the API Designer product information is based on its associated management server, but the Git information is based on where it was downloaded from.
If you are working with APIs that conform to the OpenAPI Specification, note that API Connect uses the following terms:

- OpenAPI Specification:
  The OpenAPI Specification defines a standard, language-agnostic interface to RESTful APIs. API Connect supports version 2.0 and version 3.0 of the OpenAPI Specification.
- OpenAPI document:
  One or more files that describe an API conforming to the OpenAPI Specification.
- OpenAPI definition:
  The description of an API that conforms to the OpenAPI Specification. In API Connect, you can create the API definition by filling in settings and properties, or by importing an OpenAPI document that contains an API definition that you want to work with.

The following topics provide full details for creating and configuring your APIs.

- **Using the AI Gateway to support APIs for AI applications**
  API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with AI services to forward requests and manage responses.
- **Creating an API definition**
  You can create API definitions by using the API Designer or the command line interface in IBM® API Connect.
- **Editing an OpenAPI 2.0 API definition**
  IBM API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 2.0 specification.
- **Editing an OpenAPI 3.0 API definition**
  IBM API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 3.0 specification.
- **LDAP authentication**
  The Lightweight Directory Access Protocol (LDAP) is an internet protocol for accessing and maintaining distributed directory information services over a network. If you rely on LDAP to authenticate users for web applications, take a minute to review the contents of this topic before beginning.
- **Authentication URL user registry**
  You can use an Authentication URL user registry to specify a REST authentication service to manage user authentication, and to optionally provide additional metadata to be embedded in the token.
- **Activating an API**
  After you have created an API definition you can activate it to auto-publish your API document and make it available for testing.
- **Testing an API**
  Select a test tool and verify that your API works as you intended.
- **Staging an API**
  The graphical wizard provides an option that adds the API to a Product and stages the Product in a Catalog. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.
- **Publishing an API**
  The user interface provides an option that adds an API to a Product and publishes the Product in a Catalog. Publishing a draft Product makes the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.
- **Creating a new version of an API definition**
  You can create multiple versions of an API definition and edit the versions independently by using IBM API Connect.

- **Updating an API definition from a file**
  You can update an API by uploading a .yaml or .json file that contains the OpenAPI definition for the revised API.
- **Updating a SOAP API**
  You can update the configuration of an existing SOAP API either by uploading a WSDL file, or by uploading a .zip archive that contains a primary WSDL file together with other WSDL or XSD files that it references.
- **Renaming an API definition**
  By renaming an API definition, you change the `name` property that, together with the version, is used to uniquely identify the API definition in API Connect. The `name` property is initially generated automatically when you first create the API definition, based on the title, but you can later change it if desired.
- **Changing an API rate limit**
  When you activate an API to make it available for testing, as described in Activating an API, no rate limit is applied to restrict calls to the API. However, if desired, you can apply a rate limit to the API, or modify a previously applied rate limit. The rate limit defines the maximum number of calls allowed in a specified time period.
- **Adding an OpenAPI extension to an API**
  You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An OpenAPI extension is imported into a Catalog, or to a Space within a Catalog, then added to the API schema.
- **Downloading an API definition**
  You can download the details of your API definitions so that you can store them for later recovery.
- **Deleting an API definition**
  You can delete an API definition that is no longer required.
- **Using an options file when importing a WSDL service**
  When you create an API definition, or add a target WSDL service to an API definition, by importing a .zip file, you can specify additional directives by including an options file in the .zip file.
- **Variable references in API Connect**
  In API Connect you can reference different variables in your API definition.
- **API properties**
  Properties are used by the gateway to control behavior of certain policies. Typically, you provide properties, but the policy can also provide properties settings.
- **API policies and logic constructs**
  Policies and logic constructs are pieces of configuration that control a specific aspect of processing in the Gateway server during the handling of an API invocation at run time.
- **Tags in API Connect**
  There are a number of forms of tagging in IBM API Connect.

Using the AI Gateway to support APIs for AI applications

API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with AI services to forward requests and manage responses.

AI Gateway functionality allows you to access AI Gateway policies directly on the DataPower API Gateway. You can create REST proxies that use the AI Gateway to control access to AI models, providing a seamless way to manage AI access within your API infrastructure while ensuring enhanced security and governance of your AI models.

The AI Gateway makes it easy for enterprises to manage access to API endpoints used by AI applications. The AI Gateway simplifies the integration of AI into new and existing OpenAPI 3.0 APIs in API Connect to access a set of operations exposed by an AI service.

Note: The AI Gateway is not a separate gateway service; it is enabled by default while registering the DataPower® API Gateway. AI Gateway uses API assembly policies provided by the DataPower API Gateway service, and provides a single point of control for organizations to access AI services through APIs.

Use cases

There are two cases where you should use the AI Gateway:

- As a reverse proxy for an existing API
  In this case, the API contract with the AI service is unchanged.
- As a development tool for new APIs that use an AI service.
  You can create APIs directly in API Connect and define policies in the API workflow to manage access to AI service.

Benefits

With the API Connect AI Gateway, you can centrally manage the use of AI through policy enforcement, data encryption, masking of sensitive data, access control, audit trails and more, in support of your compliance obligations.

Using the AI Gateway to manage your API access to AI service lets you add controls to the API execution through the following features:

- An interface to each supported AI service
  API Connect provides a policy that enables your API to send requests to a specified AI service.
- Response caching
  The response to an API call to an AI service is cached, which improves response time for API calls and provides cost optimization for the API provider. When you create an API in API Connect, you can specify the duration for that API's response caching.
- Rate limiting
  The AI Gateway enforces defined rate limits on APIs and API Plans (which manage access to individual APIs). You can configure rate limits based on the number of requests or generated tokens allowed within a particular time interval.
- Tokenization
  Tokens are used as a unit of cost for LLM APIs. With the AI Gateway, rate limits can use the number of tokens generated by a request as a means of limiting usage and thus controlling costs. The token limit determines how many tokens are allowed to pass thru the gateway within a specified period of time.
- Predefined policies and logic structures
  The AI Gateway can leverage all of the existing policies and logic constructs provided by API Connect (for example, invoke, redact, and validate) in the API execution flow.
- API analytics

API Connect provides an analytics service that provides insights into AI Gateway usage. You can use the analytics data on the AI usage dashboard to manage costs and track performance. For more information, see Accessing analytics in the API Manager UI.

The AI Gateway supports the following AI services:

- **Using the AI Gateway to support watsonx.ai APIs**
  The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with watsonx.ai to forward requests and manage responses.
- **Using the AI Gateway to support OpenAI APIs**
  The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with OpenAI to forward requests and manage responses.
- **Using the AI Gateway to support Gemini APIs**
  The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with Gemini to forward requests and manage responses.

Using the AI Gateway to support watsonx.ai APIs

The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with watsonx.ai to forward requests and manage responses.

The AI Gateway makes it easy for enterprises to manage access to API endpoints used by AI applications. The AI Gateway simplifies the integration of AI into new and existing OpenAPI 3.0 APIs in API Connect to access a set of operations exposed by watsonx.ai.

API Connect provides a policy that enables your API to send requests to watsonx.ai. The following watsonx.ai specs are supported:

- `/text-generate`
- `/tokenize`
- `/deployment-models`

Prerequisites for using the AI Gateway with watsonx.ai

Before attempting to use the AI Gateway, complete the following prerequisites:

- Obtain an IBM Cloud API key.
  When you register for an IBM Cloud ID, an API key is automatically assigned. You can create additional API keys if needed. An API key is used by the IBM Cloud Authentication user defined policy to generate a Bearer token, which is used to authenticate for the desired watsonx.ai service. For information on managing API key, see Understanding API keys in the IBM Cloud documentation.
- Create a watsonx.ai project.
  A watsonx.ai project is required for the user that is identified by the API key. The project will have a project ID. For information on creating projects, see Creating a project in the watsonx.ai documentation.
- Link the watsonx.ai project to an LLM service by completing the following steps:
  1. In the project, click Services and Integrations in the navigation list.
  2. Create a service; for example, you might call it "Watson Machine Learning".
  3. Associate that service with your project.

  Failure to configure your project correctly will result in a `400 Bad Request` response for attempted watsonx.ai operations.

Getting started with the AI Gateway and watsonx.ai

To use the AI Gateway with watsonx.ai, complete the following steps:

1. Set up your environment as explained in Using the AI Gateway to support watsonx.ai APIs.
2. Create an API to use as a reverse-proxy.
3. Add the IBM Cloud Authentication and watsonx.ai invoke policies to the API so it can authenticate with IBM Cloud and access watsonx.ai.
4. Review metrics on the API's performance in the AI usage dashboard, which tracks AI token and model usage.

Using the AI Gateway to support OpenAI APIs

The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with OpenAI to forward requests and manage responses.

The AI Gateway makes it easy for enterprises to manage access to API endpoints used by AI applications. The AI Gateway simplifies the integration of AI into new and existing OpenAPI 3.0 APIs in API Connect to access a set of operations exposed by OpenAI.

API Connect provides a policy that enables your API to send requests to OpenAI. The following OpenAI operations are supported:

- `POST /chat/completions`
- `POST /embeddings`
- `GET /models`
- `GET /models/[model-id]`

Prerequisites for using the AI Gateway with OpenAI

Before attempting to use the AI Gateway with OpenAI, complete the following prerequisites:

- Register with OpenAI.

Note: When you register your OpenAI id, a default project is created for you. You can use this project or create additional projects. OpenAI projects will allow customers to organize their work within the OpenAI platform. From the AI Gateway perspective, the OpenAI project id is an optional property that will associate an OpenAI request to a specific project.
- Obtain an OpenAI API key.

Getting started with the AI Gateway and OpenAI

To use the AI Gateway, complete the following steps:

1. Set up your environment as explained in Prerequisites for using the AI Gateway with OpenAI.
2. Create an API to use as a reverse-proxy.
3. Add the OpenAI invoke policy to the API so it can access the OpenAI platform.
4. Review metrics on the API's performance in the AI usage dashboard, which tracks AI token and model usage.

Using the AI Gateway to support Gemini APIs

The API Connect provides a UI wizard to create AI-aware APIs and products, plus integration with Gemini to forward requests and manage responses.

The AI Gateway makes it easy for enterprises to manage access to API endpoints used by AI applications. The AI Gateway simplifies the integration of AI into new and existing OpenAPI 3.0 APIs in API Connect to access a set of operations exposed by Gemini.

API Connect provides a policy that enables your API to send requests to Gemini. The following Gemini operations are supported:

- `GET /models`
- `GET /models/[model]`
- `POST /models/[model]:generateContent`
- `POST /models/[model]:countTokens`
- `POST /models/[model]:embedContent`
- `POST /models/[model]:batchEmbedContents`

Prerequisites for using the AI Gateway with Gemini

Before attempting to use the AI Gateway with Gemini complete the following prerequisites:

- Register with Google Studio.
  Note: When you register with Google Studio, a default project is created for you. You can use this project or create additional projects.
- Navigate to the API Key Management Page to create an API key. You can also manage projects and API keys in Google Cloud by following the links provided on the API Key Management Page.

Getting started with the AI Gateway and Gemini

To use the AI Gateway, complete the following steps:

1. Set up your environment as explained in Prerequisites for using the AI Gateway with Gemini.
2. Create an API to use as a reverse-proxy.
3. Add the Gemini invoke policy to the API so it can access the Gemini platform.
4. Review metrics on the API's performance in the AI usage dashboard, which tracks AI token and model usage.

Creating an API definition

You can create API definitions by using the API Designer or the command line interface in IBM® API Connect.

Before you begin

An API is a set of functions that provide some business or technical capability and can be called by applications by using a defined protocol. Applications are typically mobile or web applications, and they use the HTTP protocol. An API definition is composed of paths, and can be one of the following types:

REST API definition
: A REST API is a defined set of interactions that uses the HTTP protocol, typically by using JSON or XML as the data format that is exchanged. For example, a data request might use an HTTP GET method, and a data record might use an HTTP POST method. The choice of data format depends on the type of application that is calling the API. JSON is commonly used for web pages or mobile applications that present a user interface (by using JavaScript or HTML), whereas XML is often used for machine-to-machine scenarios.

  You can expose and secure your existing APIs by using a Proxy or Invoke policy.

  In either case, you can configure your API definition either by using the API Designer, or by writing an OpenAPI definition file and publishing it using either API Designer or the command line interface.

SOAP API

You can create SOAP API definitions that are based on an existing Web Services Description Language (WSDL) file. You can use this facility to benefit from the capabilities that are provided by API Connect, which include analytics and mapping between variables. You can also expose the API by using the Developer Portal for any existing SOAP services in your organization, including any SOAP services that are part of a service-oriented architecture (SOA) or Enterprise Service Bus (ESB) infrastructure.

You can create SOAP API definitions through either the command line interface, or through API Designer.

About this task

You can create definitions for REST APIs or SOAP APIs.

- In the API Designer, you can add a REST API definition either by composing the API definition, and its operations, from scratch, or by importing an OpenAPI definition file. You can also use the tooling to quickly create a proxy API that calls an existing endpoint.
- If you have an existing SOAP service that you want to expose more widely, you can add a SOAP API to IBM® API Connect. You can use the Developer Portal to publicize the SOAP service to the developers. If a developer wants to use the SOAP API, you can use API Connect to manage their sign-up and access to the service, and track the usage of that API.

Procedure

1. Quickly create an API definition by using one of the following wizards:
   - Creating a REST proxy API from a target service
   - Creating a REST proxy API from an existing OpenAPI service
   - Creating a new REST OpenAPI definition
   - Creating a REST proxy API from an existing WSDL service
   - Adding a REST API by importing an OpenAPI definition file
   - Creating a SOAP proxy API from an existing WSDL service
2. After you create your API definition, you can define it in more detail by following the instructions in Editing an OpenAPI 2.0 API definition.

- **Creating a REST proxy API from a target service**
  If you have an existing REST service that you want to expose through an IBM API Connect API definition, you can create a proxy API and specify the target endpoint by using the API Designer.
- **Creating a REST proxy API from an existing OpenAPI service**
  If you have an existing OpenAPI described target service that you want to expose through an IBM API Connect API definition, you can create a proxy API and specify the target endpoint.
- **Creating a REST proxy API from an existing WSDL service**
  If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect REST proxy API that calls that SOAP service.
- **Creating a SOAP proxy API from an existing WSDL service**
  If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect SOAP proxy API that calls that SOAP service.
- **Creating a new REST OpenAPI definition**
  You can create and edit draft REST API definitions by using the API Designer or the API Designer user interface in IBM API Connect.
- **Adding a REST API by importing an OpenAPI definition file**
  You can use an OpenAPI definition file to import a REST API into IBM API Connect.
- **Adding a SOAP API by importing a zip file**
  You can use an OpenAPI definition file to import a SOAP API into IBM API Connect.
- **Creating a GraphQL proxy API**
  GraphQL is a query language for APIs that gives an application client greater control over what data it retrieves in an API request when compared with a REST API request. IBM API Connect enables you to create a GraphQL API proxy definition that proxies a backend GraphQL server, and to define rate limiting controls that reflect the amount of data that is returned from the server by a request to the GraphQL API.
- **Importing an API from the CP4I asset repository**
  If you are using API Connect with IBM Cloud Pak for Integration, you can import an API definition from the CP4I asset repository.
- **Importing an AsyncAPI from Event Endpoint Management**
  Import one or more AsyncAPI specifications from Event Endpoint Management.
- **Creating an AsyncAPI with Event Endpoint Management**
  Create an AsyncAPI using Event Endpoint Management.
- **Creating a REST proxy for watsonx.ai with the AI Gateway**
  Create a REST proxy that uses the AI Gateway to control access to AI models.
- **Creating a REST proxy for OpenAI with the AI Gateway**
  Create a REST proxy that uses the AI Gateway to control access to AI models.
- **Creating a REST proxy for Gemini with the AI Gateway**
  Create a REST proxy that uses the AI Gateway to control access to AI models.

- Using the developer toolkit command-line tool

Creating a REST proxy API from a target service

If you have an existing REST service that you want to expose through an IBM® API Connect API definition, you can create a proxy API and specify the target endpoint by using the API Designer.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Create proxy REST APIs in minutes by using the API Designer tool to create an API from target service. This procedure creates a REST proxy that routes all traffic to a target REST API or service endpoint.

Procedure

To compose a proxy API from a target service, complete the following steps.

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select From target service.
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **info.version** property of the API's OpenAPI definition. The **version.release.modification** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
5. Specify the existing REST API endpoint that you want to call in the Target Service URL field.
6. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **X-IBM-Client-Id** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **cors** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **cors** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **request.attributes.isCORSPreflight** flag is set to **true**.
     - For all preflight requests, the **security** and **client-identification** preflow policies are always skipped, whether CORS is enabled or not enabled.
7. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
8. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a proxy API from an existing target service.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Creating a REST proxy API from an existing OpenAPI service

If you have an existing OpenAPI described target service that you want to expose through an IBM® API Connect API definition, you can create a proxy API and specify the target endpoint.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Create proxy REST APIs in minutes by using the API Designer tool to create an API from existing OpenAPI service. This procedure creates a REST proxy that routes all traffic to a target REST API or service endpoint.

Procedure

To compose a proxy API from an existing OpenAPI service, complete the following steps.

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select From existing OpenAPI service, and click Next.
4. To upload the service information from an OpenAPI file, you can either drag and drop your file, or browse and select the file that you want to use. Valid file types are YAML, YML, etc.
   - Click Browse and browse for the OpenAPI file.
   - Drag and drop the file into the active area.

   After you upload the file, the OpenAPI specification is evaluated and a message displays whether it is valid.
5. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **info.version** property of the API's OpenAPI definition. The **version.release.modification** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
6. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **X-IBM-Client-Id** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **cors** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **cors** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **request.attributes.isCORSPreflight** flag is set to **true**.
     - For all preflight requests, the **security** and **client-identification** preflow policies are always skipped, whether CORS is enabled or not enabled.
7. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **Product:Manage** and **Subscription:Manage** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
8. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

   If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

9. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a proxy API from an existing OpenAPI service.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Creating a REST proxy API from an existing WSDL service

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect REST proxy API that calls that SOAP service.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **Api-Drafts:Edit**, **Settings:View**, and **App:View** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

If the WSDL file is a stand-alone file with no external dependencies, you can load the .wsdl file from a directory to create the REST API definition.

If the WSDL file references other WSDL files or references XSD files containing XML schema definitions, you must create a .zip archive of the WSDL file and its dependent documents, and then load the .zip file from a directory to add the REST API definition.

Procedure

To add a REST API definition by loading a WSDL file, complete the following steps:

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. On the Add API pane, select From existing WSDL service (REST Proxy). Click Next.
   The Create API from Existing WSDL Service (REST Proxy) window opens.
4. To upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, you can either drag and drop your file, or browse and select the file that you want to use.
   After you upload the file, the WSDL is evaluated and a message displays whether the WSDL is valid.

   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.

5. Click Next. At the Select Service panel, select a WSDL service from the imported file.
6. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **info.version** property of the API's OpenAPI definition. The **version.release.modification** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
7. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **X-IBM-Client-Id** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM® API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **cors** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **cors** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **request.attributes.isCORSPreflight** flag is set to **true**.
     - For all preflight requests, the **security** and **client-identification** preflow policies are always skipped, whether CORS is enabled or not enabled.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.

- You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
- To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

9. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

   If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

10. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a REST API definition by using an existing WSDL file.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

You can also manage the Product lifecycle, and control who can see and subscribe to your Product, by opening the Sandbox Catalog associated with your API in the Manage page of the API Designer UI.

Creating a SOAP proxy API from an existing WSDL service

If you have a SOAP service defined in a WSDL file, you can use the WSDL file to create an API Connect SOAP proxy API that calls that SOAP service.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

Note: By default, the SOAP proxy API that is created will have the basepath set to the WSDL service name. You can edit the SOAP proxy API to change this basepath.
You can add a SOAP API to expose an existing SOAP service by supplying the WSDL file that defines that existing service in one of the following ways:

- If the WSDL file is a stand-alone file with no external dependencies, you can load the .wsdl file from a directory to create the SOAP API definition.
- You can provide one or more WSDL files in a single .zip file that contains the WSDL files and any necessary schemas.
  If the WSDL file references other WSDL files or references XSD files containing XML schema definitions, you must create a .zip archive of the WSDL file and its dependent documents, and then load the .zip file from a directory to add the SOAP API definition.

- If you are using API Designer with existing APIs that were created from a WSDL or WSDL.zip file in Version 5 API Designer, make sure that the following requirements are met:
  - The WSDL or WSDL.zip file must be stored in the same directory as the API's YAML file.
  - In the API's YAML file, the **`x-ibm-configuration`** --> **`wsdl-definition`** --> **`wsdl`** property must point directly to the WSDL or WSDL.zip file with no path specified (the files are located in the same directory).

The service must support Web Services Basic Profile Version 1.1 - Second Edition.

Procedure

To add a SOAP API definition by loading a WSDL file, complete the following steps:

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.

2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. Select From existing WSDL service (SOAP Proxy). Click Next.
   The Create API from Existing WSDL Service (SOAP Proxy) window opens.
4. To upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, you can either drag and drop your file, or browse and select the file that you want to use.
   After you upload the file, the WSDL is evaluated and a message displays whether the WSDL is valid.

   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.

5. Click Next. At the Select Service panel, select a WSDL service from the imported file.
6. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
7. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM® API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
9. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

   If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

10. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You created a SOAP API definition by using an existing WSDL file.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

You can also manage the Product lifecycle, and control who can see and subscribe to your Product, by opening the Sandbox Catalog associated with your API in the Manage page of the API Designer UI.

Creating a new REST OpenAPI definition

You can create and edit draft REST API definitions by using the API Designer or the API Designer user interface in IBM® API Connect.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

To create a new REST OpenAPI definition, complete the following steps.

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. Select New OpenAPI .
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
5. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. If selected, you can then select whether to limit the API calls on a per key (per Client ID) basis:
     - Limit API calls on a per key basis - If selected, you must configure the rate limit that you require. Rate limits control the maximum number of calls allowed within a time period (hour, minute, month or day). For example, 100 calls per hour.

     For information about security options in IBM API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain. Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
6. Click Next to create your API definition.
   The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.
7. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

You successfully created a REST API definition. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Adding a REST API by importing an OpenAPI definition file

You can use an OpenAPI definition file to import a REST API into IBM® API Connect.

Before you begin

Your file must conform to version 2.0 or version 3.0 of the OpenAPI specification. The format of the file can be JSON or YAML.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Api-Drafts:Edit`, `Settings:View`, and `App:View` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

If you are using the API Designer UI and you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, use the import mechanism described here rather than copying the file into your local API Designer directory; the import operation adds API Connect specific sections that are required by API Designer.

Procedure

To add a REST API by importing an OpenAPI file, complete the following steps:

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. In the Import section, select Existing OpenAPI, then click Next.
4. Choose one of the following methods for importing the file:
   - Drag and drop a file
     Open another window, select a file. Drag the file to the Select a file box, and release the file.
   - Browse for a file
     Click the Select a file box. Locate the file and select it.
   - Specify the URL of a file
     In the Or specify a file URL field, type or paste a URL for the file. Optionally add a User name and Password if they are required for accessing the file.

   The following file types are supported if they contain a valid OpenAPI definition: .json, .yml, and .yaml.
5. Click Next to import the selected file.
   The wizard checks the validity of the YAML, and displays a message indicating successful validation.

   Notes:
   - If you are using the API Manager UI, the import operation fails if the file defines an API that has the same name and version as an existing API definition. However, if you are using the API Designer UI, API definitions are uniquely identified by the file name in your local file system; therefore, if you import two different files that define the same API name and version, two API definitions with the same name and version are created in API Connect, with no error.
   - Any validation error messages are displayed in English only, and are not translated.
6. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating

custom roles.

7. Click Next. The Import API Summary panel indicates that the YAML file is loaded and valid.
   If you selected Activate API, the wizard populates an API Endpoint URL, and displays a Client ID and Client Secret that you can use.

8. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

When the API definition has been imported, it is shown in the list of API definitions in the Develop page. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

Adding a SOAP API by importing a zip file

You can use an OpenAPI definition file to import a SOAP API into IBM® API Connect.

Before you begin

The format of the file must be .zip, and the file must contain the WSDL definition and the YAML file that defines the API. The YAML file must conform to version 2.0 of the OpenAPI specification.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

If you are using the API Designer UI and you want to use an OpenAPI definition file from elsewhere, downloaded from an external website for example, rather than created by using API Connect, use the import mechanism that is described here rather than copying the file into your local API Designer directory; the import operation adds API Connect specific sections that are required by API Designer.

For more information on how to create a .zip file, see Downloading an API definition.

Procedure

To add a SOAP API by importing a .zip file, complete the following steps:

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. In the Import section, select Existing OpenAPI, then click Next.
4. To import a file from your local file system, you can either drag and drop the file or click the link to select the file from your local file system.
   The wizard checks the validity of the WSDL and YAML, and displays a message that indicates a successful validation.
   Note:
   - If you are using the API Manager UI, the import operation fails if the file defines an API that has the same name and version as an existing API definition. However, if you are using the API Designer UI, API definitions are uniquely identified by the file name in your local file system; therefore, if you import two different files that define the same API name and version, two API definitions with the same name and version are created in API Connect, with no error.
   - Any validation error messages are displayed in English only, and are not translated.
5. Click Next.

6. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
7. Click Next. The Import API Summary panel indicates that the file is loaded and valid.
   If you selected Activate API, the wizard populates an API Endpoint URL, and displays a Client ID and Client Secret that you can use.

8. Select one of the following options:
   - To further configure your API, click Edit API. For details, see Editing an API definition.
   - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Results

When the API definition has been imported, it is shown in the list of API definitions in the Develop page. For API Designer, the specifications for the APIs and Products are stored in the directory that you specified when you logged in. For API Manager, the specifications for the APIs and Products are stored on the management server.

What to do next

APIs are made available to application developers by including them in a Product, and then publishing that Product to a Catalog. For more information, see Working with Products and Working with Catalogs.

API Gateway only

Creating a GraphQL proxy API

GraphQL is a query language for APIs that gives an application client greater control over what data it retrieves in an API request when compared with a REST API request. IBM® API Connect enables you to create a GraphQL API proxy definition that proxies a backend GraphQL server, and to define rate limiting controls that reflect the amount of data that is returned from the server by a request to the GraphQL API.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`**, **`Settings:View`**, and **`App:View`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.

GraphQL provides the following particular advantages over REST APIs:

- The application client can request only the data that it needs. For example, when retrieving bank account records, request only the account number and current balance for each account, but not the customer name and address details. With a REST API request, either the backend REST service must provide separate endpoints for different data subsets, or the application client must retrieve the complete records and then discard the unwanted data.
- The application client can retrieve multiple related resources in a single request. For example, a customer's bank account record might include an array that references other finance products that the customer holds. If an application client wants to retrieve the bank account details for a specific customer, and details of the other finance products for that customer, then with a REST API the client would first retrieve the bank account details, then make separate requests for each of the other products. A GraphQL API can be designed to allow the client to retrieve all this information in a single request.

However, this flexibility presents rate limiting challenges, because two seemingly very similar requests might return vastly different amounts of data, and what might have required multiple REST API requests, each counting towards the rate limit, might require only a single GraphQL API request. It is important therefore that rate limiting controls are imposed that reflect the amount of data that is retrieved. API Connect extends the GraphQL standard by providing, in a GraphQL API definition, the ability to configure a range of settings that are used to calculate the complexity of a GraphQL request and an associated cost that counts towards the rate limit.

Procedure

To create a GraphQL API proxy definition, complete the following steps:

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0; this API type does not support OpenAPI 3.0.
3. Select From existing GraphQL service (GraphQL proxy).
4. Click Next. Specify the API summary in the Info section. You can fine-tune the API after it is created.
   - The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is entered automatically. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - The Version corresponds to the value of the **`info.version`** property of the API's OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - The Base path is the URL segment of the API and does not include the host name or any additional segments for paths or operations. The base path cannot include special characters and must begin with a "/" character even if it is otherwise empty.
   - The optional Description helps to identify the API.
5. In the GraphQL Server section, specify the following values:
   - GraphQL server URL: this is the URL that is used for requests to the backend GraphQL API. The GraphQL schema is imported automatically from the specified URL.
   - Schema name: the name that you enter here is used to identify the schema definition that is created from the imported GraphQL schema. The field is pre-populated with host name segment of the value entered in the GraphQL server URL field, but you can change it.
6. Click Next. If there are any warnings indicated relating to the imported schema, you can review them now by clicking View.
   You can deal with these warnings as appropriate after you have created your GraphQL proxy API.
7. In the Operations and Paths section, select the operations and paths that you want to include.
   The operation path of **`/graphql`** is already selected and you cannot change this setting; this is the path for application client requests to API Connect that invoke the GraphQL API.

   For details of the mechanisms supported for sending a request to the **`/graphql/cost`** endpoint, see Request mechanisms supported by GraphQL endpoints.

   You can also select the operation path of graphql/cost; this path enables application clients to obtain details of the cost of a request to the GraphQL API before making the actual request. In a production environment, in particular, you should consider carefully the resource implications of making this path available. For full details regarding the enablement of the cost endpoint, see Enabling the cost endpoint for a GraphQL API.

   To form the full API paths, these path segments are appended to the **`basepath`** that you specified in step 4.

   To allow application clients to send introspection requests for this GraphQL proxy API, select Support default introspection. For full details, see Supporting introspection for a GraphQL API.

   To allow users to test the GraphQL proxy API from a GraphiQL editor, select Enable GraphiQL editor. For full details, see Enabling the GraphiQL editor for a GraphQL API.

   Note: The graphql/cost, Support default introspection, and Enable GraphiQL editor options each automatically generate policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required.
8. Optionally, you can replace the GraphQL schema that was imported from the GraphQL server URL by uploading a schema from your local file system. Click Replace; you can then either drag and drop your file, or click where indicated to select the file from your local file system. Click Upload when done.
   Note:
   - The schema must be written in the GraphQL Schema Definition Language (SDL). For more information, see Type language in the GraphQL documentation at https://graphql.org/.
   - If you upload a schema from a local file having previously uploaded a schema from a URL, the schema URL setting that is stored in the OpenAPI source for the API, and subsequently displayed in the user interface, retains the previously specified URL value rather than indicating a file location.
9. Click Next. In the Secure section, configure the API security that you require.
   - Secure using Client ID - Select this option to require an Application to provide a Client ID (API Key). This causes the **`X-IBM-Client-Id`** parameter to be included in the request header for the API. For information about security options in IBM API Connect, see Configuring API security.
   - CORS - Select this option to enable cross-origin resource sharing (CORS) support for your API. This allows your API to be accessed from another domain.
     Note:
     - CORS support is available only on the DataPower® API Gateway.
     - When CORS is enabled, the API Gateway runs the **`cors`** preflow policy to handle all CORS requests that are made to the API.
     - When CORS is enabled and a preflight request is received, only the following API actions are performed:
       - The **`cors`** preflow policy configures the appropriate response headers.
       - The response headers are set.
     - When a preflight request is received, the **`request.attributes.isCORSPreflight`** flag is set to **`true`**.
     - For all preflight requests, the **`security`** and **`client-identification`** preflow policies are always skipped, whether CORS is enabled or not enabled.
10. Optional: Select Activate API if you want to immediately use the API for further development and testing.
    Note:
    - When you select the Activate API option, API Connect automatically completes the following actions:
      - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
      - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
    - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
    - To use the Activate API option, you must be assigned a role that has the **`Product:Manage`** and **`Subscription:Manage`** permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
11. Click Next to create your API definition.
    The Summary panel displays messages as the definition is created, and the selected security options are enforced.

    If you selected Activate API, the wizard populates an API Endpoint URL that you can use in testing. If you have also selected Secure using Client ID, the wizard displays a Client ID and Client Secret you can use.

12. Click Next to create your API definition.
    The Summary panel displays messages as the definition is created, and the selected security options and rate limits are enforced.

13. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

What to do next

Use the GraphQL schema editor to review, and deal with, any warnings associated with the schema, and to configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit; for details, see Using the GraphQL schema editor.

- **Using the GraphQL schema editor**
  The GraphQL schema editor allows you to a configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit.
- **Supporting introspection for a GraphQL API**
  If you select the Support default introspection option when creating a GraphQL proxy API, client applications can send GraphQL introspection requests to the API.
- **Enabling the GraphiQL editor for a GraphQL API**
  If you select the Enable GraphiQL editor option when creating a GraphQL proxy API, users can test the API by using a GraphiQL editor in a web browser; API Connect responds to the initial GraphiQL editor request with an HTML page that enables testing from the GraphiQL editor.
- **Enabling the cost endpoint for a GraphQL API**
  If you enable the `/graphql/cost` endpoint when creating a GraphQL proxy API, a calling application can obtain details of the cost of executing a request on the backend GraphQL server before making the actual backend request.
- **Securing a GraphQL API by using a client ID**
  If you select the Secure using Client ID option when creating a GraphQL proxy API, API Connect automatically adds Rate limit policies to the API assembly.
- **Request mechanisms supported by GraphQL endpoints**
  API Connect supports various mechanisms for sending requests to GraphQL proxy API endpoints.
- **GraphQL custom schema directives and scalar types**
  The API Connect DataPower API Gateway extends the GraphQL specification by providing additional schema directives and custom scalar types.
- **@remove directive**
  The `@remove` GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context.
- **GraphQL limitations**
  This page details the limitations in the API Connect GraphQL implementation for the current release.

API Gateway only

Using the GraphQL schema editor

The GraphQL schema editor allows you to a configure a range of settings that are used to calculate the complexity of a GraphQL request, and an associated cost that counts towards the rate limit.

Introduction

When the GraphQL schema editor opens, all the types defined in the GraphQL schema are listed. You can expand a type to display all the fields that are defined for that type.

For each type, you can specify the following setting:

Type weight
: The weighting factor that you want to apply to the type for use when calculating the type cost for a request to the GraphQL API. In general, the weighting factor for a type will reflect the resource implications for a request that retrieves values of that type; for example:

  - A complex object might be weighted more heavily than a String.
  - Values of one type might be retrieved from a different backend database to values of another type, and accessing one database requires more CPU resource, so types associated with this database are weighted more heavily.

For each field, you can specify the following settings:

Field weight
: The weighting factor that you want to apply to the field for use when calculating the field cost of a request to the GraphQL API.

Assumed size
: The size limit that the backend server imposes on the number of values of this field that are returned, in a list, for each separate retrieval of the field in an API request. If an assumed size has been defined for this field in the imported GraphQL schema, its value is displayed. You an enter a value, or change the current value, and the schema definition stored in API Connect is updated accordingly. You must ensure that the specified value corresponds with the implementation or configuration on the backend server so that API Connect can apply rate limiting correctly. The assumed size is intended to be configured for fields that return lists of values, to tell the cost analysis how many values to expect.

Slicing arguments
: A comma separated list of the arguments that are used by the backend server to limit the number of values of this field that are returned, in a list, for each separate retrieval of the field in an API request. These must correspond with the implementation or configuration on the backend server. For example, there might be slicing arguments of `first` and `last` that are used to specify a range of objects to be returned by an API request.

Sized fields
: In some cases, a field with a configured Assumed size or Slicing arguments setting returns an object, a field of which returns the values whose number is to be sized. This is common in the connections pattern for pagination, where fields with slicing arguments `first` or `last` return a `connections` object, that contains the sized list in an `edges` field. The Sized fields option allows the cost analysis to consider these indirect relationships between assumed sizes or slicing arguments and the sized list of values. Supply a comma separated list of field names.

You access the GraphQL schema editor in either of the following ways:

- Immediately after creating a new GraphQL proxy API , by clicking Edit API, then clicking the GraphQL Schema tab. For GraphQL proxy API creation details, see Creating a GraphQL proxy API.
- By modifying the configuration of an existing API; complete the following steps:
  1. In the navigation pane, click Develop, then select the APIs tab.
  2. Alongside the GraphQL API definition that you want to work with, click the options icon and then click Edit API.
  3. Click the GraphQL Schema tab.

Modifying a setting for a single type or field

For a numerical setting, click the setting alongside the required type or field, then enter the required value, or use the stepper control. For a setting that has a textual value, enter the value directly. You might first want to filter the display to show only a relevant subset of types and fields; see Filtering the display.

Modifying settings for multiple types and fields

To modify settings for multiple types and fields in a single operation, complete the following steps:

1. Select the check boxes alongside the types and fields whose settings you want to modify.
2. Click Apply analysis configuration.
3. On the Type tab, specify the settings that you want to apply to the selected types.
4. On the Field tab, specify the settings that you want to apply to the selected fields.
5. Click Apply to apply the settings to the selected types and fields.
6. When you have made all the required modifications to the selected types and fields, click Done; this actions clears all check box settings.

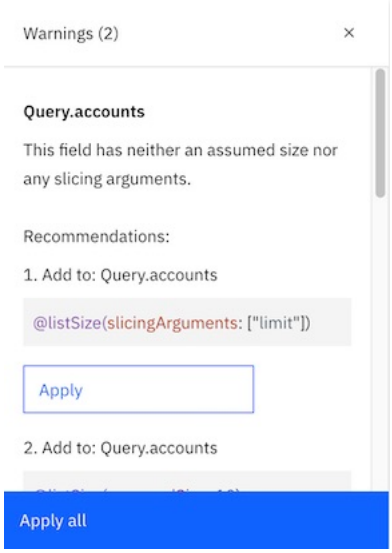
To to restore any type or field settings to the initial default settings after having applied an analysis configuration, select the check boxes alongside the required types and fields, then click Remove analysis configuration.

You might first want to filter the display to show only a relevant subset of types and fields; see Filtering the display.

Filtering the display

To display only those type and fields that contain a specified string, enter the required filter string in the Search schema field, then press Enter.

If a type matches the filter, the type and all its fields are displayed. If a field matches the filter but not its parent type, the parent type is displayed together with all matching fields. You can enter multiple filter strings; the items displayed are those that contain all strings.



You can now use the operations described in Modifying a setting for a single type or field and Modifying settings for multiple types and fields to update the settings for the displayed types and fields.

To remove a specific filter string from the search, click the Close icon for that filter string. To restore the full type and field display by removing all filter strings, click the Clear icon at the end of the search field.

GraphQL schema warnings

Where applicable, API Connect will recommend updates to the analysis configuration to protect the backend server from excessive resource utilization, and to ensure correct cost estimation for requests. These recommendations are displayed as warnings in the GraphQL schema editor.

If a type contains one or more fields with warnings, this is indicated by a warning count icon 2 alongside the type. You can click the warning count icon to see the warnings for that type; the Warnings window opens at the relevant warnings, for example:

To see the fields that have warnings, expand the type; a warning icon is displayed alongside fields with warnings. To see the details of a warning for a field, click the warning icon alongside the field

If you click Accept under any warning in the Warnings window, the recommended update is applied to the schema automatically.

To apply the suggested updates for all warnings in a single operation, click Apply all in the Warnings window, then click Apply to confirm.

You can filter the display to include only items with warnings; click the Menu icon, then select Show warnings only.

Applying @remove directives to types and fields in the GraphQL schema

The **`@remove`** GraphQL schema directive specifies conditions for removing items from validation or introspection for each transaction based on values in the API context. For example, you can prevent specific Plans from using certain types or fields.

For more details on the **`@remove`** directive, including examples, see rapic_graphql_extensions.html#reference_wrt_bk1_5mb__at_remove.

To apply an **`@remove`** directive to an item in your GraphQL schema, complete the following steps:

1. Click the settings icon in the Show/hide column alongside the required item. The Show/hide settings window opens.
2. To remove the item depending on a boolean condition, enter the boolean expression in the Custom expression field; the following directive will be added to the item in the schema:

   ```
   @remove(if: [expression])
   ```

   To remove the item unconditionally, change the Show in schema slider control to Hide in schema; the following directive will be added to the item in the schema:

   ```
   @remove(if: ["true"])
   ```

3. Click Next. A summary window opens. If the removal is permitted, any related items that will also have the **`@remove`** directive applied are listed; for example, if you apply an **`@remove`** directive to a type, and that type is referenced as the data type of a field on another type, the **`@remove`** directive is also applied to that field. If the removal is not permitted, an explanation is displayed.
4. If the removal is permitted, click Done to apply the **`@remove`** directive. If the removal is not permitted, either click Cancel to close the window or click Back and amend your settings.
5. To see the updates to the GraphQL JSON schema, click View source.

You can use the settings icon to modify or delete previously applied **`@remove`** directives. To remove a conditional **`@remove`** directive, delete the expression from the Custom expression field. To remove an unconditional **`@remove`** directive, change the Hide in schema slider control to Show in schema.

Viewing the GraphQL schema

To view the GraphQL JSON schema that was previously uploaded, click View source. Note that the schema includes **`directive`** statements and attribute values, added by API Connect, that reflect the configuration settings.

Replacing the GraphQL schema

To replace the GraphQL schema, complete the following steps:

1. Click Replace.
2. Specify the replacement schema:
   - To replace the schema by introspecting a URL, complete the following steps:
     - Select Introspect from URL.
     - Enter the URL in the GraphQL server URL field, then click Introspect.

     Note: If you replace the schema from a URL that is different to the one specified as the backend GraphQL server, in the GraphQL server URL field, when the GraphQL proxy API was created, the schema itself is replaced but the backend URL remains unchanged. You must correspondingly modify the URL setting on the **`invoke`** policy in the API assembly of your GraphQL proxy API.
   - To replace the schema by uploading a file, complete the following steps:
     - Select Upload schema definition language (SDL) file.
     - Either drag and drop the file or click the link to select the file from your local file system.

     Note:
     - The schema must be written in the GraphQL Schema Definition Language (SDL). For more information, see Type language in the GraphQL documentation at https://graphql.org/.
     - If you upload a schema from a local file having previously uploaded a schema from a URL, the schema URL setting that is stored in the OpenAPI source for the API, and subsequently displayed in the user interface, retains the previously specified URL value rather than indicating a file location.

   All the changes between the replacement schema and the current schema are listed.
3. Update the schema as required:
   - To have all new types and fields shown by default, select New schema for the Update schema defaults giving preference to setting. You can then choose to hide specific items by selecting Hide in the Action column alongside an item. Hiding an item causes an **`@remove`** directive to be added to the item in the schema source, as detailed in Applying @remove directives to types and fields in the GraphQL schema.
   - To have all new types and fields hidden by default, select Old schema for the Update schema defaults giving preference to setting. You can then choose to show specific items by selecting Show in the Action column alongside an item.

   Note: If the current schema contains items that are not in the replacement schema, these items are deleted. Such deletions are shown in the change listing with the Accept setting displayed in the Action column; you cannot change this setting.
4. Click Next. A change summary page is displayed. If any removals are not permitted, an explanation is displayed, and you cannot complete the schema replacement; either click Cancel to close the window or click Back and amend your settings..
5. Click Submit to complete the schema replacement.

Downloading the GraphQL schema

To download the GraphQL schema to a local file, click the Download. Note that the downloaded schema includes all additional settings that reflect your configuration updates.

API Gateway only

Supporting introspection for a GraphQL API

If you select the Support default introspection option when creating a GraphQL proxy API, client applications can send GraphQL introspection requests to the API.

Introspection allows client applications to request details of all the types and fields that are defined in a GraphQL schema. When you create a GraphQL proxy API, introspection requests sent to that API from client applications are handled by the gateway. The response reflects any modifications you have made to the schema by using the GraphQL schema editor.

When you select the Support default introspection option, API Connect creates the introspection endpoint. A GraphiQL editor always attempts to introspect a GraphQL endpoint, so disabling this option significantly reduces the test capability for GraphiQL editor users. This option also automatically generates policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required; see the API assembly policies for introspection support section for details. Disabling this option also limits the capability of the Developer Portal to test the GraphQL proxy API.

On the other hand, providing introspection support can have resource implications, and you might choose to communicate the schema information in another way. However, note that the GraphiQL editor does not allow custom introspection queries to populate the document explorer. For more information on introspection, see Introspection in the GraphQL documentation at https://graphql.org/.

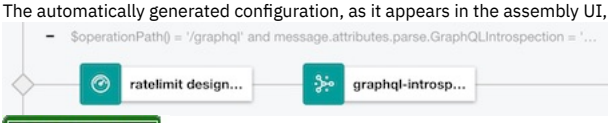
API assembly policies for introspection support

This section details the API assembly policy configuration that is generated automatically if the Support default introspection option is selected when a GraphQL proxy API is created. If the option is not selected at creation time, and you later decide that you want to enable it, you must add it manually to the API assembly.

A `case` is added to a `switch` policy with the following condition:

```
($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'standard-introspection')
```

If the condition is true, the following policies are executed in sequence, with property settings as indicated:



Rate limit

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

GraphQL introspect

Property	Value
Input	message
Output	No value, defaults to input

The automatically generated configuration, as it appears in the assembly UI, is as follows:

API Gateway only

Enabling the GraphiQL editor for a GraphQL API

If you select the Enable GraphiQL editor option when creating a GraphQL proxy API, users can test the API by using a GraphiQL editor in a web browser; API Connect responds to the initial GraphiQL editor request with an HTML page that enables testing from the GraphiQL editor.

Disabling the Enable GraphiQL editor option reduces gateway traffic and latency and, furthermore, the Developer Portal provides equivalent test capability regardless of whether or not you enable the option.

This option automatically adds the following property setting to the OpenAPI source for the GraphQL proxy API:

```
html-page: 'store:///graphiql.html'
```

If you disable the Enable GraphiQL editor during API creation and later decide that it is required, you can either manually add this property setting, or you can select Enable GraphiQL editor on the API Setup page of the Design tab of the API..
Note:

- The `html-page` property should be used **only** with a GraphQL proxy API.
- `store:///graphiql.html` is the only value allowed for the `html-page` property.
- If you add the `html-page` property but the Support standard introspection property was not enabled during API creation, the GraphiQL HTML page will not show any documentation regarding the GraphQL backend server, perform query validation, or perform smart lookup. For details on how to manually create the required assembly policy configuration, see Supporting introspection for a GraphQL API.

API Gateway only

Enabling the cost endpoint for a GraphQL API

If you enable the **/graphql/cost** endpoint when creating a GraphQL proxy API, a calling application can obtain details of the cost of executing a request on the backend GraphQL server before making the actual backend request.

The "cost" does not relate purely to monetary cost but can take into account factors such as computational time, memory consumption, and other such factors, in addition to the actual financial costs associated with, say, using third-party systems to retrieve data.

In a production environment, in particular, you should consider carefully the resource implications of making this path available. Note, however, that enabling the **/graphql/cost** endpoint automatically generates policy configuration in your API assembly that would have to be created manually if you disable this option and later decide that it is required; see the API assembly policies for the cost endpoint section for details.

API assembly policies for the cost endpoint

This section details the API assembly policy configuration that is generated automatically if the **/graphql/cost** operation path is selected when a GraphQL proxy API is created. If the path is not selected at creation time, and you later decide that you want to enable it, you must add it manually to the API assembly.

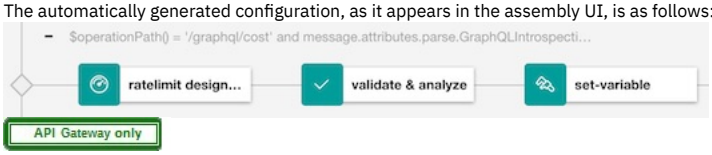
A **case** is added to a **switch** policy with the following condition:

```
($operationPath() = '/graphql/cost' and message.attributes.parse.GraphQLIntrospection = 'not-introspection')
```

If the condition is true, the following policies are executed in sequence, with property settings as indicated:

Rate limit

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume



Validate

Property	Value
Input	message
Output	No value, defaults to input
Validate against	GraphQL

Set Variable

Property	Value
Action	Set
Set	message.body
Type	any
Value	$(message.attributes.graphql)

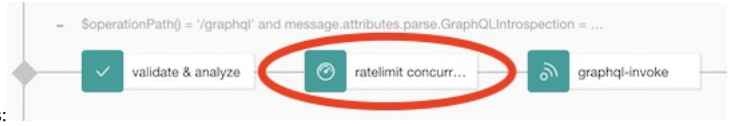
The automatically generated configuration, as it appears in the assembly UI, is as follows:

Securing a GraphQL API by using a client ID

If you select the Secure using Client ID option when creating a GraphQL proxy API, API Connect automatically adds Rate limit policies to the API assembly.

This section details the Rate limit policy configuration that is generated automatically. If the Secure using Client ID option is not selected at creation time, and you later decide that you want to enable it, you must add the appropriate Rate limit policies manually to the API assembly.

The automatically generated Rate limit policies are added to the **switch** cases in the assembly as follows:



- **switch** case:

  ```
  ($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'not-introspection' and
  message.attributes.graphql.operationType = 'subscription')
  ```

  A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Count Limit Name	graphql-subscription-type-cost
Operation	Increment
Count Limit Name	graphql-subscription-field-cost
Operation	Increment

  The policy as it appears in the assembly UI is as follows:

  This Rate limit policy limits the number of HTML web browser requests for a GraphiQL editor sent to the **/graphql** endpoint.

- **switch** case:

```
($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'not-introspection' and
message.attributes.graphql.operationType != 'subscription')
```

Two Rate limit policies with the following property settings:

- Policy 1:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-type-cost
Operation	Consume
Rate Limit Name	graphql-field-cost
Operation	Consume
Rate Limit Name	graphql-input-type-cost
Operation	Consume

This Rate limit policy limits calls to the GraphQL proxy API by calculating the expected cost of the query, and then correspondingly reducing the available cost balance that remains of the total configured cost limit. The expected cost is calculating by applying the weighting factors that have been attached to the types and fields in the GraphQL schema; for more information, see Using the GraphQL schema editor.

The expected cost is calculated by the Validate policy that precedes the Rate limit policy and placed in the API context to be made available to the Rate limit policy. For details on the Validate policy, see Validate.

The details of the cost calculations to which the referenced rate limits are applied are as follows:

- **`graphql-field-cost`**: The weighted sum of fields being selected in a query. Fields that return values of scalar or enum types have a weight of 0.0 and therefore don't affect field cost.
  For example, consider the following query, where it is assumed that the value **`max`** in the **`filter`** argument of field **`Query.offices`** constrains the number of **`Office`** objects being returned:

  ```
  query {
    offices (filter: {location: "NY", max: 3}) {
      address {
        street
      }
    }
  }
  ```

  The **`Address.street`** field is of type **`String`** and therefore has a weight of 0.0. Non scalar and non enum field weights that are not changed in the GraphQL schema editor assume a default value of 1.0. If the **`Office.address`** field weight has been set to 3.0, the total field cost is 10.0, calculated as follows:

Field	Weight	Field cost
`Query.offices`	1.0	1 x 1.0 = 1.0
`Office.address`	2.0	3 x 3.0 = 9.0
`Address.street`	0.0	0.0
	Total cost:	1.0 + 9.0 + 0.0 = 10.0

- **`graphql-type-cost`**:
  The weighted sum of types being returned by a query. Scalar or enum types have a weight of 0.0 and therefore don't affect type cost.

  Considering the previous example, and assuming that all types have a default weight of 1.0, the total type cost is 7 (1 x **`Query`** type + 3 x **`Office`** types + 3 x **`Address`** types.

- **`graphql-input-type-cost`**:
  The weighted sum of input types being sent in a query. Scalar or enum input types have a weight of 0.0 and therefore don't affect input type cost.

  Considering the previous example, the input type cost is 1.0, because one **`FilterInput`** type is sent in the **`filter`** argument.
  `FilterInput.location` is a **`String`** type and **`FilterInput.max`** is an **`Int`** type, so they are not included as they are scalars.

- Policy 2:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-type-cost
Operation	Replenish
Rate Limit Name	graphql-field-cost
Operation	Replenish

This Rate limit policy limits calls to the GraphQL proxy API by calculating the actual cost of the query, and then correspondingly reducing the available cost balance that remains of the total configured cost limit. The actual cost is calculating by applying the weighting factors that have been attached to the types and fields in the GraphQL schema; for more information, see Using the GraphQL schema editor.

Note that if the actual cost is less than the expected cost, this Rate limit policy will appropriately restore some of the available cost balance that had been removed by Policy 1, thereby overriding the original actual cost limitation. The actual cost might be less than the expected cost if, for example, the query requested more data than was available in a backend database. You can delete one or other of these Rate limit policies from the assembly if desired.
Note: Such unused cost is **not** restored if there are GraphQL response errors. The purpose of this restriction is to prevent malicious requests that cause large amounts of erroneous backend processing while only using a small amount of cost.
The actual cost is calculated by the Validate policy that precedes the Rate limit policy and placed in the API context to be made available to the Rate limit policy. For details on the Validate policy, see Validate.

The policies as they appear in the assembly UI are as follows:

- **`switch`** case:

  `($operationPath() = '/graphql/cost' and message.attributes.parse.GraphQLIntrospection = 'not-introspection')`

  A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

  The policy as it appears in the assembly UI is as follows:

  This Rate limit policy limits the requests sent to the **`/graphql/cost`** endpoint for retrieving the cost of a GraphQL query.

- **`switch`** case:

  `($operationPath() = '/graphql' and message.attributes.parse.GraphQLIntrospection = 'standard-introspection')`

  A single Rate limit policy with the following property settings:

Property	Value
Source	Plan by Name
Rate Limit Name	graphql-design-request
Operation	Consume

  The policy as it appears in the assembly UI is as follows:

  This Rate limit policy limits standard introspection requests sent to the **`/graphql`** endpoint.

The rate limits that are referred to by the Rate Limit Name settings in these policies are predefined in Plans that are created in Products that contain one or more GraphQL proxy APIs. You can configure the actual rate limiting values there; for more information, see Editing a draft Product.

For more information on the Rate Limit policy, see Rate Limit.

API Gateway only

Request mechanisms supported by GraphQL endpoints

API Connect supports various mechanisms for sending requests to GraphQL proxy API endpoints.

You can use any of the following mechanisms for sending requests to the **`/graphql`** and **`/graphql/cost`** endpoints on a GraphQL proxy API:

- **`GET`**: the GraphQL query must be specified in a URL query parameter called **`query`**.
  For example:

  `https://hostname/basepath/graphql?query={accounts(limit:100){name{first,last}}}`

  The following example includes the **`variables`** and **`operationName`** properties, with URL encoding:

```
https://hostname/basepath/graphql?
query=query%20fetchAccounts%20($limit:%20Int)%20{accounts(limit:%20$limit)%20{name{first,last}}}&variables=
{"limit":100}&operationName=fetchAccounts
```

- **`POST`** with a JSON-encoded body: the **`Content-Type`** header must be set to **`application/json`**, and the GraphQL query must be sent in the **`query`** key of the JSON object.
  For example:

```
{
  "query": "query fetchAccounts ($limit: Int) {accounts(limit: $limit) {name{first,last}}}",
  "variables": {"limit": 100},
  "operationName": "fetchAccounts"
}
```

  The **`variables`** and **`operationName`** are optional. For more information, see POST request in the GraphQL documentation at https://graphql.org/..

- **`POST`** with graphql content: the **`Content-Type`** header must be set to **`application/graphql`**; the entire body of the **`POST`** is treated as the GraphQL query

Note: For a request sent to the `/graphql` endpoint, the GraphQL proxy API always sends the request to the backend GraphQL server as a `POST` with a JSON-encoded body, so the backend GraphQL server must support this mechanism otherwise the call fails.

GraphQL custom schema directives and scalar types

The API Connect DataPower® API Gateway extends the GraphQL specification by providing additional schema directives and custom scalar types.

Custom schema directives

`@cost`
: The `@cost` directive associates weight values with types or fields. Types are used to calculate type cost of a request to the GraphQL API. Fields are used to calculate field cost of a request to the GraphQL API. For more information, see The Cost Directive.

`@listSize`
: The `@listSize` directive applies slicing arguments to fields. For more information, see The List Size directive.

`@remove`
: The `@remove` GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context. For more information, see @remove directive

`@scalarParam`
: The `@scalarParam` directive allows further customization of custom scalar types. For more information, see @scalarParam directive.

Custom scalar types

`Date`
: The `Date` custom scalar type is used to define custom scalars that specify dates. For more information, see Date Custom Scalar.

`DateTime`
: The `DateTime` custom scalar type is used to define custom scalars that specify date and time. For more information, see DateTime Custom Scalar.

`JSON`
: The `JSON` custom scalar type is used to specify JSON payloads. For more information, see JSON Custom Scalar.

`Long`
: The `Long` custom scalar type enables the use of integers larger than those allowed by `Int`. For more information, see Long Custom Scalar.

Related reference

- Using the GraphQL schema editor

`@remove` directive

The `@remove` GraphQL schema directive specifies conditions for removing types and fields from validation or introspection for each transaction based on values in the API context.

For example, you can prevent specific Plans from using certain types or fields. For more information on the API context, see API Connect context variables.

Note: The `@remove` directive dynamically modifies the schema so that queries that do not conform to the schema, after any `@remove` directives have been evaluated, would be rejected by a `validate` policy.

Syntax

```
@remove(if: [String]) on SCALAR | OBJECT | FIELD_DEFINITION | ARGUMENT_DEFINITION | INTERFACE | UNION | ENUM | ENUM_VALUE | IN
```

Arguments

Argument name	Type	Description
`if`	List of strings	JSONata condition that specifies the criteria for removal of a type or field from validation or introspection.

Limitations and propagation rules
: For limitations and propagation rules, see Limitations and propagation rules for the GraphQL `@remove` directive.

Example 1
: Remove the `creditCard` type if the current API plan is `bronze`.

```
type creditCard @remove(if: ["plan.name in [\"bronze\"]"])
```

Example 2
: Remove the `creditCard` type if the current API plan is not `gold`, and remove the field `card1` if the API plan is `bronze`.

```
type creditCard @remove(if: ["$not(plan.name = \"gold\")"]){
   field1: String
}
type User {
  card1: creditCard @remove(if: ["plan.name = 'bronze'", "$not(plan.name = \gold\")"])
}
```

API Gateway only

GraphQL limitations

This page details the limitations in the API Connect GraphQL implementation for the current release.

- Specialized handling of custom scalars is not supported, except for validation of the `Long` custom scalar type. Input values provided for all other custom scalar types are passed through.
- The following actions and functions cannot read or write to parsed GraphQL queries. Some of these policies might read and write a serialized form of the GraphQL query.
  - Assembly GatewayScript policy
  - Assembly Map policy
  - Assembly Redaction policy
  - Assembly Set Variable policy
  - Assembly XSLT policy
  - `setVar()` function
- When reading parsed GraphQL queries, the Assembly Switch policy cannot use wildcards or read arguments.
- GraphQL schemas cannot be serialized.
- GraphQL messages received with `Content-Type: application/graphql` or `Content-Type: application/json` will send that same content type to the backend. This behavior cannot be overridden.
- All GraphQL schemas are checked for unbounded lists, including those that are not referenced in the assembly. This behavior can cause validation errors that prevent the GraphQL API from being published.
- The GraphQL schema editor generates warnings for fields that contain unbound lists of values if either of the following conditions is true.
  - The values in the list are of composite type. However, the warning is not valid if the composite type in the list has a defined type weight of 0.0 and all its sub-fields also have weights of 0.0 (both the fields and the types of the values they return).
  - The values in the list are of scalar type, for which a weight other than 0.0 was defined.
- Extending schemas is not supported.
- GraphQL APIs can be tested from the Developer Portal user interface. However, not all authentication methods are supported. You must use one of the following authentication methods:
  - Unsecured
  - Client ID, passed in the header
  - Client ID and secret, passed in the header

  Also, `cost` metrics are not supported, and rate limits specific to GraphQL are not listed in Product plans.

Importing an API from the CP4I asset repository

If you are using API Connect with IBM® Cloud Pak for Integration, you can import an API definition from the CP4I asset repository.

About this task

To complete this task you must be assigned a role that has the `Api-Drafts:Edit` permission. The Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select OpenAPI 2.0 or OpenAPI 3.0 according to which version of the OpenAPI specification your API is to be based on.
3. In the Import section, select From asset repository, then click Next.
4. Click Launch the asset repository.
5. From the asset repository listing, click the name of the API that you want to import.
   An API explorer window opens, enabling you to examine the details of the API.
6. Click Create from asset.
   The validity of the API definition is checked, and a message is displayed indicating successful validation.
7. Click Next.
8. Optional: Select Activate API if you want to immediately use the API for further development and testing.
   Note:
   - When you select the Activate API option, API Connect automatically completes the following actions:
     - Creates a draft product, adds the API to the product, and publishes the product to the Sandbox catalog so that the API is available to be called. The product has the title *api_title* auto product. This product is not visible in the Develop view and you cannot delete it directly. However, if you delete the API the draft product is deleted together with the API; see Deleting an API definition. The product is visible in any catalogs to which it is published. If you want to remove the product from a catalog, you must do this separately; see Removing a product from a catalog
     - Subscribes the Sandbox test application to the product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.
   - You cannot use the Activate API option if lifecycle approval is enabled in the Sandbox catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to use the Activate API option they must be disabled; for information on lifecycle approval settings, see Creating and configuring catalogs.
   - To use the Activate API option, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.
9. Click Next.
   The Summary panel displays messages as the API definition is created.
10. Select one of the following options:
    - To further configure your API, click Edit API. For details, see Editing an API definition.
    - If you do not want to configure your API further at this time, click the Develop link in the breadcrumb trail to return to the welcome page; you can then move on immediately to another task. For details on how to configure your API later, see Editing an API definition.

Importing an AsyncAPI from Event Endpoint Management

Import one or more AsyncAPI specifications from Event Endpoint Management.

Before you begin

In this scenario, Event Endpoint Management can be viewed as the authoring tool for your AsyncAPI, as well as the gateway service (and enforcement point provider). API Connect is the place where the API is surfaced, and where events are found and managed. After you import the AsyncAPI, you can use API Connect to package it and offer it to consumers.

Complete the following tasks to prepare your API Connect and the AsyncAPI definition file:

1. Ask your cloud administrator to Register an event gateway service.
2. Add the event gateway to the catalog where you will store the API.
3. To import an individual AsyncAPI to API Connect, first export the YAML file from Event Endpoint Management. To export the YAML file from Event Endpoint Management complete the following steps:
   a. In the Event Endpoint Management UI, navigate to the Topics page, and select the topic you want to export.
   b. Click the Options tab, and then click Export.
   c. Select For IBM API Connect (contains credentials) as the export format, and then click Export.

   For more information, see Exporting an AsyncAPI document for use in API Connect in the Event Endpoint Management documentation.

About this task

To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The Developer role has this permission by default; if you are assigned a custom role that it must have this permission. For more information, see Creating custom roles.

Note: API Designer does not support importing an Async API, you must import the API using API Manager.

Procedure

1. In the navigation pane, click Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select the AsyncAPI tab to indicate the type of API that you want to work with.
3. You can import AsyncAPI definitions into API Connect either individually or in bulk.
4. To import AsyncAPI in bulk, complete the following steps:
   a. In the Create section, select AsyncAPI from Event Endpoint Management, then click Next.
   b. Select the APIs you want to import.
   c. Click Next to import the selected files.
   d. Click Done on the summary page that opens.
5. To import an individual AsyncAPI, complete the following steps:
   a. In the Import section, select Existing AsyncAPI, then click Next.
   b. On the Import from file page, choose one of the following methods for importing the file:
      - Drag and drop a file:
        Open another window and select a file. Drag the file to the Select a file box, and release the file.
      - Browse for a file:
        Click the Select a file box. In the File Upload window, locate the file and select it, and then click Open.
      - Specify the URL of a file
        In the Or specify a file URL field, type or paste a URL for the file. Provide a username and password if they are required for accessing the file.

   c. Click Next to import the selected file.
      The import wizard checks the validity of the YAML, and displays a message indicating successful validation: **`YAML has been successfully validated.`**
   d. Select the Gateway tab and then click Gateway and portal settings > Properties.
   e. Locate the **`bootstrapServerAddress`** property and verify that the Value field is not empty.
      If the field is empty, enter: **`${bootstrapServerAddress}`** before proceeding.
   f. Click Next to create the API.
      The Summary confirms that the new API definition is created.

      The new API is created, published to the sandbox catalog, and made available online (activated) for use. If you want to publish the API to a different catalog, add the Event Gateway Service to the catalog and then publish the API directly to that catalog.

      The summary displays the API's endpoint, and the sandbox catalog's client ID and client secret, which you can use for testing the API.

Results

Using one of the two methods discussed in the topic, you imported the AsyncAPI into API Connect.

Creating an AsyncAPI with Event Endpoint Management

Create an AsyncAPI using Event Endpoint Management.

Before you begin

In this scenario, Event Endpoint Management can be viewed as the authoring tool for your AsyncAPI and the gateway service (and enforcement point provider). API Connect is the place where the API is surfaced, and where events are found and managed. After you create an AsyncAPI, you can package it with API Connect to offer it to consumers.

Complete the following tasks to prepare your IBM® API Connect and Event Endpoint Management:

1. Ask your cloud administrator to Register an event gateway service.
2. Add the event gateway to the catalog where you store the API.
3. In Event Endpoint Management, create a topic and add an option to it. Then, publish the option. This option can be created as an AsyncAPI in API Connect.

About this task

To complete this task, you need a role with the **`Api-Drafts:Edit`**. The Developer role includes this permission by default. If you have a custom role, make sure that it includes this permission. For more information, see Creating custom roles.

Notes:

- AsyncAPI published in Event Endpoint Management is read only i API Connect.
- API Designer does not support creating an AsyncAPI, you must create the API by using API Manager.

Procedure

1. In the navigation pane, click  Develop, then click Add > API.
   The Select API type screen is displayed.
2. Select the AsyncAPI tab to indicate the type of API that you want to work with.
3. In the Import section, select Event Endpoint Management, then click Next.
4. The Add API page opens. Select the API from the instance. Then click Next.
5. The Summary page displays messages as the AsyncAPI is generated.
6. Click Done.

Creating a REST proxy for watsonx.ai with the AI Gateway

Create a REST proxy that uses the AI Gateway to control access to AI models.

Before you begin

Complete the tasks in Prerequisites for using the AI Gateway to ensure that you can authenticate with IBM Cloud and access watsonx.ai.

About this task

The AI Gateway is only supported with OpenAPI 3.0 APIs.

Procedure

1. In the navigation pane, click  .
2. On the Develop page, click Add > API.
3. On the Select API type page, click the OpenAPI 3.0 tab.
4. In the Create section, select AI gateway, then click Next.
5. On the Create API from AI gateway page, use the Platform field to select watsonx as the AI service that the new API will use.
6. Use the "Info" section to provide basic information about the API, and then click Next:
   - The OpenAPI version is based upon the step 3 selection where you clicked on OpenAPI 3.0.
   - Title: The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is filled in for you based on the title. The value is a single string that is used to identify the API in developer toolkit CLI commands.
   - Version: Accept the default value or modify it as needed. The version corresponds to the value of the **`info.version`** property of the OpenAPI definition. The **`version.release.modification`** version numbering scheme is recommended; for example `1.0.0`.
   - Base path: Accept the default value or modify it as needed. The API's "base path" is the server URL, which is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, you only need to provide the base path value. In addition:
     - Do not include the host name or any additional segments for paths or operations
     - Do not include special characters
     - Begin the URL with a forward slash (/) even if it is otherwise empty
   - Description: The optional description helps to identify the API.
7. Provide information for authenticating with watsonx.ai, and then click Next:
   - Project ID: Provide either the ID of the watsonx.ai project used for resolving API requests, or a $(name of a catalog property) whose value is the ID of the watsonx.ai project.

- API key: Provide either the API key of the watsonx.ai server used for resolving API requests, or a $(name of a catalog property) whose value is the API key of the watsonx.ai server.
  The API key allows the API to authenticate with IBM Cloud Authentication, and is required for access to the watsonx.ai service.
- Region: Select the IBM Cloud region where watsonx.ai requests are sent.
- Operation version: Accept the default value or provide the appropriate Active Version Date of the watsonx.ai API, using the format **`yyyy-mm-dd`**.
  To see the available version dates, refer to Active Version Dates in the watsonx.ai API documentation. For information on API versioning in watsonx.ai, see Versioning in the same documentation.

8. Provide information about how the API accesses watsonx.ai to submit requests:
   - Exposed paths: Accept the default list of exposed paths, or select only the paths that you want your API to access. The exposed paths define which watsonx.ai operations are included in the generated API.
   - Enable response caching: Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. If you use response caching, you can specify the duration of the cache in the Cache TTL in seconds field.
     When response caching is enabled, then when a request is sent to the watsonx.ai service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that response and its associated HTTP response headers are placed into the DataPower API Gateway context message (which by default is named **`message`**). The Output Message property in the policy UI can be modified after the API has been generated if a different message is needed.

     If there is no cached response, the request is passed to the watsonx.ai service, and the response is cached for subsequent operations using the time-to-live specified in the Cache TTL in seconds property.

     Cache TTL in seconds: If you enable response caching, configure the duration of the cache by accepting the default value or selecting (or typing) a new value. The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.
9. In the Rate Limiting section, optionally configure rate limiting, and then click Next:
   a. Select Create product if you want to generate an API Connect product that controls rate limiting for the API.
      In API Connect, a product serves as a container for an API and its associated usage plans, which define rate limits. Setting the product rate limits here creates a plan that contains the required **`watson-ai-default`** and **`watson-ai-infer-text`** assembly rate limits and specifies the limits that you defined.

      If you choose not to generate a product automatically, you must create one as explained in Creating a custom product for a watsonx.ai API.

      Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. Either create the product now, or create a custom product before you publish the API.
   b. Configure the types of rate limiting to enforce on API calls:
      Note: If you choose not to specify the values of a rate limit, then default values for that rate limit will be assigned.
      - Set rate limit : (Time based) Accept the default rate limit or configure a new limit based on the number of API requests sent within a specified period of time. This type of rate limit does not use tokens.
      - Set AI token limit : (Token based) Accept the default rate limit or configure a new limit based on the number of cost-based tokens used within a specified period of time. Token-based rate limiting uses the **`/text-generate`** operation to track token usage.
        The AI token limit applies rate limiting based on the token usage. The rate limit determines how many tokens are allowed to pass thru the gateway within a specified period of time.
10. Review the Summary page to verify that the API has no issues, and then click Done.
11. Edit the new API and add policies and logic constructs that control the API's workflow.
    The created API will contain the watsonx.ai invoke policies for the exposed paths that were requested. Their properties can be edited as needed.

- **Creating a custom product for a watsonx.ai API**
  Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Creating a custom product for a watsonx.ai API

Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. If you did not select Create product to generate a product while creating the watsonx.ai API, you must create a custom product before you can publish the new API.
Create the product as explained in Creating a draft Product. In the product definition, add a plan with the **`watson-ai-default`** and **`watson-ai-infer-text`** assembly rate limits, as shown in the following example:

```
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/1hour
    assembly-rate-limits:
      watson-ai-default:
        - value: 200/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: '1'
      watson-ai-infer-text:
```

```
        - value: 200/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: aiGeneratedTokenCount
```

The watsonx.ai assembly rate limits are required
: The product must include a plan with the **watson-ai-default** and **watson-ai-infer-text** assembly rate limits, even if you add other plans to the product. You can configure the rate limits as needed for your own requirements.

Token-based rate limiting requires a token count
: The **weight: aiGeneratedTokenCount** property is required in the **watson-ai-infer-text** assembly rate limit. This variable indicates the number of tokens that will be added to the counter with each API call, and then compared with the rate limit threshold.

Rate limiting can apply to the catalog or to individual client IDs.
: Rate limiting is configured for the catalog that contains the API. By default, each client ID that subscribes to the plan within a particular catalog is assigned its own rate limit threshold. To configure a single threshold for the entire catalog, set **use-client-id: false** for that rate limit.

Creating a REST proxy for OpenAI with the AI Gateway

Create a REST proxy that uses the AI Gateway to control access to AI models.

Before you begin

Complete the tasks in Prerequisites for using the AI Gateway to ensure that you can access OpenAI.

About this task

The AI Gateway is only supported with OpenAPI 3.0 APIs.

Procedure

1. In the navigation pane, click  .
2. On the Develop page, click Add > API.
3. On the Select API type page, click the OpenAPI 3.0 tab.
4. In the Create section, select AI gateway, then click Next.
5. On the Create API from AI gateway page, use the Platform field to select openai as the AI service that the new API will use.
6. Use the "Info" section to provide basic information about the API, and then click Next:
   - The OpenAPI version is based upon the step 3 selection where you clicked on OpenAPI 3.0
   - Title: The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is filled in for you based on the title. The value is a single string that is used to identify the API in developer toolkit CLI commands.
   - Version: Accept the default value or modify it as needed. The version corresponds to the value of the **info.version** property of the OpenAPI definition. The **version.release.modification** version numbering scheme is recommended; for example `1.0.0`.
   - Base path: Accept the default value or modify it as needed. The API's "base path" is the server URL, which is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, you only need to provide the base path value. In addition:
     - Do not include the host name or any additional segments for paths or operations
     - Do not include special characters
     - Begin the URL with a forward slash (/) even if it is otherwise empty
   - Description: The optional description helps to identify the API.
7. Provide information about how the API accesses OpenAI to submit requests, and then click Create:
   - Project ID: Provide either the ID of the OpenAI project used for resolving API requests, or a $(name of a catalog property) whose value is the ID of the OpenAI project.
   - API key: Provide either the API key value, or the $(name of a catalog property) variable whose value is the API key.
     The API key allows the API to authenticate with OpenAI server, and is required for access to the OpenAI service.
   - Exposed paths: Accept the default list of exposed paths, or select only the paths that you want your API to access. The exposed paths define which OpenAI operations are included in the generated API.
   - Enable response caching: Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. If you use response caching, you can specify the duration of the cache in the Cache TTL in seconds field.
     When response caching is enabled, then when a request is sent to the OpenAI service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that response and its associated HTTP response headers are placed into the DataPower API Gateway context message (which by default is named **message**). The Output Message property in the policy UI can be modified after the API has been generated if a different message is needed.

If there is no cached response, the request is passed to the OpenAI service, and the response is cached for subsequent operations using the time-to-live specified in the Cache TTL in seconds property.

Cache TTL in seconds: If you enable response caching, configure the duration of the cache by accepting the default value or selecting (or typing) a new value. The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.

- In the **Rate Limiting** section, select **Create product** if you want to generate an API Connect product that controls rate limiting for the API.
  In API Connect, a product serves as a container for an API and its associated usage plans, which define rate limits. Setting the product rate limits here creates a plan that contains the required **`openai-default`** and **`openai-token-weighted`** assembly rate limits and specifies the limits that you defined.

  If you choose not to generate a product automatically, you must create one as explained in Creating a custom product for an OpenAI API.

  Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. Either create the product now, or create a custom product before you publish the API.
  Configure the types of rate limiting to enforce on API calls:

  Note: If you choose not to specify the values of a rate limit, then default values for that rate limit will be assigned.
  - Set rate limit : (Time based) Accept the default rate limit or configure a new limit based on the number of API requests sent within a specified period of time. This type of rate limit does not use tokens.
  - Set AI token limit : (Token based) Accept the default rate limit or configure a new limit based on the number of cost-based tokens used within a specified period of time. Token-based rate limiting uses the **`/chat/completions`** operation to track token usage.
    The AI token limit applies rate limiting based on the token usage. The rate limit determines how many tokens are allowed to pass thru the gateway within a specified period of time.

8. Review the Summary page to verify that the API has no issues.
9. Edit the new API and add policies and logic constructs that control the API's workflow.
   The created API will contain the OpenAI invoke policies for the exposed paths that were requested. Their properties can be edited as needed.

- **Creating a custom product for an OpenAI API**
  Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Creating a custom product for an OpenAI API

Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. If you did not select Create product to generate a product while creating the OpenAI API, you must create a custom product before you can publish the new API.
Create the product as explained in Creating a draft Product. In the product definition, add a plan with the **`openai-default`** and **`openai-token-weighted`** assembly rate limits, as shown in the following example:

```
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/1minute
    assembly-rate-limits:
      openai-default:
        - value: 100/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: '1'
      openai-token-weighted:
        - value: 200/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: aiGeneratedTokenCount
```

The OpenAI assembly rate limits are required
: The product must include a plan with the **`openai-default`** and **`openai-token-weighted`** assembly rate limits, even if you add other plans to the product. You can configure the rate limits as needed for your own requirements.

Token-based rate limiting requires a token count
: The **`weight: aiGeneratedTokenCount`** property is required in the **`openai-token-weighted`** assembly rate limit. This variable indicates the number of tokens that will be added to the counter with each API call, and then compared with the rate limit threshold.

Rate limiting can apply to the catalog or to individual client IDs.
: Rate limiting is configured for the catalog that contains the API. By default, each client ID that subscribes to the plan within a particular catalog is assigned its own rate limit threshold. To configure a single threshold for the entire catalog, set **`use-client-id: false`** for that rate limit.

Creating a REST proxy for Gemini with the AI Gateway

Create a REST proxy that uses the AI Gateway to control access to AI models.

Before you begin

Complete the tasks in Prerequisites for using the AI Gateway to ensure that you can access Gemini.

About this task

The AI Gateway is only supported with OpenAPI 3.0 APIs.

Procedure

1. In the navigation pane, click  .
2. On the Develop page, click Add > API.
3. On the Select API type page, click the OpenAPI 3.0 tab.
4. In the Create section, select AI gateway, then click Next.
5. On the Create API from AI gateway page, use the Platform field to select gemini as the AI service that the new API will use.
6. Use the "Info" section to provide basic information about the API, and then click Next:
   - The OpenAPI version is based upon the step 3 selection where you clicked on OpenAPI 3.0
   - Title: The Title can include special characters but should be kept short so that it can be easily displayed in the user interface.
   - The Name is filled in for you based on the title. The value is a single string that is used to identify the API in developer toolkit CLI commands.
   - Version: Accept the default value or modify it as needed. The version corresponds to the value of the `info.version` property of the OpenAPI definition. The `version.release.modification` version numbering scheme is recommended; for example `1.0.0`.
   - Base path: Accept the default value or modify it as needed. The API's "base path" is the server URL, which is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, you only need to provide the base path value. In addition:
     - Do not include the host name or any additional segments for paths or operations
     - Do not include special characters
     - Begin the URL with a forward slash (/) even if it is otherwise empty
   - Description: The optional description helps to identify the API.
7. Provide information about how the API accesses Gemini to submit requests, and then click Create:
   - API key: Provide either the API key value, or the $(name of a catalog property) variable whose value is the API key.
     The API key allows the API to authenticate with Google Studio, and is required for access to the Gemini service.
   - Exposed paths: Accept the default list of exposed paths, or select only the paths that you want your API to access. The exposed paths define which Gemini operations are included in the generated API.
   - Enable response caching: Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. If you use response caching, you can specify the duration of the cache in the Cache TTL in seconds field.
     When response caching is enabled, then when a request is sent to the Gemini service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that response and its associated HTTP response headers are placed into the DataPower API Gateway context message (which by default is named `message`). The Output Message property in the policy UI can be modified after the API has been generated if a different message is needed.

     If there is no cached response, the request is passed to the Gemini service, and the response is cached for subsequent operations using the time-to-live specified in the Cache TTL in seconds property.

     Cache TTL in seconds: If you enable response caching, configure the duration of the cache by accepting the default value or selecting (or typing) a new value. The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.
   - In the **Rate Limiting** section, select **Create product** if you want to generate an API Connect product that controls rate limiting for the API.
     In API Connect, a product serves as a container for an API and its associated usage plans, which define rate limits. Setting the product rate limits here creates a plan that contains the required `gemini-default` and `gemini-token-weighted` assembly rate limits and specifies the limits that you defined.

     If you choose not to generate a product automatically, you must create one as explained in Creating a REST proxy for Gemini with the AI Gateway.

     Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. Either create the product now, or create a custom product before you publish the API.
     Configure the types of rate limiting to enforce on API calls:

     Note: If you choose not to specify the values of a rate limit, then default values for that rate limit will be assigned.
     - Set rate limit : (Time based) Accept the default rate limit or configure a new limit based on the number of API requests sent within a specified period of time. This type of rate limit does not use tokens.
     - Set AI token limit : (Token based) Accept the default rate limit or configure a new limit based on the number of cost-based tokens used within a specified period of time. Token-based rate limiting uses the `/chat/completions` operation to track token usage.
       The AI token limit applies rate limiting based on the token usage. The rate limit determines how many tokens are allowed to pass thru the gateway within a specified period of time.
8. Review the Summary page to verify that the API has no issues.
9. Edit the new API and add policies and logic constructs that control the API's workflow.

The created API will contain the Gemini invoke policies for the exposed paths that were requested. Their properties can be edited as needed.

- **Creating a custom product for a Gemini API**
  Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Creating a custom product for a Gemini API

Create a product for an AI Gateway API and add a plan that contains the required assembly rate limits.

Attention: A product that is created later with the auto-publish feature (when publishing your API) does not include the required plan for using the AI service. If you did not select Create product to generate a product while creating the OpenAI API, you must create a custom product before you can publish the new API.
Create the product as explained in Creating a draft Product. In the product definition, add a plan with the **`gemini-default`** and **`gemini-token-weighted`** assembly rate limits, as shown in the following example:

```
plans:
  default-plan:
    title: Default Plan
    description: Default Plan
    approval: false
    rate-limits:
      default:
        value: 100/1minute
    assembly-rate-limits:
      gemini-default:
        - value: 100/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: '1'
      gemini-token-weighted:
        - value: 200/1minute
          hard-limit: true
          cache-only: false
          is-client: true
          use-api-name: false
          use-app-id: false
          use-client-id: true
          weight: aiGeneratedTokenCount
```

The Gemini assembly rate limits are required
: The product must include a plan with the **`gemini-default`** and **`gemini-token-weighted`** assembly rate limits, even if you add other plans to the product. You can configure the rate limits as needed for your own requirements.

Token-based rate limiting requires a token count
: The **`weight: aiGeneratedTokenCount`** property is required in the **`gemini-token-weighted`** assembly rate limit. This variable indicates the number of tokens that will be added to the counter with each API call, and then compared with the rate limit threshold.

Rate limiting can apply to the catalog or to individual client IDs.
: Rate limiting is configured for the catalog that contains the API. By default, each client ID that subscribes to the plan within a particular catalog is assigned its own rate limit threshold. To configure a single threshold for the entire catalog, set **`use-client-id: false`** for that rate limit.

Editing an OpenAPI 2.0 API definition

IBM® API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 2.0 specification.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

You can open an API for editing in either of the following ways:

- During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
- To open an existing API for editing, complete the following steps:
  1. In the navigation pane, click  Develop, then select the APIs tab.
  2. Click the title of the API version that you want to work with.

- **Specifying API metadata**
  API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.
- **Specifying the host for an API**
  You specify a host for an API if you want external developers on the portal to access your APIs by using a host address that is not the same as the API endpoints that are defined for the gateway services where your API will run.
- **Specifying the basepath for an API**
  The base path is the initial URL segment of the API, and does not include the host name or any additional segments for paths or operations. It is shared by all

operations in the API.

- **Specifying the schemes for an API**
  Schemes define which transfer protocols you want your API to use.
- **Specifying the MIME types that an API consumes**
  You can specify which types of media your API will accept when calls are made to it. The API Connect gateway supports XML and JSON.
- **Specifying the MIME types that an API produces**
  You can specify which types of media your API will return when calls are made to it. The API Connect gateway supports XML and JSON.
- **Enforcing security requirements on an API**
  To enforce security requirements on an API, you apply previously created security schemes that specify various aspects of API security configuration.
- **Specifying external documentation for an API**
  You can reference an external resource for extended documentation for an API.
- **Adding tags to an API**
  You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Defining Paths for an API**
  A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.
- **Defining schema definitions for an API**
  Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.
- **Defining parameters for an API**
  Parameters can specify variable elements of a URL path, query parameters, headers, or a request body.
- **Defining responses for an API**
  Responses define the HTTP status code and data returned in a response body and headers. Responses defined for an API can be used across operations.
- **Specifying gateway and portal settings**
  Define general configuration settings for your API.
- **Defining target services for an API**
  A target service defines a web service that you want to use in your API definition.
- **Setting API properties**
  In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.
- **Configuring application authentication for an API**
  Using this topic, you can configure application authentication for an API.
- **Configuring activity logging**
  You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.
- **Configuring v5 compatibility options**
  You can configure settings to ensure compatibility with API Connect Version 5.0 compatible APIs that are converted for use with the DataPower API Gateway.
- **Including elements in your API assembly**
  An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.
- **Specifying the gateway type for an API definition**
  An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). A default gateway type is set when you create an API definition, but you can edit the API configuration to specify a different gateway type.
- **Converting an API definition for deployment to the DataPower API Gateway**
  IBM API Connect provides two gateway types, DataPower Gateway (v5 compatible) and DataPower API Gateway. If you have an API definition that was developed for the DataPower Gateway (v5 compatible) and you want to port it to the DataPower API Gateway, you must make changes to convert it before deployment.
- **Modifying a GraphQL schema**
  For a GraphQL API, an editor is provided for modifying the associated GraphQL schema.
- **Validating the OpenAPI YAML source**
  How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.
- **Validating an API or product document by using the governance service**
  How to use governance rulesets to validate and enforce organizational governance policies and best practices. You can run validation scans on API and product documents from the API Manager UI, the API Designer UI, or the toolkit CLI.

Specifying API metadata

API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click Info.
3. Provide the following information:
   - Title (required): The title of the API.
   - Name: The name was generated automatically when the API was created and cannot be changed. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - Version: The API version is specified when the API is initially created and cannot be changed thereafter. You can, however, create a new version of an existing API; see Creating a new version of an API definition.
   - Description: An optional description of the API. You can use CommonMark syntax for rich text representation.

- Terms of Service: A URL to the Terms of Service for the API.
- Contact Name: The identifying name of the contact person/organization.
- Contact Url: A URL pointing to the contact information.
- Contact Email: The email address of the contact person/organization.
- License Name: The license name used for the API.
- License Url: A URL to the license used for the API.

4. Click Save when done.

Specifying the host for an API

You specify a host for an API if you want external developers on the portal to access your APIs by using a host address that is not the same as the API endpoints that are defined for the gateway services where your API will run.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click Host.
3. Enter the required host name.
   Note: To enable this capability, you must additionally configure API vanity endpoints in the Catalog Settings for the Catalog to which the API is published. For information on configuring vanity endpoints, see Creating and configuring Catalogs
4. Click Save when done.

Specifying the basepath for an API

The base path is the initial URL segment of the API, and does not include the host name or any additional segments for paths or operations. It is shared by all operations in the API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click Base Path.
3. Enter the required base path, preceded by a forward slash character (/).
4. Click Save when done.

Specifying the schemes for an API

Schemes define which transfer protocols you want your API to use.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section then, if there are already one or more schemes defined, expand Schemes List.
3. To specify a new scheme, click the add icon ⊕ alongside Schemes List. To modify an existing scheme, click the scheme entry in the navigation pane.

4. Select the required scheme from the list provided, then click Create.
5. Click Save when done.

Specifying the MIME types that an API consumes

You can specify which types of media your API will accept when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section then, if there are already one or more consumes MIME types defined, expand Consumes.
3. To specify a new MIME type, click the add icon ⊕ alongside Consumes. To modify an existing MIME type, click the MIME type entry in the navigation pane.
4. Enter the required value in the Mime Type field; for example, **`application/json`** or **`application/xml`**. Then click Create.
5. Click Save when done.

Specifying the MIME types that an API produces

You can specify which types of media your API will return when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section then, if there are already one or more produces MIME types defined, expand Produces.
3. To specify a new MIME type, click the add icon ⊕ alongside Produces. To modify an existing MIME type, click the MIME type entry in the navigation pane.
4. Enter the required value in the Mime Type field; for example **`application/json`** or **`application/xml`**. Then click Create.
5. Click Save when done.

Enforcing security requirements on an API

To enforce security requirements on an API, you apply previously created security schemes that specify various aspects of API security configuration.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme definitions, see Defining security schemes.

The following restrictions exist when you apply security schemes to an API:

- You cannot apply more than two API key security schemes to an API.
- If you apply an API key security scheme for client secret, you must also apply an API key security scheme for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security schemes.
- You can have at most one API key scheme of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key scheme of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- You cannot apply more than one basic security scheme to an API. If you apply a basic security scheme, you cannot also apply an OAuth security scheme.
- You can apply at most one OAuth security scheme to an API.

A security requirement specifies one or more security schemes whose conditions must all be satisfied for the API to be called successfully. You can define multiple security requirements; in this case, an application can call your API if it satisfies any of the security requirements you have defined.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand General.
3. To create a new security requirement for the API, complete the following steps:
   a. Click the add icon alongside Security in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined; see Defining security schemes.
   If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme; for more information, see Defining OAuth2 security schemes.

   If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower® API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

   Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Submit when done.
4. To modify an existing security requirement, complete the following steps:
   a. Click Security in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
   c. Click Submit when done, then click Save.
   d. To delete a security requirement, click the appropriate delete icon, click Delete to confirm, then click Save.
   e. To disable security for the API, clear the Require one of the following Security Requirements check box, then click Save.

- **Defining security schemes**
  A security scheme specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.
- **Enabling CORS support for an API**
  You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Defining security schemes

A security scheme specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create security definitions of the following types:

Type	Description
Basic authentication	Use a basic authentication security definition to specify a user registry or an authentication URL to be used to authenticate access to the API.
API key	Use an API key security definition to specify what application credentials are required to call an API.
OAuth2	Use an OAuth2 security definition to specify settings for OAuth token based authentication for your API.

- **Defining basic authentication security schemes**
  A basic authentication security scheme is used when an application that calls the API is required to authenticate through a user registry.
- **Defining API key security schemes**
  An API key security scheme is used to specify the credentials that an application must provide to identify itself when calling the API operations.
- **Defining OAuth2 security schemes**
  An OAuth2 security scheme defines the settings for controlling access to the API operations through the OAuth authorization standard.

Defining basic authentication security schemes

A basic authentication security scheme is used when an application that calls the API is required to authenticate through a user registry.

Before you begin

For authenticating access to the operations of APIs that are enforced on the API Connect gateway, the following user registry types are supported:

- Authentication URL
- LDAP

The following user registry types are **not** supported:

- OpenID Connect (OIDC)
- Local User Registry (LUR)
- A custom user registry

Before you can create a basic authentication security definition in an API, the user registry must exist. To create a user registry, you can use either API Manager or Cloud Manager. When you create a registry in API Manager, it is visible only to your provider organization. When you create a registry in Cloud Manager, you can make it visible to

multiple provider organizations.

To create a user registry with API Manager, see Working with user registries.

To create a user registry with Cloud Manager, see User registries overview.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you use basic authentication, you require API users to provide a valid user name and password to access selected operations. The application developer must also provide an HTTP authorization header in requests that are sent to operations that require basic authentication.

When you use an authentication URL, the user credentials that are provided in the authorization header are validated by the endpoint specified in the URL. If the user is authenticated, IBM® API Connect expects an authentication URL to return an HTTP `200 OK` response status code. All other HTTP response status codes result in an authentication failure and access is denied.

For more information about using an LDAP user registry for authentication, see LDAP authentication.

For information about using an Authentication URL, see Authentication URL user registry.

To make use of a basic authentication security scheme, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create a basic authentication security scheme, click the add icon ⊕ alongside Security Schemes, then select basic for the Security Definition Type. To edit an existing basic authentication security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Name field.
5. Select the user registry from the Authenticate using User Registry list.
   The user registries in the list are those that have been enabled in the Sandbox Catalog; for details, see Creating and configuring Catalogs.
6. Optionally, provide a Description for the security scheme. You can use CommonMark syntax for rich text representation.
7. If you are creating a new basic authentication security scheme, click Create.
   The security scheme details are displayed for further editing.
8. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

For more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

Defining API key security schemes

An API key security scheme is used to specify the credentials that an application must provide to identify itself when calling the API operations.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can require that, when calling an API operation, an application must provide either a client ID, or a client ID and client secret; you create an API key security scheme to specify a credentials requirement. If you require that an application must provide both a client ID and client secret, you must create two API key security schemes, one for each type of credentials.

To make use of an API key security scheme, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create an API key security scheme, click the add icon ⊕ alongside Security Schemes, then select apiKey for the Security Definition Type. To edit an API key existing security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Security Scheme Name field.
5. Specify the parameter name in the Name field.

If your API is not enforced by the API Connect gateway, enter the parameter name required by your gateway.

If your API is enforced by the IBM® API Connect gateway, the required value depends on the gateway type setting for the API, as follows:

- DataPower® API Gateway: For a key of type client secret, you must include the string "secret", ignoring case, in the value you specify in the Name field; if the value does not contain the string "secret" then the key is assumed to be of type client ID.
- DataPower Gateway (v5 compatible): the value must be as specified in the following table, depending on where the client credentials are located, and the type of credentials.

Table 1. Client ID and Client secret parameter name values for the DataPower Gateway (v5 compatible)

Location of credentials	Type of credentials	Parameter name
Header	Client ID	X-IBM-Client-Id
Header	Client secret	X-IBM-Client-Secret
Query	Client ID	client_id
Query	Client secret	client_secret

When you first create an API, a default API key security definition, of type client ID, is provided.

For information about including API key parameters in an API call, see Calling an API.

Note:

- You cannot apply more than two API key security definitions to an API.
- If you apply an API key security definition for client secret, you must also apply an API key security definition for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security definitions.
- You can have at most one API key definition of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key definition of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- The client ID and client secret headers that are specified in the request when the API is called are **not** added automatically to the message context. If you need these headers in the message context for subsequent processing, include a `set-variable` policy in your API assembly that adds the headers to the message content, taking the values specified in the request; you can do this in either of the following ways:
  - In the Assemble tab, add a Set Variable policy to your API assembly that defines the appropriate actions; for example:

Table 2.

Action	Set	Type	Value
Set	message.headers.X-IBM-Client-Id	string	$(request.headers.X-IBM-Client-Id)
Set	message.headers.X-IBM-Client-Secret	string	$(request.headers.X-IBM-Client-Secret)

For more information on configuring a Set Variable policy, see Set Variable.

  - In the Source tab, add a `set-variable` policy directly to the assembly section in your OpenAPI source; for example:

```
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-IBM-Client-Id
            value: $(request.headers.X-IBM-Client-Id)
            type: string
          - set: message.headers.X-IBM-Client-Secret
            value: $(request.headers.X-IBM-Client-Secret)
            type: string
```

For more information on defining a `set-variable` policy in your OpenAPI source, see set-variable.

You should position the `set-variable` before any policy that needs to access the API key headers; for example, an invoke policy that calls a back-end service that is required to identify the application that made the initial request.

6. Select the Key Type: client_id or client_secret.
   Important: The client_id is not confidential and functions as a "SecurityScheme" only in the meaning of the OpenAPI specification.
   If you use only the client_id (without the client_secret) as your API Key, be aware that the client_id is not considered a confidential value in the API Manager UI; for example, it might be displayed to other authenticated members of the provider organization. The client_id is treated as a public identifier for apps and cannot be kept private.

   If authentication of the identity of the app calling an API is needed, then the API Key should use both a client_id to identify the app, plus a client_secret to authenticate it. The client_secret is designed to be known only to the app and the authorization server, and it should be protected. IBM API Connect protects the client_secret: it is only available when first generated, it can be stored as a one-way hash to prevent retrieval or leaks, and it can be changed and reset without changing the corresponding client_id. When an API Key is not marked as a client_secret, it will not be protected in the API Manager UI.

7. Specify whether the credentials are sent in the request header, or as query parameters, by selecting one of the following Located In options:

   header
   : The credentials are sent in the request header. This is the default setting.

   query
   : The credentials are sent as query parameters. This method is less secure because the client secret could be exposed in a log file.

   The selected option is enforced, and API calls fail if the credentials are included in the wrong location by the caller.

   Note:

   - You must specify the same location for the client ID and client secret, either header or query.
   - If you migrated from API Connect V5, API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. For information about the differences, see Client ID behavior in API key security definitions.

8. Optionally, provide a Description for the security scheme. You can use CommonMark syntax for rich text representation.
9. If you are creating a new API key security scheme, click Create.
   The security scheme details are displayed for further editing.
10. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

- **Client ID behavior in API key security definitions**
  How the Client ID behaves in API key security definitions in IBM API Connect 10 compared to Version 5.

Client ID behavior in API key security definitions

How the Client ID behaves in API key security definitions in IBM® API Connect 10 compared to Version 5.

API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. Refer to the following table to understand the differences in Client ID behavior for different use cases.
Note: Although a client_id in the request body is supported, this data is not used during security requirement processing.

Table 1. Client ID behavior in V5 and V10

Use case	Description of security requirement	V5 behavior	V10 behavior
1	Allows client_id in the query, and the request contains multiple client_ids in the query.	Uses the first client ID in the request.	401 invalid client ID or secret.
2	Allows client_id in the header, and the request contains multiple client_ids in the header.	401 invalid client ID or secret.	401 invalid client ID or secret.
3	Allows client_id in the header, and the request contains multiple client_ids in the query and the header (1 in the query, 1 in the header).	401 client ID in wrong location.	Client ID in query is ignored.
4	Allows client_id in the query, and the request contains multiple client_ids in the query and the header.	Client ID in header is ignored.	Client ID in header is ignored.
5	Allows client_id in the query or header, and both the query and header contain multiple client_ids.	Header returns 401 client ID in wrong location. Query uses the first client ID in the request.	401 invalid client ID or secret.
6	Allows client_id in the header, and the request contains a valid client_id in the query, and an invalid client_id in the header.	401 client ID in wrong location.	401 invalid client ID or secret.
7	Allows client_id in the query, and the request contains a valid client_id in the header, and an invalid client_id in the query.	401 invalid client ID or secret.	401 invalid client ID or secret.
8	Allows client_id in the query or header, and both the query and header contain valid client_ids.	200 OK.	403 multiple client IDs.
9	Allows client_id in the query or header, and both the query and header contain invalid client_ids.	401 client ID in wrong location.	401 invalid client ID or secret.
10	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the query is valid.	200 OK.	Uses the valid one 200 OK.
11	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the header is valid.	401 client ID in wrong location.	Uses the valid one 200 OK.
12	Allows client_id in the query or header, and both the query and client_id is missing in the request (no security requirement, but client security is defined in the assembly).	401 invalid client ID or secret.	• When Return V5 Responses compatibility option is off: 401 client ID is missing. • When Return V5 Responses compatibility option is on: 401 invalid client ID or secret. For information about setting compatibility options, see Configuring v5 compatibility options.

Defining OAuth2 security schemes

An OAuth2 security scheme defines the settings for controlling access to the API operations through the OAuth authorization standard.

Before you begin

Before you can create an OAuth2 security scheme, you must:

1. Create an OAuth provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Add the OAuth provider to a catalog. If you have not created any catalogs, use the Sandbox Catalog. See the OAuth instructions step in Creating and configuring Catalogs.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an OAuth2 security scheme, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon. To return to the design form, click the Form icon.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. If there are already one or more security schemes defined, expand Security Schemes.
3. To create an OAuth2 security scheme, click the add icon alongside Security Schemes, then select oauth2. To edit an existing OAuth2 security scheme, click the security scheme name in the navigation pane.
4. Enter an identifying name of your choice in the Security Scheme Name field.
5. Provide the following information:
   - Security Scheme Name: An identifying name of your choice.
   - OAuth Provider: Select the OAuth provider to be used.
   - Flow: Select one of the following options:
     - Implicit
     - Resource Owner - Password
     - Application
     - Access Code

     Note: The flow options that are available for selection depend on which options are supported by the selected OAuth provider.
     If you selected Resource owner - JWT as the supported grant type when you created the OAuth provider, you must select Resource owner - Password as the Flow for this security scheme.
   - Description: An optional description of the OAuth2 security scheme. You can use CommonMark syntax for rich text representation.
   - The URL endpoints (the applicable endpoints depend on the flow type):
     - Authorization Url
     - Token Url

     Note: The URL endpoint values supplied here are maintained only for informative purposes, no validation or other action is applied to them by API Connect. The OAuth security that is applied depends on the specified OAuth provider.
   - Scopes (available if you are editing an existing OAuth2 security scheme):
     - To add a new scope, click Add. To edit an existing scope, click the options icon alongside the required scope, then click Edit.
     - Provide the following information:
       - Scope: The scope identifier.
       - Description: An optional description of the scope. You can use CommonMark syntax for rich text representation.
       - If you are creating a new scope, click Create.
6. If you are creating a new OAuth2 security scheme, click Create.
   The security scheme details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Enabling CORS support for an API

You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Before you begin

This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.

About this task

Note:

- CORS support is available only on the DataPower® API Gateway.
- When CORS is enabled, the API Gateway runs the `cors` preflow policy to handle all CORS requests that are made to the API.
- When CORS is enabled and a preflight request is received, only the following API actions are performed:
  - The `cors` preflow policy configures the appropriate response headers.
  - The response headers are set.
- When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.
- For all preflight requests, the `security` and `client-identification` preflow policies are always skipped, whether CORS is enabled or not enabled.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon. To return to the design form, click the Form icon.

Procedure

To enable CORS support for an API, complete the following steps:

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.

2. Select the Gateway tab, expand Gateway and portal settings, then click CORS.
   The CORS page opens.
3. Select Enabled.
4. Optional: Configure a CORS policy.
   Should you create a CORS policy? Review the following considerations:
   - A CORS policy is an optional part of an API definition. If an API definition has no CORS policy but CORS is enabled, then CORS requests will be accepted from all Origins.
     If you want to accept CORS requests from all Origins, then enable CORS but do not add a CORS policy to the API definition.
   - If you create a CORS policy, then CORS requests will only be accepted from Origins that are explicitly listed in the CORS rules contained in the CORS policy. CORS requests from any other Origins will be rejected.
     If you want to accept CORS requests from only a limited number of Origins (and might also want to configure the Access-Control-Allow-Credentials and Access-Control-Expose-Headers response headers), then you should enable CORS and create a CORS policy. Only those Origins explicitly listed in the allow-origin field of the CORS rules in the CORS policy will be accepted; CORS requests from any Origins not listed will be rejected.
   - To configure a new CORS policy, complete the following steps:
     - Alongside Policy, click Add.
     - To include the header `Access-Control-Allow-Credentials: true` in a response. select Allow Credentials. The `Access-Control-Allow-Credentials` response header tells browsers whether to expose the response to front-end JavaScript code when the request's credentials mode (`Request.credentials`) is set to `include`.
     - To append one or more of the following values to the `Access-Control-Expose-Headers` response header, select Expose headers, and select from the following options:
       - Predefined - The predefined value of the Gateway. This option is selected by default.
       - Backend - The value of `Access-Control-Expose-Headers` from the backend response.
       - Custom - A custom string.
     - Click Create.
     - Alongside Allowed Origins click Add.
     - Enter the origin URL, then click Create. This setting indicates that the response can be shared with requesting code from the specified origin.
   - To modify an existing CORS policy, click its entry on the CORS page. You can then modify individual origin URLs, add further origins, and change the Allow Credentials setting.

   Example

   The following example has three rules:
   - Accept an Origin header of `https://example.com`, and return `Access-Control-Allow-Credentials: true` in the CORS response.
   - Accept an Origin header of `http://domain.com`. No `Access-Control-Allow-Credentials` header will be returned in the response.
   - Accept any of the following Origin headers:
     - `http://example2.com`
     - `http://example3.com`
     - `http://example4.com`

     No `Access-Control-Allow-Credentials` header will be returned in the response.

```
cors:
  enabled: true
  policy:
    -
      allow-origin:
        - 'https://example.com'
      allow-credentials: true
    -
      allow-origin:
        - 'http://domain.com'
    -
      allow-origin:
        - 'http://example2.com'
        - 'http://example3.com'
        - 'http://example4.com'
```

5. Click Save to save your changes.
6. Optional: To implement your own CORS solution using custom OPTIONS operations, complete the following steps:
   a. Add the following headers to your HTTP responses:

```
Access-Control-Allow-Origin: https://<portalhostname>
Access-Control-Allow-Headers: Origin, X-Requested-With, Content-Type, Accept
```

   Where `<portalhostname>` is your Developer Portal host name.
   b. Optional: You can proxy your API through API Connect as an enforced invoke API so that CORS is handled automatically.

   Important:
   - If you implement your own CORS solution, you **must** disable the CORS option described in step 3
   - CORS preflight requests are sent by using the HTTP `OPTIONS` method. Therefore, if you require these requests to be handled by the API Connect gateway then you must enable the `OPTIONS` method for all APIs that will handle preflight requests; see Defining Paths for a REST API.
   - `OPTIONS` requests are counted as API calls against any configured rate limit. Note that you can apply rate limits to individual operations; see Defining rate limits for an API operation.

Specifying external documentation for an API

You can reference an external resource for extended documentation for an API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General section, then click External Documentation.
3. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
4. Click Save when done.

Adding tags to an API

You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand the General then, if there already one or more tags defined, expand Tags.
3. To add a new tag, click the add icon ⊕ alongside Tags in the navigation pane. To edit an existing tag, click the tag name in the navigation pane.
4. Provide the following information:
   - Name (required): The name of the tag.
   - Description: An optional description of the tag. You can use CommonMark syntax for rich text representation.
   - External Documentation > URL (available when editing an existing tag): The URL for target documentation that describes this tag.
   - External Documentation > Description (available when editing an existing tag): An optional description of the target documentation.
5. If you are creating a new tag, click Create.
6. Click Save when done.

Defining Paths for an API

A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more Paths defined, expand Paths.
3. To create a new Path, click the add icon ⊕ alongside Paths in the navigation pane. To edit an existing Path, click the Path in the navigation pane.
4. Provide the following information:
   - Path: A relative path to an individual endpoint.
     The path is appended to the base path to construct the full URI to access the APIs. The path must start, but not end, with the / character. A parameter at the end of the path can contain a qualifier to match one or more path levels.

     If you specify just the name of the parameter, then one level of that path is matched. If you want to allow for multiple levels of the path, you can prefix the parameter with one of the following qualifiers:

     - * to indicate 0 or more occurrences
     - + to indicate 1 or more occurrences

     The + and * qualifiers can only be used at the end of the path.

     For example, the path:

     ```
     /petstore/{type}/{*category}
     ```

matches the following paths, where only one type value is matched, but all (0 or more) categories are matched:

```
/petstore/cats
/petstore/cats/supplies
/petstore/cats/supplies/health
/petstore/cats/supplies/health/medicines
/petstore/cats/supplies/health/medicines/a/b/c
```

- $ref (available when editing an existing Path): A reference to a Path that is defined elsewhere, either in this OpenAPI definition, or in an external file. A reference enables reuse of a set of operations already defined for a Path in this API, or in a file that is either a complete API definition or an OpenAPI fragment.
  The reference uses JSON pointer notation. For example, a reference to a Path called `/mypath` in this API would have the following format:

  ```
  #/paths/~1mypath
  ```

  The `~1` characters are used to escape the `/` character, which is being used literally in the path name rather than as a special character.
  A reference to a path in an external file called path_fragments.yaml would have the following format:

  ```
  file://path_fragments.yaml/paths/~1mypath
  ```

5. If you are creating a new Path, click Create.
   The Path details are displayed for further editing as described in step 4.
6. Click Save when done.

- **Defining parameters for a path**
  Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.
- **Defining operations for a path**
  Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

Defining parameters for a path

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there already one or more parameters defined, expand Path Parameters.
4. You can either create a new parameter, or edit any existing parameter.
   - To create a parameter, click the add icon ⊕ alongside Path Parameters, then refer to Creating a parameter.
   - To edit an existing parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining operations for a path

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required path.
3. Click the add icon ⊕ alongside Operations under the Path in the navigation pane.
4. Provide the following information:
   - Verb: Select the operation type from the following options:
     - get

        - post
        - put
        - delete
        - options
        - head
        - patch
        - trace
    - Summary: A summary of what the operation does.
    - Description: A description of the operation behavior.
    - Operation: Unique string used to identify the operation. The id must be unique among all operations described in the API.
    - Deprecated: Declares this operation to be deprecated. Consumers should refrain from using the declared operation.
5. Click Create.
6. Click Save when done.

- **Adding tags to an operation**
  You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Specifying external documentation for an operation**
  You can referencing an external resource for extended documentation for an API operation.
- **Specifying the MIME types that an API operation produces**
  You can specify which types of media your API operation will return when calls are made to it. The API Connect gateway supports XML and JSON.
- **Specifying the MIME types that an API operation consumes**
  You can specify which types of media your API operation will accept when calls are made to it. The API Connect gateway supports XML and JSON.
- **Defining parameters for an operation**
  Responses define the HTTP status code and data returned in a response body and headers.
- **Defining responses for an operation**
  Responses define the HTTP status code and data returned in a response body and headers. A response defined for an operation is one that can returned by executing the operation.
- **Specifying schemes for an operation**
  The schemes settings define which transfer protocols you want your API operation to use.
- **Enforcing security requirements on an operation**
  To enforce security requirements on an API operation, you apply previously created security schemes that specify various aspects of API security configuration.

Adding tags to an operation

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To add a new operation tag, click the add icon ⊕ alongside the Tags entry for the operation in the navigation pane. To edit an existing tag, expand Tags then click the tag name in the navigation pane.
5. Provide the following information:
    - Name (required): The name of the tag.
6. If you are creating a new operation tag, click Create.
7. Click Save when done.

Specifying external documentation for an operation

You can referencing an external resource for extended documentation for an API operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.

3. Expand Operations, expand the required operation, then click External Documentation.
4. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
5. Click Save when done.

Specifying the MIME types that an API operation produces

You can specify which types of media your API operation will return when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To specify a new MIME type, click the add icon ⊕ alongside Produces. To modify an existing MIME type, click the MIME type entry in the navigation pane.
5. Enter the required value in the Mime Type field; for example **`application/json`** or **`application/xml`**. Then click Create.
6. Click Save when done.

Specifying the MIME types that an API operation consumes

You can specify which types of media your API operation will accept when calls are made to it. The API Connect gateway supports XML and JSON.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To specify a new MIME type, click the add icon ⊕ alongside Consumes. To modify an existing MIME type, click the MIME type entry in the navigation pane.
5. Enter the required value in the Mime Type field; for example, **`application/json`** or **`application/xml`**. Then click Create.
6. Click Save when done.

Defining parameters for an operation

Responses define the HTTP status code and data returned in a response body and headers.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. You can either create a new operation parameter, or edit any existing parameter.
   - To create an operation parameter, click the add icon ⊕ alongside Path Parameters, then refer to Creating a parameter.

- To edit an existing operation parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining responses for an operation

Responses define the HTTP status code and data returned in a response body and headers. A response defined for an operation is one that can returned by executing the operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing responses, expand Responses.
4. You can either create a new response, or edit any existing response.
   - To create a response, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response, click the response name in the navigation pane, then refer to Editing a response.

Specifying schemes for an operation

The schemes settings define which transfer protocols you want your API operation to use.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing schemes, expand Schemes List.
4. You can either add a new scheme, or edit any existing scheme.
   - To add a scheme, click the add icon ⊕ alongside Schemes List, select the required transfer protocol, then click Create.
   - To edit an existing scheme, click the scheme in the navigation pane, then change the transfer protocol as required.
5. Click Save when done.

Enforcing security requirements on an operation

To enforce security requirements on an API operation, you apply previously created security schemes that specify various aspects of API security configuration.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security schemes, see Defining security schemes.

A security requirement specifies one or more security scheme definitions whose conditions must all be satisfied for the API operation to be called successfully. You can define multiple security requirements; in this case, an application can call your API operation if it satisfies any of the security requirements you have defined.

Any security requirements that you define for an operation completely override any security requirements defined on the parent API. If you do not define any security requirements for an operation, or you delete all security requirements from an operation, the operation inherits the security requirements defined on the parent API. For more information, see Enforcing security requirements on an API.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To create a new security requirement for the operation, complete the following steps:
   a. Click the add icon alongside the Security entry for the operation in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have previously been defined; see Defining security schemes.
   If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme; for more information, see Defining OAuth2 security schemes.

   If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower® API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

   Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Save when done.
5. To modify an existing security requirement, complete the following steps:
   a. Click the Security entry for the operation in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
   c. Click Submit when done, then click Save.
   d. To delete a security requirement, click the appropriate delete icon, click Delete to confirm, then click Save.
   e. To disable security for the operation, clear the Require one of the following Security Requirements check box, then click Save.

Note: These settings completely override any security requirements defined on the parent API; see Enforcing security requirements on an API.

Defining schema definitions for an API

Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
An API created in OpenAPI 2.0 includes a section where API payload definitions are defined. The payload definitions describe the structure of data transmitted in API requests and responses, utilizing a specialized JSON schema variant specific to OpenAPI. Each payload definition corresponds to a schema, which lists the expected data fields. These data fields are represented as properties within the schema and include a set of attributes that describe their type, permissible values, mandatory status, and other characteristics. Although numerous attributes are available, the majority of them are infrequently utilized.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there are already one or more schemas defined, expand Definitions.
3. You can create a new schema, or edit any existing schema.
   - To create a schema, click the add icon alongside Definitions, then refer to Creating schema definitions.
   - To edit an existing schema, click the schema component name in the navigation pane, then refer to Editing schema definitions.

- **Creating schema definitions**
  Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.
- **Editing schema definitions**
  Schemas provide developers with information about the request that they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Creating schema definitions

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.

For details of the areas in your API definition from where you can create a schema, see the following topics:

- Defining schema definitions for an API
- Editing a response

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. To create a schema definition, click the add icon ⊕ alongside Definitions.
   The Add object wizard for a schema is displayed.
2. Provide the following information:
   - Schema Name: This name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/definitions/Name`

   - Title: The schema title.
   - Type: The schema data type; select one of the following:
     - array
     - boolean
     - integer
     - number
     - object
     - string
3. Click Create.
   The schema definitions details are displayed for further editing; see Editing schema definitions.

Editing schema definitions

Schemas provide developers with information about the request that they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
For details of the areas in your API definition from where you can edit a schema, see the following topics:

- Defining schema definitions for an API
- Editing a response

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The table view presents the properties within a schema alongside their essential attributes, such as name, type, description, and required status. The secondary pop-up enables access for viewing and editing the more detailed and less commonly used attributes that are associated with each data field.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

You can configure the following schema definition settings:

- Schema Name: This name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/definitions/Name`

  To change the name, click the Source icon, change the value in the field, then click Save.
- Optional: Title: The schema title.
- Type: The schema data type; select one of the following:
  - array
  - boolean
  - integer
  - number

        - object
        - string

    Note: If you change the type of an existing schema, any existing settings that are not relevant to the new type are still retained in the OpenAPI source even though they are no longer displayed in the user interface. You should therefore avoid porting a schema from one type to another but instead either create a new schema or modify the OpenAPI source directly; to open the source editor, click the Source icon </> .
- Properties: The schema property. To add a property to the schema, click Add alongside the Properties section heading, complete the details and click Save.
- Additional schema settings dependent on the selected Type of property. To view and edit these schema settings, click the Options menu next to the property you want to view and select Details.
    - boolean: no type specific settings.
    - integer:
        - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
        - Multiple Of: Division of an integer instance by this value must result in an integer.
        - Maximum: An integer instance must be less than or equal to this value.
        - Exclusive Maximum: An integer instance must be strictly less than this value.
        - Minimum: An integer instance must be greater than or equal to this value.
        - Exclusive Minimum: An integer instance must be strictly greater than this value.
    - number:
        - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
        - Multiple Of: Division of a number instance by this value must result in an integer.
        - Maximum: A number instance must be less than or equal to this value.
        - Exclusive Maximum: A number instance must be strictly less than this value.
        - Minimum: A number instance must be greater than or equal to this value.
        - Exclusive Minimum: A number instance must be strictly greater than this value.
    - object:
        - Max Properties: The number of properties in an object instance must be less than or equal to this value.
        - Min Properties: The number of properties in an object instance must be greater than or equal to this value.
        - Required Properties: An array of property names; every property name in the array must be the name of a property in an object instance. To add a required property name, click Add alongside the Required Properties section heading, enter the name, then click Create.
    - string:
        - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
        - Pattern: A regular expression; a string instance must successfully match the expression.
        - Max Length: The maximum allowed number of characters in a string instance.
        - Min Length: The minimum allowed number of characters in a string instance.
        - Enum: An array of string values; a string instance must match one of the array values. To add an enum value, click Add, enter the value, then click Create.
- General settings; select the required options:
    - Required: A property associated with this schema is required.
    - Read Only: A property associated with this schema can be returned in a response but should not be included in a request. For example, properties whose values are system generated identifiers will be defined as Read Only because application clients wouldn't be able to set these.
- Example Value: An example value. Whatever you enter here is displayed as-is in the Developer Portal.
- External Documentation: An external resource for extended documentation; provide the following information:
    - URL (required): The URL for the target documentation.
    - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
- Xml: Metadata that allows for more fine-tuned XML model definitions; provide the following information:
    - Name: Replaces the name of the element or attribute that is used for the described schema property.
    - Namespace: The URL of the namespace definition.
    - Prefix: The prefix to be used for the Name.
    - Attribute: Specifies whether the property definition translates to an attribute instead of an element.
    - Wrapped: For an array definition, Specifies whether the array is wrapped (for example, `<books><book/><book/></books>`) or unwrapped (`<book/> <book/>`).
- Click Save when done.

Example

By defining properties, you can create more complex data structures. For example, you could define an "Address" schema that has the following properties:

PROPERTY NAME	PROPERTY TYPE
street1	string
street2	string
city	string
state	string
zip_code	string

and then define a "BankBranch" schema that has the following properties, one of which is a reference to the Address schema:

PROPERTY NAME	PROPERTY TYPE
address	address
type	string
id	string

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining parameters for an API

Parameters can specify variable elements of a URL path, query parameters, headers, or a request body.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there already one or more parameters defined, expand Parameter Definitions.
3. You can either create a new parameter, or edit any existing parameter.
   - To create a parameter, click the add icon ⊕ alongside Parameters, then refer to Creating a parameter.
   - To edit an existing parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

- **Creating a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.
- **Editing a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for the API, or for Paths and Path operations in your API definition.

Creating a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

Before you begin

Launch the parameter creation window. For details of the areas in your API definition from where you can create a parameter, see the following topics:

- Defining parameters for a path
- Defining parameters for an operation
- Defining parameters for an API

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Parameter Name: The name of the parameter.
     Note: When the name of a query parameter includes the "+" special character, it is encoded as %2B (literal plus character) instead of %20 (literal space character). Therefore, to match the query parameter against the inbound URL, the encoded value is used. For example, when the name of the query parameter is a+space, the value to match in the inbound URL is a%2Bspace.
   - Located In: The location of the parameter. Select one of the following options:
     - query: Parameters that are appended to the URL. For example, ***`url_path`*`?myparam=myvalue`**.
     - header: Custom headers that are expected as part of the request.
     - path: The parameter value is part of the operation's URL, enclosed in {}.
     - body: Parameters that describe the body of POST, PUT and PATCH requests.
   - Description: A description of the parameter.
   - Type: The data type of the parameter.
   - Format: Select the data format; the available options depend on the selected Type.
   - Select the following option as required:
     - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
     - Allow Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
2. Click Create.
   The parameter details are displayed for further editing; see Editing a parameter.

Editing a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for the API, or for Paths and Path operations in your API definition.

Before you begin

Open the details form for a parameter. For details of the areas in your API definition from where you can edit a parameter, see the following topics:

- Defining parameters for a path
- Defining parameters for an operation
- Defining parameters for an API

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
   - Type: The data type of the parameter.
   - Format: Select the data format; the available options depend on the selected Type.
   - Select the following options as required:
     - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
     - Allow Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining responses for an API

Responses define the HTTP status code and data returned in a response body and headers. Responses defined for an API can be used across operations.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. If there already one or more responses defined, expand Response Definitions.
3. You can either create a new response, or edit any existing response.
   - To create a response, click the add icon ⊕ alongside Response Definitions, then refer to Creating a response.
   - To edit an existing response, click the response name in the navigation pane, then refer to Editing a response.

- **Creating a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.
- **Editing a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Creating a response

Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.

Before you begin

Launch the response creation window. For details of the areas in your API definition from where you can create a response, see the following topics:

- Defining responses for an API
- Defining responses for an operation

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The HTTP status code.
   - Description (required): A description of the response.
2. Click Create.
   The response details are displayed for further editing; see Editing a response.

Editing a response

Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Before you begin

Open the details form for a response. For details of the areas in your API definition from where you can edit a response, see the following topics:

- Defining responses for an API
- Defining responses for an operation

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The HTTP status code.
   - Description (required): A description of the response.
   - Schema: The schema defines the response structure.
     To define a schema for the response, click Create, then refer to Creating schema definitions.

     If the response already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing schema definitions.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Specifying gateway and portal settings

Define general configuration settings for your API.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, then click Gateway and portal settings.
3. Provide the following information:
   - Target Services: Define web services that you want to use in your API definition. For details, see Defining target services for an API.
   - Enforced: Select this option to enforce the API by using the DataPower® API Gateway. Clear this option if you are managing the API on a gateway other than the DataPower API Gateway. Although not published to a gateway by API Connect, an unenforced API is still available in the Developer Portal for subscription by application developers.
   - Phase: The phase of the lifecycle that your API is in; select one of the following options:
     - Realized (default) - The API is in the implementation phase.
     - Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
     - Specified - The API has been fully designed and passed an internal milestone but has not yet been implemented.
   - Testable: Select this option to allow the API's operations to be tested using the test tool in the Developer Portal.
     Note: For the test tool to work, an API must be included in a Plan in a Product that is staged in a Catalog.
   - CORS: Enable and configure cross-origin resource sharing (CORS) support for your API. For details, see Enabling CORS support for an API.
   - Properties: Add properties that can be referenced in your API definition. For details, see Setting API properties.
   - Catalog Properties: Define property values that are specific to a particular Catalog. For details, see Defining Catalog specific property values.
   - Gateway: For details, see Specifying the gateway type for an API definition.
   - Application Authentication: Enable application authentication to protect your API with a certificate. For details, see Configuring application authentication for an API.
   - Application Authentication Source: If application authentication is enabled, specify how the client certificate is sent to the gateway. For details, see Configuring application authentication for an API.
   - Activity Log: Configure your logging preferences for the API activity that is stored in analytics. For details, see Configuring activity logging.
   - Compatibility: For details, see Configuring v5 compatibility options.
   - Html Page: For a GraphQL API, the HTML page with which the API responds to an initial GraphiQL editor request. Currently, the only option is `store:///graphiql.html`. For more information, see Enabling the GraphiQL editor for a GraphQL API.
   - Graphql Schema: For a GraphQL API, the name of the schema definition that references the imported GraphQL schema. For information on uploading a schema during GraphQL API creation, see Creating a GraphQL proxy API. For information on replacing the schema for an existing GraphQL API, see Using the GraphQL schema editor.
   - Exxtensions: Extensions added to the API to extend the OpenAPI specification. For details, see Adding an OpenAPI extension to an API.

Defining target services for an API

A target service defines a web service that you want to use in your API definition.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more target services defined, expand Target Services.
3. To define a new API target service, complete the following steps:
   a. Click the add icon alongside Target Services in the navigation pane.
   b. Upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, by either dragging and dropping your file, or browsing and selecting the file that you want to use.
   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.

   The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.
4. Select the service that you want to add.
5. Click Save to save your changes.
6. To view the source for an existing target service, click the target service name in the navigation pane.

Results

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.

Setting API properties

In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API properties include property name, value, and, optionally a specific Catalog to which a property value applies. For a list of pre-supplied API properties relating to various policies, see API properties.
Note: Once defined, an API property is read only.
For information on how to reference a property in an API definition, see Variable references in API Connect.

It is also possible to define properties that are specific to a Catalog and can be referenced by any of the APIs in that Catalog; for more information, see Creating and configuring Catalogs. Note that if you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more API properties defined, expand Properties.
3. Configure an API property.
   - To define a new API property, complete the following steps:
     - Click the add icon ⊕ alongside Properties in the navigation pane.
     - Provide the following information:
       - Property Name: Enter a name for the property; this name is used to reference the property. The following character set is supported for the name of an API property: `[A-Za-z0-9_-]+`. Spaces are allowed.
       - Property Value: A default value for the property. Leave blank if the property is to have a null vale by default.
       - Description: An optional description of the property. You can use CommonMark syntax for rich text representation.
       - Select Property Value is Base64 Encoded if you want to hide the property values, or protect user passwords from casual observance.
         Note: If you encode a property value, it is saved in Base64 encoded form; it is **not** encrypted. If you subsequently clear the Encoded check box, the original property value is restored in its unencoded form.
     - Click Create.
   - To modify an existing API property, click the property name in the navigation pane. You can then change any of the configuration settings.
4. Click Save to save your changes.

- **Defining Catalog specific property values**
  For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Defining Catalog specific property values

For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Before you begin

You must have previously created the API property that you now want to define a Catalog specific value for; see Setting API properties.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more Catalog specific property values defined, expand Catalog Properties.
3. Configure a Catalog specific property value.
   - To define a new Catalog specific property value, complete the following steps:
     - Click the add icon ⊕ alongside Catalog Properties in the navigation pane.
     - Type the Catalog Name exactly as it displays in the `name` field for the selected Catalog.

Tip: For the best result, manually type the catalog's name instead of selecting its title. Using the catalog name is safer than using its title, because the title might not be unique within the provider organization and might be modified later (which breaks the association between the property and the catalog). The catalog's name is always unique within the provider organization and cannot be changed.

- Click Create. The Catalog properties details for the specified catalog are displayed for further editing.
- Alongside Property Overrides, click Add.
- Provide the following information:
  - Property Name to Override: Enter the name of the API property that you want to define a Catalog specific value for. The name **must** match the name of a previously defined API property; see Setting API properties.
  - Property Value: The Catalog specific property value. Leave blank if the property is to have a null value by default.
- Click Create.

- To modify an existing Catalog specific property value, click the Catalog name in the navigation pane. You can then change the Catalog name, and add, modify, or delete property override settings.

4. Click Save to save your changes.

Configuring application authentication for an API

Using this topic, you can configure application authentication for an API.

About this task

Remember: Sending the client certificate in an HTTP header does not enable cryptographic verification that the caller possesses corresponding to the private key. The only validation performed is a string comparison of the base64-encoded PEM file with the public certificate that you can configure following the steps below.
Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Enable application authentication, as follows:
   Note: To identify the application, you must enable a security requirement of type `clientID`.
   a. On the API Design page, select the Gateway tab and expand Gateway and portal settings.
   b. In the navigation pane, click Application Authentication.
3. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header. Specify how the client certificate is sent to the gateway, as follows:
   You can choose to send the client certificate as a TLS client certificate, or to include it in the API's HTTP header.

   a. In the navigation pane, click Application Authentication.
      Any existing application authentication source definitions are listed.
   b. On the Application Authentication page, select Certificate.
   c. In the Application pane, click Application authentication source.
   d. On the Application authentication source page, click Add.
   e. In the Add shema dialog box, select the required option .
      - tls-cert - When the API is called, the TLS client certificate is sent to the Gateway service and is used to verify that the API caller holds the corresponding private key.
      - header - When the API is called, an X509 client certificate must be supplied in the specified HTTP header. For any Developer Portal application that calls the API, the certificate must be entered in the Developer Portal user interface; for details, see Registering an application. If you are using a load balancer, you must configure the load balancer to use the specified HTTP header to relay the appropriate client certificate to the Gateway service after the load balancer terminates the TLS communication.

      Attention: Sending the client certificate in an HTTP header does not allow for cryptographic verification that the caller holds the corresponding private key. The only validation performed is a string comparison of the base64-encoded PEM file against the client certificate.
   f. If you select the tls-cert option, enable mTLS at the Gateway level.
      Enable mTLS by setting "Mutual authentication: Required" (or "Requested" if not all APIs use mTLS) in the TLS Server Profile that is specified for the API invocation endpoint in your gateway service configuration. The gateway service is configured in the Cloud Manager UI (requires cloud administrator permissions). For more information, see Registering a gateway service and TLS profiles overview.

      You can create a truststore (with the root or intermediate CA certificate) for use with the TLS Server Profile.

      The following example cURL command uses a client-cert during SSL:

      ```
      **curl -X GET 'https://GW-Server:9443/test/sandbox/mtls-testing/callmtls-call' -H 'X-IBM-Client-Id:
      1872xxxxxxxxxxxx' --cert my-leaf-cert.pem --key my-leaf-cert.key -k -v**
      ```

      Note: This feature is intended for the scenario where different applications are registered with different end certificates in the Developer Portal, which have the same intermediate or root CA issuer. The certificate passes Gateway-level mTLS if it matches the issuer available in the truststore, but allows access only to the API that matches the correct end certificate.
4. Click Add.
5. Click Save to save your changes.

Configuring activity logging

You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An API event record exists for each API execution event in the Gateway server. By default, the content type for a successful API execution is activity, and payload for an API call the results in an error code. When you compose your API definition, you can change the type of content to log in these API event records. During API execution, the activity data is stored in the `log` context variable, which populates the API event record on completion of the API execution; for more information, see API activity logging context variables.

Note:
Activity logging that calls for logging of analytics data upon success doesn't apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but doesn't log successful cases.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Activity Log.
3. Select Enabled, then select options for the Success Content and Error Content fields as follows:

Field label	Description
Success Content	Defines the type of content to be logged when the operation is successful. • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is activity.
Error Content	Indicates what content to log when an error occurs. • none: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • activity: Logs invocation only; only the resource URI is recorded. • header: Logs activity and header; the HTTP headers, in addition to the resource URI are recorded. • payload: Logs activity, header, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is payload.
Preserved request header	Click Add to specify customized request headers to preserve for logging to analytics. The preserved request header property ensures that specific request headers added through a log action with gather-only, followed by a GatewayScript or Set Variable policy, are retained in analytics logging. Normally, such added headers are discarded when the API Gateway processes analytics records, replacing modified headers with the original ones. This property specifies which added request headers should be maintained in analytics logs when the original request headers overwrite updates.
Preserved response header	Click Add to specify customized response headers to preserve for logging to analytics. The preserved response header property ensures that response headers, that are added using a log action with gather-only and further modified by a GatewayScript or Set Variable policy, are preserved in analytics logs. Without the Preserved Response Header property, the API Gateway discards the added headers in some cases by reverting to the original response headers in the log record.

4. Click Save to save your changes.

Configuring v5 compatibility options

You can configure settings to ensure compatibility with API Connect Version 5.0 compatible APIs that are converted for use with the DataPower API Gateway.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Compatibility.
3. Select from the following options as required:
   - Return V5 Responses: Return v5-compatible responses, such as OAuth and client security error responses.
   - Copy Id Headers to Message: Copy security headers to the message context for retrieval by the invoke back-end service.
   - Enforce Required Params: Check the request for required parameters during API routing. When enabled, a request that does not provide a required parameter is rejected.

- Allow Chunked Uploads: Allow the assembly `invoke` policy to send documents to the server with `Transfer-Encoding: chunked`. This setting applies only to the `invoke` 1.5.0 wrapper policy deployed from API Connect using the migration utility. It does not apply to the native API Gateway assembly `invoke` policy.

4. Use the YAML source to set the following options as required:

Option	Valid values	Description
`allow-trailing-slash`	`true / false`	Specify whether to allow the request URL to end with a / character. The default value is `false`.
`get-raw-body-value`	`true / false`	Specify whether the GatewayScript `apim.getvariable()` API returns the raw body instead of parsing. This setting applies only when the context is other than `message`. The default value is `false`.
`request-headers`	`true / false`	Specify whether to populate v5-compatible headers such as `X-Client-IP` and `X-Global-Transaction-ID` in the `request.headers` context variable. The default value is `false`.

5. Click Save to save your changes.

Including elements in your API assembly

An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
In the Policies view of IBM® API Connect, you can add and configure elements in your assembly. You can also directly add elements to the OpenAPI definition of your API.

- **The assembly editor**
  The API Designer of IBM API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.
- **Adding elements to your assembly**
  Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.
- **Handling errors in the assembly**
  Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

The assembly editor

The API Designer of IBM® API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can access the Assemble view by clicking the Gateway tab in the API editor, and then click Policies. This tab includes the following options:

- Palette - lists the available elements in the assembly flow.
- Canvas - used to arrange and visualize the elements in the assembly.
- Property sheet - used to configure the elements in the assembly.

The palette

The palette is a list of different elements that you can include in your assembly. To view the palette, click the plus icon ⊕ on the canvas. You can use the Rotate icon ↻ to rotate the palette as you prefer. To maximize and minimize the palette view, click the Maximize and Minimize icons.

You can release the palette by clicking the Close icon ✕.

The canvas

You can use the canvas to create a graphical representation of the assembly flow. To add an element to the assembly flow from the palette, click the plus icon ⊕ at the appropriate location on the canvas and select the required element from the available list. To delete an element from the canvas, hover over the element and click the Delete icon 🗑.

Note: You must click Save in the Assemble view to save your assembly updates, and to make them appear in the Source view.
API calls are made at the initial, unfilled, circle, and returned at the final, filled, circle. You can insert elements between the two circles to modify the data received from the call, or returned by the response.

You can use the Show catches toggle to show and hide error catches in the palette. A catch is a section of the assembly that is applied when an API call results in the corresponding HTTP status code being returned. Click the catch section to open the property sheet for all your catches.

You can zoom the view of your canvas in and out by clicking the + and - icons. To fit the canvas to the screen size, click the Fit to screen icon ⛶.

The property sheet

When you select an element in the assembly by clicking it, details about the element are displayed in the property sheet. In this pane, you can configure the element's properties. The options available to you in the property sheet are specific to the type of element that you are working with. For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down menu.

You can release the property sheet by clicking the Close icon ✕.

The behavior of an assembly

The assembly runs policies in order and acts on different contexts of the API call. When an API call is made, security and rate limits are enforced before the assembly is executed. During the assembly, the flow can be branched, thrown, and caught according to the policies available. The message context flows through the assembly, being used and altered by various policies. In addition to the message, other contexts can be accessed and created.

Security and rate limiting

Before the assembly is executed, security and then rate limits are enforced.
First, security definitions and CORS access control are used to authenticate an API call. Any API Key security definitions are used to identify applications that have subscriptions to a Product containing the API. If a security definition does not allow access, the API call is rejected.

If an application is identified by its client ID or client secret, a rate limit can be enforced based on the Plan or operation called.

The assembly execution sequence

The assembly is executed in order from the initial, filled, circle to the final, unfilled, circle. However, there is room for branching, when **`if`** and **`operation-switch`** logic constructs are used, or for the remaining assembly to be ignored when a **`throw`** policy is executed.
The message is the context that is acted upon by any policy that isn't otherwise configured. At the beginning of the API call, the message is empty and at the end of the API call, the message is used as the response.

The request context contains the information that is sent by the API caller and varies with the type of operation called as well as the configuration of that operation. For example, a GET operation can never have a populated **`request.body`**, and you can configure an operation to have **`request.parameters`** (query parameters). The first policy in an assembly acts on the request and produces the first instance of the message. If there are no policies, the request is returned to the caller.

Managing contexts

Because the message can be overwritten, it is useful to create and reference new contexts where possible so that they are saved and reused during the API call.

- Use the **`map`** policy to overwrite the message context when you need to execute a policy that only acts on the message.
- Use the request context when you want to use the original request made to the API.
- Use the **`map`**, **`invoke`**, and **`proxy`** policies to create new contexts when you want to save your message.
  Note: When you create a new context, unless you are also mapping to the message, the message is overwritten with an empty object.

For example, **`invoke`** is the first policy in the assembly and its response overwrites the request as the message. The message is then acted upon by a **`validate`** policy, and a **`map`** policy then saves the message as a new context, ready for a second **`invoke`** policy to overwrite the message without losing the first **`invoke`** policy's output.

You can also access contexts outside of the message or your custom contexts, but these contexts cannot be written to. For a list of contexts, see API Connect context variables.

Branches and catches

Using logic constructs, such as **`operation-switch`** or **`if`**, you can execute different sections of the assembly when certain conditions are fulfilled. When the assembly branches, the subsection of the assembly contained by the construct is executed in the same manner as a complete assembly. However, contexts are shared with the complete assembly.
When a catch is triggered, either by an error occurring during the execution of a policy or because a **`throw`** policy is encountered, the rest of the assembly flow is ignored. All contexts are shared by the catch being executed and when the end of the catch is reached, the API call is completed. There is no way to return from a catch to the rest of the assembly.

- API Connect context variables

Adding elements to your assembly

Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can use the assembly tool in the UI to create assemblies that are used to manipulate requests made to or responses made by any of your API's operations.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

If you want to use the Source view to edit the source of your API definition, see execute OpenAPI extension for more information about how to configure the OpenAPI YAML.

For more information about the use of the assembly tool, see The assembly editor.

Procedure

To add elements to your assembly using the assembly tool, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Use the Policies view to add an element.
   Note: You must specify a version for the policy. To prevent errors due to incompatible versions of a policy between the API and the gateway, API Connect will only publish an API to the gateway if the policy version in the API exactly matches the version present on the gateway.
   a. Select the Gateway tab, then click Policies in the navigation pane.
   b. Click the plus icon at the appropriate location on the canvas to view the palette that lists the available elements.
   c. Select the element that you want to add from the palette to the canvas by clicking it.
      Note:
      - Elements are applied in order from the initial, unfilled, circle to the final, filled, circle.
      - Unless an Operation Switch element is used, the whole assembly applies to every operation in the API.
   d. Add and edit the element properties by clicking the element and using the property sheet.
      For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down list. For information about the properties of policy elements, see API policies and logic constructs. For information about the properties of logic constructs, see Logic Constructs.
   e. Specify a version for the policy.
      To add a version, click the Source icon </>, and complete the **version** section of the policy YAML. For example:

      ```
      execute:
        - invoke:
            version: 2.2.0
            title: invoke
      ...
      ```

      You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions. For more information about how to configure the policy OpenAPI YAML, see execute OpenAPI extension.
4. Optional: Repeat Steps 3.b to 3.e for any additional elements that you want to add.
5. Click Save to save your changes.

Results

You have added one or more elements to your assembly.

Handling errors in the assembly

Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

About this task

Note: This task relates to configuring an OpenAPI 2.0 API definition. For details on how to configure an OpenAPI 3.0 API definition, see Editing an OpenAPI 3.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The catch section of the assembly is used to implement an assembly in the instance that an error is thrown during the assembly execution. For example, the assembly could contain a **throw** element, the API caller could fail to authenticate, or a policy could fail to execute correctly. Each error can be handled with a different catch and each catch can handle multiple status errors.

Procedure

To create a catch and include elements in it, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to apply a catch to.
3. Select the Gateway tab, then click Policies in the navigation pane.
4. Set the Show catches toggle in the menu bar of the canvas to the Show position.
5. Click Catches in the canvas, or a Catch icon if one is displayed.
   The property sheet for the API's catches opens.
6. To add a default catch that is executed when an otherwise uncaught error is thrown, click Add default catch.
   Note: If you have a default catch before another catch in precedence, the default catch will activate even when the other catch's error is thrown.
7. To add a new catch, click Add catch.
8. To specify which errors the catch applies to, use the Select errors field and select the appropriate error.
9. Optional: To remove an error case from a catch, clear the corresponding checkbox from the Select errors drop-down. To clear all the error cases from a catch, click the cross corresponding to the total number of error cases in the Select errors field.
10. Optional: To change the precedence of your catches, use the Move up ↑ or Move down ↓ icons.
    If an error case is handled by multiple catches, the catch at the beginning of the list is applied.
11. To add an element to a catch from the palette, click the plus icon at the appropriate location in the assembly flow. Select an element that you want to apply to the catch by clicking it.

12. Click Save to save your changes.

What to do next

If you added a catch for ConnectionError, SOAPError, or OperationError, you must add the same error to the Stop on error setting for the **Invoke** policy in your assembly. Otherwise, if the error occurs during the execution of the **Invoke** policy, it is not caught, the policy execution is allowed to complete, and the assembly flow continues. For details on configuring an **Invoke** policy, see Invoke.

For details of all the errors that can be returned by the assembly and are available to the catch function, see Error cases supported by assembly catches.

Specifying the gateway type for an API definition

An API definition is specific to one or other of the gateway types, DataPower® API Gateway or DataPower Gateway (v5 compatible). A default gateway type is set when you create an API definition, but you can edit the API configuration to specify a different gateway type.

About this task

Note: This task relates only to an OpenAPI 2.0 API definition. An OpenAPI 3.0 API is supported only on the DataPower API Gateway.
DataPower Gateway (v5 compatible) has been available with IBM® API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

For more information on how to choose which gateway type to use, see API Connect gateway types.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You must specify which type of gateway each API uses. APIs can use only one type of gateway.

When you create a new API definition, or import an API definition that has no gateway type configured, the gateway type defaults according to the gateway types of the gateway services that are enabled in your Sandbox Catalog, as indicated in the following table.

Table 1. Default gateway type for a new API definition

Gateway Service enablement in Sandbox Catalog	Default gateway type for new API definition
No gateway services enabled	DataPower API Gateway
At least one gateway service of each type enabled	DataPower API Gateway
One or more gateway services only of type DataPower API Gateway enabled	DataPower API Gateway
One or more gateway services only of type DataPower Gateway (v5 compatible) enabled	DataPower Gateway (v5 compatible)

If you import an API definition that already has a gateway type configured, that gateway type is retained.
Note that when you modify your API definitions to use a specific gateway type, you must ensure that each policy and policy version in the API are supported by the gateway type. DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

For example, DataPower Gateway (v5 compatible) supports version **1.0.0** of the **invoke** policy, but DataPower API Gateway requires version **2.0.0**.

For information on policies, see execute.

For information on policy versions, see the documentation for each individual policy. For example, to review the **invoke** policy, see invoke.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Click the title of the API you want to update.
3. Select the Gateway tab, then click Gateway and portal settings.
4. Select the type:
   - datapower-gateway for the DataPower Gateway (v5 compatible)
   - datapower-api-gateway for the DataPower API Gateway.

   Note: The Gateway Type selection is not applicable if the Enforced option is disabled, because an unenforced API is not managed on an API Connect gateway.
5. Click Save to retain the changes.
6. In the navigation pane, select Policies to ensure that your API uses policies that are supported by the gateway type you selected.

   Policies in an existing API that are not supported by the new gateway type are grayed out and flagged with a red exclamation point: .

   Some policies are supported by only one gateway type. Some policies are supported by both gateway types, but require a different version of the policy for each gateway type.

Related tasks

- Converting an API definition for deployment to the DataPower API Gateway

Converting an API definition for deployment to the DataPower API Gateway

IBM® API Connect provides two gateway types, DataPower® Gateway (v5 compatible) and DataPower API Gateway. If you have an API definition that was developed for the DataPower Gateway (v5 compatible) and you want to port it to the DataPower API Gateway, you must make changes to convert it before deployment.

About this task

Note: This task relates only to an OpenAPI 2.0 API definition. An OpenAPI 3.0 API is supported only on the DataPower API Gateway.
DataPower Gateway (v5 compatible) has been available with IBM API Connect for a number of years. The DataPower API Gateway is a new gateway that has been designed with APIs in mind, and with the same security focus as DataPower Gateway (v5 compatible).

To convert an API for deployment to the DataPower API Gateway, you must, as a minimum, change the gateway type setting on the API definition, and ensure that each policy and policy version in the API are supported by the DataPower API Gateway; DataPower Gateway (v5 compatible) and DataPower API Gateway each support policies that the other gateway type does not. In some cases, the same policy is supported by both gateway types, but with a different version number.

In addition, depending on the specific policies in your API assembly, some policies might require modification to adapt them for use with the DataPower API Gateway.

The following procedure provides instructions for converting your API definition:

Procedure

1. Set the gateway type for the API to DataPower API Gateway, and ensure policy type and version compatibility. For details, see Specifying the gateway type for an API definition.
2. Refer to the DataPower API Gateway porting notes for detailed instructions on how to convert your API definition.

Modifying a GraphQL schema

For a GraphQL API, an editor is provided for modifying the associated GraphQL schema.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To open the GraphQL schema editor for a GraphQL API, complete the following steps:

1. Open the API for editing, as described in Editing an OpenAPI 2.0 API definition.
2. Select the GraphQL Schema tab.

What to do next

For full details on how to use the editor, see Using the GraphQL schema editor.

Validating the OpenAPI YAML source

How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.

About this task

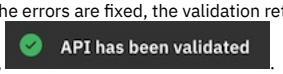
When you're configuring an API in the API editor, you can validate the OpenAPI YAML source by clicking Validate > With specifications. If any swagger parser validation errors are found, an error icon is displayed that you can then click to see the individual errors, and where they occur in the YAML. You can then fix the errors, save the updates, and continue to validate the OpenAPI YAML throughout the API configuration process.
Note:

- OpenAPI validation does not show gateway or policy errors that will stop your API from being staged or published. This type of validation occurs only when you try to stage or publish your API. For more information, see Staging an API or Publishing an API.
- You can also validate your API document by using governance rulesets. For more information, see Validating an API or product document by using the governance service.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To validate the OpenAPI YAML source, complete the following steps.



1. Open the required API for editing, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
2. Click Validate > With specifications from the menu bar in the header.

3. If any swagger parser validation errors are found, an error icon is displayed on the header menu bar, with the number of OpenAPI errors found displayed next to the icon.

For example,  .

4. You can then click the error icon to see a detailed list of the errors, and their location in the YAML. If you're in Form view, you can click an individual error to navigate directly to the relevant API section in the form.
5. After you fix the error, click Save to save your updates, and then click Validate again.
6. When all of the errors are fixed, the validation returns a success message.

   For example, 

.

Validating an API or product document by using the governance service

How to use governance rulesets to validate and enforce organizational governance policies and best practices. You can run validation scans on API and product documents from the API Manager UI, the API Designer UI, or the toolkit CLI.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. See Enabling governance on Kubernetes, and Enabling governance on VMware for more information. If governance is enabled in your deployment, the Governance icon  is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

The governance service is available to all user roles.

Tip: Before using the governance service to validate any API documents, you should first run Validate > With specifications to validate the OpenAPI YAML source. For more information, see Validating the OpenAPI YAML source.

About this task

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API and product development process. The service contains the following types of rulesets:

API
: Rulesets to validate your API documents.

  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating APIs.
  - Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization for validating APIs, and cannot be edited. Note that the Spectral ruleset names are prefixed by spectral-, and that their version matches the version of that ruleset that's available in Spectral.

Product
: Rulesets to validate your product documents. Note that the validation scan of products looks only at the product yaml; it does not include the scanning of any API documents that the product refers to.

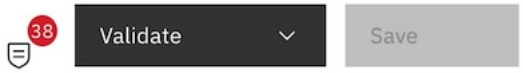
  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating products.
  - Global rulesets - these are pre-configured custom rulesets that contain the rules that are shared with your provider organization for validating products, and cannot be edited.

You can create your own provider organization rulesets to validate your Swagger, OpenAPI, AsyncAPI, and product documents against, or use the global rulesets that are provided for your organization. For more information about configuring rulesets, see Configuring governance in the API Manager.

Governance in API Connect is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

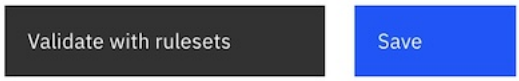
You can complete the instructions that are in this task by using the API Manager UI, or by using API Designer when the UI is online, and is connected to a cloud instance that has the governance microservice enabled on it. You can also use the toolkit CLI; for details see Validating an API or product document by using the toolkit CLI.

The following validation scan methods are available:



- Validate an API document from within an API
- Validate a product document from within a product
- Validate one or more API or product documents from within the Governance section
- Validate one or more published API or product documents from within a catalog or space

Procedure



- To validate an API document from within the API, complete the following steps.
  1. Open the required API for validating, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
  2. Click Validate > With rulesets from the menu bar in the header.

  3. Select the rulesets that you want to validate your API document against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. The API can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
     The API Design page is displayed.
     If validation errors were found during the scan, the ruleset status icon in the header menu bar displays the number of errors found, for example:

     You can click on the ruleset status icon to see a detailed list of the errors, and their location in the YAML. You can also then click on an individual error to navigate directly to the relevant section in the API.
- To validate a product document from within the product, complete the following steps.
  1. Open the required product for validating, by clicking on the title of the product in the Products tab of the Develop page.
  2. Click Validate with rulesets from the menu bar in the header.

  3. Select the rulesets that you want to validate your product document against, and click Next.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. The product can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
     The product Design page is displayed.
- To validate one or more draft API or product documents from within the Governance section, complete the following steps.
  1. In the side menu bar, click  Governance.
     The Governance page is displayed.
  2. Click the Rulesets tab.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.
  7. Select the APIs or products that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
  8. Optional: You can click Download to download the results of the validation into a .csv file.
  9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  10. Click Done when finished.
- To validate one or more published API or product documents from within a catalog or space, complete the following steps.
  1. Select the catalog or space that you want to run the validation in, and then select Governance from the menu bar.
  2. Select Rulesets.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.
  7. Select the APIs or products that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
  8. Optional: You can click Download to download the results of the validation into a .csv file.
  9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  10. Click Done when finished.

Results

Your API or product document is validated against one or more rulesets.

What to do next

You can use the results of the validation to help you improve your API or product document. You can also use the results to help you edit the rulesets, and create new rulesets; see Configuring governance in the API Manager for more information.
You can also run validation scans on a catalog or space, to check one or more of the API documents that it contains. For more information, see Scanning your catalogs and spaces.

Related information

- The governance ruleset lifecycle

Validating an API or product document by using the toolkit CLI

How to use the API Connect toolkit CLI to run governance validation scans on your API or product documents.

About

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API development process. The following information provides details of the toolkit CLI commands for running and managing validation scans on your API or product documents. You can also validate an API or product document by using the API Manager and the API Designer UIs. For more information about validation scanning, see Validating an API or product document by using the governance service.

The following validation scan methods are available by using the toolkit CLI:

- Validate a single API or product document that is stored locally
- Validate one or more API or product documents that are stored on the management server

Validate a single API or product document that is stored locally

To run a validation scan on a single API or product document against one or more rulesets, complete the following steps. The document must be stored locally.

1. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

   ```
   apic login --server platform_api_host_name --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Run the **compliance:validate** toolkit command in `governance` mode.

   ```
   apic --mode governance compliance:validate --org <target_org> --server <platform_api_host_name> --rulesets
   <ruleset_name_1>,<ruleset_name_2> API_OR_PRODUCT_FILE
   ```

   where:
   - `<target_org>` is the name of the provider organization that owns the APIs to be validated.
   - `<platform_api_host_name>` is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - `<ruleset_name_1>,<ruleset_name_2>` is a comma-delimited list specifying the names of the rulesets to be applied to the API or product. (Specify each ruleset name; do not use the ruleset IDs.)
   - `API_OR_PRODUCT_FILE` is the path and filename of the document to be validated.

Validate one or more APIs or products that are stored on the management server

This operation runs a validation scan on all of the draft APIs, or all of the products, that are listed in the `COMPLIANCE_REQUEST_FILE`. You can scan only APIs, or only products, at any one time. The APIs must be stored as draft APIs in your provider organization.

1. Create a JSON `COMPLIANCE_REQUEST_FILE` that specifies the rulesets to use during validation, and the location of either the draft APIs or the products that you want to scan. The file can contain URLs only for APIs, or only for products; you cannot list both API and product URLs in the same file.
   The following example shows a configuration file that specifies two draft APIs, and two rulesets. In the `spectral-oas` ruleset, the `info-contact` rule is disabled and will be ignored during validation.

```
{
  "apiUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/a08898fe-b422-41d3-b058-c3280d632e93","https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/26692eab-f43b-4af3-985c-2deaa401eb7f"],
  "config" : {
    "rulesets": [
      {
        "rulesetName": "spectral-oas",
        "disabled": ["info-contact"]
      },
      {
        "rulesetName": "spectral-owasp",
        "disabled": []
      }
      ]
 }
}
```

The following example shows a configuration file that specifies one product document.

```
{
  "productUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-product/a07968fe-b422-41d3-b058-c3280d632e93"],
  "config" : {
    "rulesets": [
      {
        "rulesetName": "product-info",
        "disabled": ["subscribe"]
      },
      {
        "rulesetName": "product-rate",
        "disabled": []
      }
      ]
 }
}
```

Where:

- **`apiUrls`** is a comma-delimited list of API URLs. Each URL specifies the location of the draft APIs in a particular provider organization.
- **`productUrls`** is a comma-delimited list of product URLs. Each URL specifies the location of the product document in a particular provider organization.
- **`rulesetName`** is a list of rulesets to be applied to the APIs or products during validation.
  For each ruleset in the list, you can optionally add the **`disabled`** property with a comma-delimited list of rules to ignore during validation.

2. Log in to the toolkit as the owner or an admin of your provider organization. See Step 1 for details.
3. Run the **compliance:validate_all** toolkit command in **`governance`** mode.

```
apic --mode governance compliance:validate_all --org <target_org> --server <platform_api_host_name>
COMPLIANCE_REQUEST_FILE
```

where:

- ***`<target_org>`*** is the name of the provider organization that owns catalog containing the APIs to be validated.
- ***`<platform_api_host_name>`*** is the hostname portion URL of server that hosts the API Manager (the "management server").
  Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **`https://`** and ending before **`/manager`**).
- ***`COMPLIANCE_REQUEST_FILE`*** is the path and filename of the configuration file that lists the API or product documents, and the rulesets to be used during the validation (for example, validate-apis.json).

Editing an OpenAPI 3.0 API definition

IBM® API Connect provides a form based editor that enables you to configure APIs that conform to the OpenAPI 3.0 specification.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

You can open an API for editing in either of the following ways:

- During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
- To open an existing API for editing, complete the following steps:
  1. In the navigation pane, click  Develop, then select the APIs tab.
  2. Click the title of the API version that you want to work with.

- **OpenAPI 3.0 support in IBM API Connect**
  IBM API Connect supports the OpenAPI 3.0 specification, with some limitations. The current implementation includes complete support for the Berlin Group NextGen PSD2 requirements.

- **Specifying API metadata**
  API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.
- **Defining servers for an API**
  Server definitions in an API provide information for connecting to target servers.
- **Enforcing security requirements on an API**
  To enforce security requirements on an API, you apply previously created security scheme components that define various aspects of API security configuration.
- **Specifying external documentation for an API**
  You can reference an external resource for extended documentation for an API.
- **Adding tags to an API**
  You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Defining Paths for an API**
  A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.
- **Defining components for an API**
  Components are reusable objects relating to various aspects of your API definition. A component has no effect on the API unless it is explicitly referenced from elsewhere in your API definition.
- **Specifying gateway and portal settings**
  Define general configuration settings for your API.
- **Defining target services for an API**
  A target service defines a web service that you want to use in your API definition.
- **Setting API properties**
  In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.
- **Configuring application authentication for an API**
  Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.
- **Configuring activity logging**
  You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.
- **Including elements in your API assembly**
  An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.
- **Validating the OpenAPI YAML source**
  How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.
- **Validating an API or product document by using the governance service**
  How to use governance rulesets to validate and enforce organizational governance policies and best practices. You can run validation scans on API and product documents from the API Manager UI, the API Designer UI, or the toolkit CLI.

OpenAPI 3.0 support in IBM API Connect

IBM® API Connect supports the OpenAPI 3.0 specification, with some limitations. The current implementation includes complete support for the Berlin Group NextGen PSD2 requirements.

Overview

A Product can contain any combination of OpenAPI 2.0 and OpenAPI 3.0 APIs. When you publish a Product that contains an OpenAPI 3.0 API, that API is validated to ensure that it is syntactically correct, and that references to configuration resources and policies resolve correctly, in the same way that OpenAPI 2.0 APIs are validated.

You can also validate OpenAPI 3.0 APIs in your local file system by using the **`apic validate`** command provided by the developer toolkit CLI; for details, see Validating the YAML or JSON definition of an API or Product.

If you retrieve an API object by using the developer toolkit CLI or the API Connect REST APIs, there is an **`oai_version`** property that defines which OpenAPI version the API represents.

There is no OpenAPI 3.0 API support with the DataPower® Gateway (v5 compatible); OpenAPI 3.0 API support is provided by the DataPower API Gateway **only**.

Limitations

The limitations to the OpenAPI 3.0 support in API Connect are as follows:

User interface limitations

- Some aspects of the OpenAPI 3.0 specification are not currently supported by the user interface. In such circumstances, use the OpenAPI source directly.
- Validation errors that are identified locally are reflected in the API editor header almost immediately. However, some validation errors can be identified only by the API Manager backend and are not reflected until the API is saved; this means that, on saving an API, some validation errors might appear or disappear.
- The user interface does not currently support referencing a request body component from the request body of an operation. If you want to reference a request body component, add the reference to the request body of the operation directly in the OpenAPI source:

  ```
  requestBody:
    $ref: '#/components/requestBodies/request_body_component_name'
  ```

  The reference **is** confirmed on the details page for the request body in the user interface however.
- If, in the API Designer user interface, you create and activate an API of the same name and version as one that has already been activated from the API Manager user interface, the Edit Rate Limit operation fails.

Limitations for APIs that are enforced by the DataPower API Gateway

To suppress the error message for the following limitations and publish the API, set the **`x-ibm-configuration.compatibility.suppress-limitation-errors`** property to **`true`** as shown in the following example:

```
compatibility:
  suppress-limitation-errors: true
```

Attention: Enabling **suppress-limitation-errors** merely disables the error messages so that the API can be published.

- General limitations.
  - The **servers** array cannot contain more than one server.
  - The **url** entry in the **servers** array cannot contain **variables**.
  - The **path** objects cannot contain server object overrides.
  - There is no support for converting a WSDL defined SOAP service into an OpenAPI 3.0 API.
  - There is no support for callbacks or links, and APIs containing them will not be published.
  - The following constructs of Open API 3.0 are less commonly used, and are not supported:
    - **allowEmptyValue**
    - **allowReserved**
  - A **parameter** object cannot contain an **explode** keyword with a value of `true`.
  - A **path** or **header** parameter object must have or default the **style** keyword to `simple`.
  - A **query** parameter object must have or default the **style** keyword to `form`.
- Assembly policies.
  - All policies are supported.
  - JSON schema support is limited to Draft 4 and earlier. Therefore, the following policies are limited to those drafts:
    - **gatewayscript**
    - **set-variable**
    - **switch**
    - **json-to-xml**
    - **xml-to-json**
    - **parse**
    - **xslt**
    - **map**
    - **validate**

    For detailed information about the Draft 4 and earlier specifications, see https://json-schema.org/specification-links.html#draft-4.
  - Security.
    - The OpenID Connect (OIDC) security scheme is not supported.
    - The use of cookies in an API key is not supported.

Specifying API metadata

API metadata provides summary information about the API. You enter API metadata in the Info section of the API definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand the General section, then click Info.
3. Provide the following information:
   - Title (required): The title of the API.
   - Name: The name was generated automatically when the API was created and cannot be changed. The value in the Name field is a single string that is used to identify the API in developer toolkit CLI commands. To view the CLI commands to manage draft APIs, see the toolkit CLI reference documentation.
   - Version: The API version is specified when the API is initially created and cannot be changed thereafter. You can, however, create a new version of an existing API; see Creating a new version of an API definition.
   - Description: An optional description of the API. You can use CommonMark syntax for rich text representation.
   - Terms of Service: A URL to the Terms of Service for the API.
   - Contact Name: The identifying name of the contact person/organization.
   - Contact URL: A URL pointing to the contact information.
   - Contact Email: The email address of the contact person/organization.
   - License Name: The license name used for the API.
   - License URL: A URL to the license used for the API.
4. Click Save when done.

Defining servers for an API

Server definitions in an API provide information for connecting to target servers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand General then, if there are already one or more servers defined, expand Servers.
3. To create a new server definition, click the add icon ⊕ alongside Servers in the navigation pane. To edit an existing server definition, click the server URL in the navigation pane.
4. Provide the following information:
   - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

     ```
     /my_basepath
     ```

     For full details on how the server URL is used to determine the full URL endpoint, see Configuring vanity endpoints for a Catalog.
   - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
   - Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
     - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
     - Provide the following information:
       - Server Variable Name (required).
       - Default value (required).
       - An optional rich text description. You can use CommonMark syntax for rich text representation.
       - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
     - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
     - If required, use the breadcrumb trail to return to your server definition for further editing.
5. If you are creating a new server definition, click Create.
   The server definition details are displayed for further editing as described in step 4.
6. Click Save when done.

Enforcing security requirements on an API

To enforce security requirements on an API, you apply previously created security scheme components that define various aspects of API security configuration.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme components, see Defining security scheme components.

The following restrictions exist when you apply security schemes to an API:

- You cannot apply more than two API key security schemes to an API.
- If you apply an API key security scheme for client secret, you must also apply an API key security scheme for client ID.
- If you require the application developer to supply both client ID and client secret, you must apply two separate API key security schemes.
- You can have at most one API key scheme of type client ID, regardless of whether the client ID is sent in the request header or as a query parameter.
- You can have at most one API key scheme of type client secret, regardless of whether the client secret is sent in the request header or as a query parameter.
- You cannot apply more than one basic security scheme to an API. If you apply a basic security scheme, you cannot also apply an OAuth security scheme.
- You can apply at most one OAuth security scheme to an API.

A security requirement specifies one or more security scheme components whose conditions must all be satisfied for the API to be called successfully. You can define multiple security requirements; in this case, an application can call your API if it satisfies any of the security requirements you have defined.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand General.
3. To create a new security requirement for the API, complete the following steps:
   a. Click the add icon alongside Security in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined in security scheme components; see Defining security scheme components.
   If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme component; for more information, see Defining OAuth2 security scheme components.

   If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

   Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Submit when done.
4. To modify an existing security requirement, complete the following steps:
   a. Click Security in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
   c. Click Submit when done, then click Save.
   d. To delete a security requirement, click the appropriate delete icon, click Delete to confirm, then click Save.
   e. To disable security for the API, clear the Require one of the following Security Requirements check box, then click Save.

What to do next

Fore more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

- **Enabling CORS support for an API**
  You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Enabling CORS support for an API

You can enable cross-origin resource sharing (CORS) support for your API. CORS allows embedded scripts in a web page to call the API across domain boundaries.

Before you begin

This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.

About this task

Note:

- CORS support is available only on the DataPower® API Gateway.
- When CORS is enabled, the API Gateway runs the `cors` preflow policy to handle all CORS requests that are made to the API.
- When CORS is enabled and a preflight request is received, only the following API actions are performed:
  - The `cors` preflow policy configures the appropriate response headers.
  - The response headers are set.
- When a preflight request is received, the `request.attributes.isCORSPreflight` flag is set to `true`.
- For all preflight requests, the `security` and `client-identification` preflow policies are always skipped, whether CORS is enabled or not enabled.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon.

Procedure

To enable CORS support for an API, complete the following steps:

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click CORS.
   The CORS page opens.
3. Select Enable CORS.
4. Optional: Configure a CORS policy.
   Should you create a CORS policy? Review the following considerations:
   - A CORS policy is an optional part of an API definition. If an API definition has no CORS policy but CORS is enabled, then CORS requests will be accepted from all Origins.
     If you want to accept CORS requests from all Origins, then enable CORS but do not add a CORS policy to the API definition.

- If you create a CORS policy, then CORS requests will only be accepted from Origins that are explicitly listed in the CORS rules contained in the CORS policy. CORS requests from any other Origins will be rejected.
  If you want to accept CORS requests from only a limited number of Origins (and might also want to configure the Access-Control-Allow-Credentials and Access-Control-Expose-Headers response headers), then you should enable CORS and create a CORS policy. Only those Origins explicitly listed in the allow-origin field of the CORS rules in the CORS policy will be accepted; CORS requests from any Origins not listed will be rejected.

- To configure a new CORS policy, complete the following steps:
  - Alongside CORS Policy, click Add.
  - To include the header **`Access-Control-Allow-Credentials: true`** in a response. select Allow Credentials. The **`Access-Control-Allow-Credentials`** response header tells browsers whether to expose the response to frontend JavaScript code when the request's credentials mode (**`Request.credentials`**) is set to **`include`**.
  - To append one or more of the following values to the **`Access-Control-Expose-Headers`** response header, select Expose headers, and select from the following options:
    - Predefined - The predefined value of the Gateway. This option is selected by default.
    - Backend - The value of **`Access-Control-Expose-Headers`** from the backend response.
    - Custom - A custom string.
  - Click Create.
  - Alongside Allowed Origins click Add.
  - Enter the origin URL, then click Create. This setting indicates that the response can be shared with requesting code from the specified origin.
- To modify an existing CORS policy, click its Allowed Origins entry on the CORS page. You can then modify individual origin URLs, add further origins, and change the Allow Credentials setting.

Example

The following example has three rules:

- Accept an Origin header of **`https://example.com`**, and return **`Access-Control-Allow-Credentials: true`** in the CORS response.
- Accept an Origin header of **`http://domain.com`**. No **`Access-Control-Allow-Credentials`** header will be returned in the response.
- Accept any of the following Origin headers:
  - **`http://example2.com`**
  - **`http://example3.com`**
  - **`http://example4.com`**

  No **`Access-Control-Allow-Credentials`** header will be returned in the response.

```
cors:
  enabled: true
  policy:
    -
      allow-origin:
        - 'https://example.com'
      allow-credentials: true
    -
      allow-origin:
        - 'http://domain.com'
    -
      allow-origin:
        - 'http://example2.com'
        - 'http://example3.com'
        - 'http://example4.com'
```

5. Click Save to save your changes.
6. Optional: To implement your own CORS solution using custom OPTIONS operations, complete the following steps:
   a. Add the following headers to your HTTP responses:

   ```
   Access-Control-Allow-Origin: https://<portalhostname>
   Access-Control-Allow-Headers: Origin, X-Requested-With, Content-Type, Accept
   ```

   Where `<portalhostname>` is your Developer Portal host name.
   b. Optional: You can proxy your API through API Connect as an enforced invoke API so that CORS is handled automatically.

Important:

- If you implement your own CORS solution, you **must** disable the CORS option described in step 3
- CORS preflight requests are sent by using the HTTP **`OPTIONS`** method. Therefore, if you require these requests to be handled by the API Connect gateway then you must enable the **`OPTIONS`** method for all APIs that will handle preflight requests; see Defining Paths for a REST API.
- **`OPTIONS`** requests are counted as API calls against any configured rate limit. Note that you can apply rate limits to individual operations; see Defining rate limits for an API operation.

Specifying external documentation for an API

You can reference an external resource for extended documentation for an API.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand the General section, then click External Documentation.
3. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
4. Click Save when done.

Adding tags to an API

You can include tags in API definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand the General then, if there already one or more tags defined, expand Tags.
3. To add a new tag, click the add icon ⊕ alongside Tags in the navigation pane. To edit an existing tag, click the tag name in the navigation pane.
4. Provide the following information:
   - Name (required): The name of the tag.
   - Description: An optional description of the tag. You can use CommonMark syntax for rich text representation.
   - External Documentation > URL (available when editing an existing tag): The URL for target documentation that describes this tag.
   - External Documentation > Description (available when editing an existing tag): An optional description of the target documentation.
5. If you are creating a new tag, click Create.
   The tag details are displayed for further editing as described in step 4.
6. Click Save when done.

Defining Paths for an API

A Path is a unit of a REST API that you can call. A Path comprises an HTTP verb and a URL path. By configuring the Path, you define how the API is exposed to your developers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The Path is appended to the server URL to form the full URL. For details on configuring servers, see Defining servers for an API.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. If there are already one or more Paths defined, expand Paths.
3. To create a new Path, click the add icon ⊕ alongside Paths in the navigation pane. To edit an existing Path, click the Path in the navigation pane.
4. Provide the following information:
   - Path: A relative path to an individual endpoint.
     The path is appended to the base path to construct the full URI to access the APIs. The path must start, but not end, with the / character. A parameter at the end of the path can contain a qualifier to match one or more path levels.

     If you specify just the name of the parameter, then one level of that path is matched. If you want to allow for multiple levels of the path, you can prefix the parameter with one of the following qualifiers:

- * to indicate 0 or more occurrences
- + to indicate 1 or more occurrences

The + and * qualifiers can only be used at the end of the path.

For example, the path:

```
/petstore/{type}/{*category}
```

matches the following paths, where only one type value is matched, but all (0 or more) categories are matched:

```
/petstore/cats
/petstore/cats/supplies
/petstore/cats/supplies/health
/petstore/cats/supplies/health/medicines
/petstore/cats/supplies/health/medicines/a/b/c
```

- Ref (available when editing an existing Path): A reference to a Path that is defined elsewhere, either in this OpenAPI definition, or in an external file. A reference enables reuse of a set of operations already defined for a Path in this API, or in a file that is either a complete API definition or an OpenAPI fragment.
  The reference uses JSON pointer notation. For example, a reference to a Path called `/mypath` in this API would have the following format:

  ```
  #/paths/~1mypath
  ```

  The `~1` characters are used to escape the `/` character, which is being used literally in the path name rather than as a special character.
  A reference to a path in an external file called path_fragments.yaml would have the following format:

  ```
  file://path_fragments.yaml/paths/~1mypath
  ```

- Summary: An optional summary, intended to apply to all operations in this path.
- Description: An optional description, intended to apply to all operations in this path. You can use CommonMark syntax for rich text representation.

5. If you are creating a new Path, click Create.
   The Path details are displayed for further editing as described in step 4.
6. Click Save when done.

- **Defining servers for a Path**
  Server definitions for a Path provide alternative target servers when calling the API at that Path.
- **Defining parameters for a Path**
  Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.
- **Defining operations for a Path**
  Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

Defining servers for a Path

Server definitions for a Path provide alternative target servers when calling the API at that Path.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: It is unlikely that you will need to define servers for a Path because it applies only if the API operations are distributed across different gateway endpoints, and such a configuration is possible only if you are hosting your API operations on your own runtime endpoints outside of API Connect. For an API that is published to the DataPower API Gateway, all API operations are invoked on the same gateway service.
A server defined for a Path overrides any server defined for the parent API. You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there already one or more servers defined for the Path, expand Servers.
4. To create a new server definition for the Path, click the add icon ⊕ alongside Servers under the Path in the navigation pane. To edit an existing server definition, click the server URL under the Path in the navigation pane.
5. Provide the following information:
   - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

     ```
     /my_basepath
     ```

     For full details on how the server URL is used to determine the full URL endpoint, see Configuring vanity endpoints for a Catalog.
   - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.

- Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
  - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
  - Provide the following information:
    - Server Variable Name (required).
    - Default value (required).
    - An optional rich text description. You can use CommonMark syntax for rich text representation.
    - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
  - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
  - If required, use the breadcrumb trail to return to your server definition for further editing.

6. If you are creating a new server definition, click Create.
   The path details are displayed for further editing as described in 5.
7. Click Save when done.

Defining parameters for a Path

Path parameters can specify variable elements of a URL path, query parameters, headers, or a request body. The parameters apply to all the operations defined under the path. A Path parameter can be overridden at the operation level but cannot be removed there.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there already one or more parameters defined, expand Parameters.
4. You can either create a new parameter, or edit any existing parameter.
   - To create a parameter, click the add icon ⊕ alongside Parameters, then refer to Creating a parameter.
   - To edit an existing parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining operations for a Path

Operations on a Path defines the mechanisms available for interacting with the API when it is called using that Path. An operation can be of various pre-defined types; for example, a POST operation is most commonly used for creating new resources, while a GET operation is used to retrieve a resource.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths.
3. Expand the required Path, then, if there are one or more operations, expand Operations.

4. To create an operation, click the add icon ⊕ alongside Operations under the Path in the navigation pane. To edit an existing operation, click the operation name under the Path in the navigation pane.
5. Provide the following information:
    - Verb: Select the operation type from the following options:
        - get
        - post
        - put
        - delete
        - options
        - head
        - patch
        - trace
    - Summary: A summary of what the operation does.
    - Description: A description of the operation behavior. You can use CommonMark syntax for rich text representation.
    - Operation ID: Unique string used to identify the operation. The id must be unique among all operations described in the API.
    - Deprecated: Declares this operation to be deprecated. Consumers should refrain from using the declared operation.
6. If you are creating a Path operation, click Create.
7. Click Save when done.

- **Adding tags to an operation**
  You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.
- **Specifying external documentation for an operation**
  You can referencing an external resource for extended documentation for an API operation.
- **Defining parameters for an operation**
  Operation parameters can, for the URL path associated with that specific operation, define variable elements of the URL path, query parameters, headers, or body parameters.
- **Defining the request body for an operation**
  A request body defines the structure of the body of an API request.
- **Defining responses for an operation**
  Responses define the HTTP status code and data returned in a response body and headers.
- **Enforcing security requirements on an operation**
  To enforce security requirements on an API operation, you apply previously created security scheme components that define various aspects of API security configuration.
- **Defining servers for an operation**
  Server definitions for an API operation provide alternative target servers when calling that operation.

Adding tags to an operation

You can include tags in API operation definition. Such tags are added to the OpenAPI definition of the API but are not used by API Connect for any indexing.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To add a new operation tag, click the add icon ⊕ alongside the Tags entry for the operation in the navigation pane. To edit an existing tag, expand Tags then click the tag name in the navigation pane.
5. Provide the following information:
    - Name (required): The name of the tag.
6. If you are creating a new operation tag, click Create.
   The tag details are displayed for further editing as described in step 5.
7. Click Save when done.

Specifying external documentation for an operation

You can referencing an external resource for extended documentation for an API operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click External Documentation.
4. Provide the following information:
   - URL (required): The URL for the target documentation.
   - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
5. Click Save when done.

Defining parameters for an operation

Operation parameters can, for the URL path associated with that specific operation, define variable elements of the URL path, query parameters, headers, or body parameters.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An operation parameter overrides a parameter of the same name defined on the parent Path; see Defining parameters for a Path.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. You can either create a new operation parameter, or edit any existing parameter.
   - To create an operation parameter, click the add icon alongside Parameter, then refer to Creating a parameter.
   - To edit an existing operation parameter, click the parameter name in the navigation pane, then refer to Editing a parameter.

Defining the request body for an operation

A request body defines the structure of the body of an API request.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Note: The user interface doesn't currently support referencing a request body component from an operation. However, you can add the reference directly to the OpenAPI YAML source for your API definition, for example:

```
paths:
  /mypath:
    get:
          .
          .
          .
      requestBody:
        $ref: '#/components/requestBodies/my_requestbody_component'
          .
          .
          .
```

For information on request body components, see Defining request body components.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then click requestBody.
4. Provide the following information:
   - Description: An optional description of the request body. This could contain examples of use. You can use CommonMark syntax for rich text representation.
   - Content: A content definition describes the content of the request body.
     To define a new content definition for the request body, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.
   - Required: Determines if the request body is required in the request.
5. Click Save when done.

Defining responses for an operation

Responses define the HTTP status code and data returned in a response body and headers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there are any existing responses, expand Responses.
4. You can either create a new response, or edit any existing response.
   - To create a response, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response, click the response name in the navigation pane, then refer to Editing a response.

Enforcing security requirements on an operation

To enforce security requirements on an API operation, you apply previously created security scheme components that define various aspects of API security configuration.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

For details on how to create and configure security scheme components, see Defining security scheme components.

A security requirement specifies one or more security scheme components whose conditions must all be satisfied for the API operation to be called successfully. You can define multiple security requirements; in this case, an application can call your API operation if it satisfies any of the security requirements you have defined.

Any security requirements that you define for an operation completely override any security requirements defined on the parent API. If you do not define any security requirements for an operation, or you delete all security requirements from an operation, the operation inherits the security requirements defined on the parent API. For more information, see Enforcing security requirements on an API.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, then expand the required operation.
4. To create a new security requirement for the operation, complete the following steps:
   a. Click the add icon ⊕ alongside the Security Requirements entry for the operation in the navigation pane.
   b. Select the security schemes that you want to include in this security requirement. The security schemes listed are those that have been defined in security scheme components; see Defining security scheme components.
   If a selected security scheme is of type OAuth2, select the required scopes; the scopes available for selection are those that were specified in the security scheme component; for more information, see Defining OAuth2 security scheme components.

   If you are applying the OAuth2 security scheme to an API that is enforced by the DataPower API Gateway, you only need select any scopes if Advanced scope check after token generation is not enabled in the native OAuth provider associated with the security scheme. If a default scope has been set in the native OAuth provider and the API request doesn't contain any scope, the default scope is used; for more information, see Configuring scopes for a native OAuth provider.

   Note: The following additional requirement applies to security schemes that will be used with an OAuth third party provider. If you select an OAuth security scheme for protecting a consumer API, you must also include an API key security scheme, as the `X-IBM-Client-Id` or `client_id` must be included in the security credentials so that the correct Plan configuration settings can be enforced.
   c. Click Create. The security scheme selections are shown; you can change them again before saving.
   d. Click Submit when done.
5. To modify an existing security requirement, complete the following steps:
   a. Click the Security entry for the operation in the navigation pane. All previously defined security requirements are listed; the security schemes included in each security requirement are shown.
   b. To change the security schemes for a security requirement, click the edit icon alongside the required security requirement, then change your security requirement selections as required.
   c. Click Submit when done, then click Save.
   d. To delete a security requirement, click the appropriate delete icon , click Delete to confirm, then click Save.
   e. To disable security for the operation, clear the Require one of the following Security Requirements check box, then click Save.

Note: These settings completely override any security requirements defined on the parent API; see Enforcing security requirements on an API.

Defining servers for an operation

Server definitions for an API operation provide alternative target servers when calling that operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A server defined for an operation overrides any server defined for the parent API or Path. You can define more than one server but only the first is used by API Connect.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Paths, then expand the required Path.
3. Expand Operations, expand the required operation, then, if there already one or more servers defined for the operation, expand Servers.
4. To create a new server definition for the operation, click the add icon ⊕ alongside Servers under the operation in the navigation pane. To edit an existing server definition, click the server URL under the operation in the navigation pane.
5. Provide the following information:
   - Server URL (required): The specified URL is used to determine the full URL endpoint for the calling the API, taking into account any vanity endpoint configuration in the Catalog in which the API is published. For an API that is enforced by the DataPower API Gateway, the value entered here is interpreted as the basepath so you would typically provide only the basepath value; for example:

     `/my_basepath`

     For full details on how the server URL is used to determine the full URL endpoint, see Configuring vanity endpoints for a Catalog.
   - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
   - Server Variables (available when editing an existing server definition): A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
     - To add a new server variable, click Add. To edit an existing server variable, click the variable name.

- Provide the following information:
  - Server Variable Name (required).
  - Default value (required).
  - An optional rich text description. You can use CommonMark syntax for rich text representation.
  - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
- If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
- If required, use the breadcrumb trail to return to your server definition for further editing.

6. If you are creating a new server definition, click Create.
   The path details are displayed for further editing as described in 5.
7. Click Save when done.

Defining components for an API

Components are reusable objects relating to various aspects of your API definition. A component has no effect on the API unless it is explicitly referenced from elsewhere in your API definition.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The following subtopics detail the various types of API component:

- **Defining schema components**
  Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.
- **Defining response components**
  Response components define reusable response objects that specify the HTTP status code and data returned in a response body and headers.
- **Defining parameter components**
  Parameter components define reusable parameters that can specify variable elements of a URL path, query parameters, headers, or a request body.
- **Defining example components**
  An example component is a reusable example that you can add to an API to make the specification of your API clearer.
- **Defining request body components**
  A request body component is a reusable definition of the structure of the body of an API request.
- **Defining header components**
  A header component defines a reusable custom header that can be sent in an API request or returned in an API response.
- **Defining security scheme components**
  A security scheme component specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.
- **Defining link components**
  A link component is a reusable link definition that can be used to describe how various values returned by one operation can be used as input for other operations. In this way, links provide a known relationship and traversal mechanism between the operations.

Defining schema components

Schema components define reusable schemas that provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

An API created in OpenAPI 3.0 includes a section where API payload definitions are defined. The payload definitions describe the structure of data transmitted in API requests and responses, utilizing a specialized JSON schema variant specific to OpenAPI. Each payload definition corresponds to a schema, which lists the expected data fields. These data fields are represented as properties within the schema and include a set of attributes that describe their type, permissible values, mandatory status, and other characteristics. Although numerous attributes are available, the majority of them are infrequently utilized.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a schema component, you reference it from elsewhere in your API definition. You can reference a schema from the following locations:

- An API Path parameter; see Defining parameters for a Path.
- An API operation parameter; see Defining parameters for an operation.
- The request body of an API operation; see Defining the request body for an operation.
- An API operation response; see Defining responses for an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more schemas components defined, expand Schemas.
3. You can create a new schema component, or edit any existing schema component.
   - To create a schema component, click the add icon alongside Schemas, then refer to Creating a schema component.
   - To edit an existing schema component, click the schema component name in the navigation pane, then refer to Editing a schema component.

- **Creating a schema component**
  Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.
- **Editing a schema component**
  Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Creating a schema component

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can create schemas in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
Launch the schema creation window. For details of the areas in your API definition from where you can create a schema, see the following topics:

- Editing a content definition
- Editing a header
- Editing a parameter
- Defining schema components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. To create a schema definition, open the Componentselement and click the add icon alongside Schema.
   The Add object wizard for a schema is displayed.
2. Provide the following information:
   -
     - Schema Name: If you are creating a schema component, this name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/schemas/Name`

     - Title: The schema title.
     - Type: The schema data type; select one of the following:
       - array
       - boolean
       - integer
       - number
       - object
       - string
3. Click Create.
   The schema details are displayed for further editing; see Editing a schema component.

Editing a schema component

Schemas provide developers with information about the request they should make, or the response they should expect to receive, when calling an API operation. You can edit schemas that have been previously created in various places in your API definition.

Before you begin

Note: Schemas are compiled before they are used for validation. Because the compilation process is longer than the validation process, the compiled schema artifacts are stored in a cache. The limited capacity of the cache can cause older entries to be evicted from the cache when newer entries are added. Schemas whose artifacts have been evicted from the cache must be recompiled, which can cause significant delays in validation.
Open the details form for a schema. For details of the areas in your API definition from where you can edit a schema, see the following topics:

- Editing a content definition
- Editing a header
- Editing a parameter
- Defining schema components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The table view presents the properties within a schema alongside their essential attributes, such as name, type, description, and required status. The secondary pop-up enables access for viewing and editing the more detailed and less commonly used attributes that are associated with each data field.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

You can configure the following schema settings:

- Schema Name: Available if you are editing a schema component, this name defines a key that enables this schema to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/components/schemas/`*`Name`*

  To change the name, click the Source icon, change the value in the field, then click Save
- Optional: Title: The schema title.
- Optional: Type: The schema data type; select one of the following:
  -
    - array
    - boolean
    - integer
    - number
    - object
    - string

  Note: If you change the type of an existing schema, any existing settings that are not relevant to the new type are still retained in the OpenAPI source even though they are no longer displayed in the user interface. You should therefore avoid porting a schema from one type to another but instead either create a new schema or modify the OpenAPI source directly; to open the source editor, click the Source icon </> .
- Properties: The schema property. To add a property to the schema, click Add alongside the Properties section heading, complete the details and click Save.
- Additional schema settings dependent on the selected Type of property. To view and edit these schema settings, click the Options menu next to the property you want to view and select Details.
  - boolean: no type specific settings.
  - integer:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of an integer instance by this value must result in an integer.
    - Maximum: An integer instance must be less than or equal to this value.
    - Exclusive Maximum: An integer instance must be strictly less than this value.
    - Minimum: An integer instance must be greater than or equal to this value.
    - Exclusive Minimum: An integer instance must be strictly greater than this value.
  - number:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Multiple Of: Division of a number instance by this value must result in an integer.
    - Maximum: A number instance must be less than or equal to this value.
    - Exclusive Maximum: A number instance must be strictly less than this value.
    - Minimum: A number instance must be greater than or equal to this value.
    - Exclusive Minimum: A number instance must be strictly greater than this value.
  - object:
    - Max Properties: The number of properties in an object instance must be less than or equal to this value.
    - Min Properties: The number of properties in an object instance must be greater than or equal to this value.
    - Required Properties: An array of property names; every property name in the array must be the name of a property in an object instance. To add a required property name, click Add alongside the Required Properties section heading, enter the name, then click Create.
  - string:
    - Format: An optional data type modifier. For more information, see Data Types in the OpenAPI Specification.
    - Pattern: A regular expression; a string instance must successfully match the expression.
    - Max Length: The maximum allowed number of characters in a string instance.
    - Min Length: The minimum allowed number of characters in a string instance.
    - Enum: An array of string values; a string instance must match one of the array values. To add an enum value, click Add, enter the value, then click Create.

- General settings; select the required options:
  - Required: A property associated with this schema is required.
  - Read Only: A property associated with this schema can be returned in a response but should not be included in a request. For example, properties whose values are system generated identifiers will be defined as Read Only because application clients wouldn't be able to set these.
- Example Value: An example value. Whatever you enter here is displayed as-is in the Developer Portal.
- External Documentation: An external resource for extended documentation; provide the following information:
  - URL (required): The URL for the target documentation.
  - Description: An optional description of the target documentation. You can use CommonMark syntax for rich text representation.
- Xml: Metadata that allows for more fine-tuned XML model definitions; provide the following information:
  - Name: Replaces the name of the element or attribute used for the described schema property.
  - Namespace: The URL of the namespace definition.
  - Prefix: The prefix to be used for the Name.
  - Attribute: Specifies whether the property definition translates to an attribute instead of an element.
  - Wrapped: For an array definition, Specifies whether the array is wrapped (for example, `<books><book/><book/></books>`) or unwrapped (`<book/> <book/>`).
- Click Save when done.

Example

By defining properties, you can create more complex data structures. For example, you could define an "Address" schema that has the following properties:

PROPERTY NAME	PROPERTY TYPE
street1	string
street2	string
city	string
state	string
zip_code	string

and then define a "BankBranch" schema that has the following properties, one of which is a reference to the Address schema:

PROPERTY NAME	PROPERTY TYPE
address	address
type	string
id	string

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining response components

Response components define reusable response objects that specify the HTTP status code and data returned in a response body and headers.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a response component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more response components defined, expand Responses.
3. You can create a new response component, or edit any existing response component.
   - To create a response component, click the add icon ⊕ alongside Responses, then refer to Creating a response.
   - To edit an existing response component, click the response component name in the navigation pane, then refer to Editing a response.

- **Creating a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.
- **Editing a response**
  Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.
- **Creating a content definition**
  A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.
- **Editing a content definition**
  A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.
- **Creating an encoding definition**
  An encoding definition defines a map between a specific schema property and its encoding information.

- **Editing an encoding definition**
  An encoding definition defines a map between a specific schema property and its encoding information

Creating a response

Responses define the HTTP status code and data returned in a response body and headers. You can create responses for the Path operations in your API definition.

Before you begin

Launch the response creation window. For details of the areas in your API definition from where you can create a response, see the following topics:

- Defining responses for an operation
- Defining response components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon  . To return to the design form, click the Form icon  .

Procedure

1. Create the response; you can either create a response from scratch, or you can reference a response that is defined in a response component.
   - To create the response from scratch, provide the following information on the Definition tab:
     - Response name: A name for the response.
       If you are creating an operation response, this name is the HTTP status code.

       If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/responses/Name`

     - Description (required): A description of the response. You can use CommonMark syntax for rich text representation.
   - To reference a response that is defined in a response component, provide the following information on the Reference tab:
     - Response name: A name for the response.
       If you are creating an operation response, this name is the HTTP status code.

       If you are creating a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/responses/Name`

     - Reference from: Select a reference to a response component.
2. Click Create.
   The response details are displayed for further editing; see Editing a response.

Editing a response

Responses define the HTTP status code and data returned in a response body and headers. You can edit responses that have been previously created for Path operations in your API definition.

Before you begin

Open the details form for a response. For details of the areas in your API definition from where you can edit a response, see the following topics:

- Defining responses for an operation
- Defining response components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Response name: A name for the response.
     If you are editing an operation response, this name is the HTTP status code.

     If you are editing a response component, this name defines a key that enables this response to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/responses/Name`

     To change the name, click Update, then click Save when done.

   - Description: A description of the response. You can use CommonMark syntax for rich text representation.
   - Headers: Headers define information that can be returned in the response.
     To define a new header for the response, click Add, then refer to Creating a header.

     To edit an existing header, click the header name, then refer to Editing a header.

   - Content: A content definition describes the content of the response.
     To define a new content definition for the response, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

   - Links: Links describe how various values returned by one operation can be used as input for other operations.
     To define a new link for the response, click Add, then refer to Creating a link.

     To edit an existing link, click the link name, then refer to Editing a link.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating a content definition

A content definition describes the content of an API request, response, or parameter. You can create content definitions in various places in your API definition.

Before you begin

Launch the content definition creation window. For details of the areas in your API definition from where you can create a content definition, see the following topics:

- Editing a header
- Editing a request body
- Defining the request body for an operation
- Editing a response

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Content Type: Select the content type; for example, application/json.
     Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a media type range; for example, `text/*`, `*/json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable;. for example, `text/plain` overrides `text/*`.
2. Click Create.
   The content definition details are displayed for further editing; see Editing a content definition.

Editing a content definition

A content definition describes the content of an API request, response, or parameter. You can edit content definitions that have been previously created in various places in your API definition.

Before you begin

Open the details form for a content definition. For details of the areas in your API definition from where you can edit a content definition, see the following topics:

- Editing a header
- Editing a request body
- Defining the request body for an operation
- Editing a response

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Content Type: Select the content type; for example, application/json.
     Note: While the Content Type field in the editor provides a selection list of media types, by editing the OpenAPI source for the API directly you can specify a media type range; for example, `text/*`, `*/json`, or `*/*`. For requests or responses that match multiple types, only the most specific type is applicable;. for example, `text/plain` overrides `text/*`.
   - Schema:
     To define a schema for the content definition, click Create, then refer to Creating a schema component.

     If the content definition already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing a schema component.
     Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
   - Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.
   - Examples:
     To add an example of the content, click Add, then refer to Creating an example.

     To edit an existing example, click the example name, then refer to Editing an example.

   - Encoding: An encoding definition describes how a specific schema property is encoded.
     To add an encoding definition, click Add, then refer to Creating an encoding definition.

     To edit an existing encoding definition, click the name, then refer to Editing an encoding definition.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Creating an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information.

Before you begin

Launch the encoding definition creation window when configuring a content definition; see Editing a content definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The name of the schema property.
   - Content Type: The Content-Type for encoding the property; for example, **`application/xml; charset=utf-8`**, **`image/png, image/jpeg`**.
   - Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
     - form: Form style properties defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form properties.
   - Explode: When selected, property values of type **`array`** or **`object`** generate separate properties for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the property value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding.
2. Click Create.
   The encoding definition details are displayed for further editing; see Editing an encoding definition.

Editing an encoding definition

An encoding definition defines a map between a specific schema property and its encoding information

Before you begin

Open the details form for an encoding definition when configuring a content definition; see Editing a content definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: The name of the schema property. To change the name, click Update, then click Save when done.
   - Content Type: The Content-Type for encoding the property; for example:
     - **`application/xml; charset=utf-8`**
     - **`image/png, image/jpeg`**.
   - Headers: A map allowing additional information to be provided as headers.
     To add a new header, click Add, then refer to Creating a header.

     To edit an existing header, click the header name, then refer to Editing a header.
   - Style: Describes how the property value will be serialized depending on the type of the property value. Select one of the following options:
     - form: Form style properties defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form properties.
   - Explode: When selected, property values of type **`array`** or **`object`** generate separate properties for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the property value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining parameter components

Parameter components define reusable parameters that can specify variable elements of a URL path, query parameters, headers, or a request body.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a parameter component, you must reference it from elsewhere in your API definition.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more parameter components defined, expand Parameters.
3. You can create a new parameter component, or edit any existing parameter component.
   - To create a parameter component, click the add icon ⊕ alongside Parameters, then refer to Creating a parameter.
   - To edit an existing parameter component, click the parameter component name in the navigation pane, then refer to Editing a parameter.

- **Creating a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.
- **Editing a parameter**
  Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Creating a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can create parameters for Paths and Path operations in your API definition.

Before you begin

Launch the parameter creation window. For details of the areas in your API definition from where you can create a parameter, see the following topics:

- Defining parameters for a Path
- Defining parameters for an operation
- Defining parameter components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the parameter; you can either create a parameter from scratch, or you can reference a parameter that is defined in a parameter component.
   - To create the parameter from scratch, provide the following information on the Definition tab:

- Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

  `#/components/parameters/Name`

  Note: When the name of a query parameter includes the "+" special character, it is encoded as %2B (literal plus character) instead of %20 (literal space character). Therefore, to match the query parameter against the inbound URL, the encoded value is used. For example, when the name of the query parameter is a+space, the value to match in the inbound URL is a%2Bspace.
- Parameter name (required): The name of the parameter.
- Located In (required): The location of the parameter. Select one of the following options:
  - query: Parameters that are appended to the URL. For example, `url_path?myparam=myvalue`.
  - header: Custom headers that are expected as part of the request.
  - path: The parameter value is part of the operation's URL, enclosed in {}.
  - cookie: Used to pass a specific cookie value to the API.
- Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
- Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
  - matrix: Path-style parameters defined by RFC 6570.
  - label: Label style parameters defined by RFC 6570.
  - simple: Simple style parameters defined by RFC 6570.
  - form: Form style parameters defined by RFC 6570.
  - spaceDelimited: Space separated array values.
  - pipeDelimited: Pipe separated array values.
  - deepObject: Provides a simple way of rendering nested objects using form parameters.
- Select the following options as required:
  - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
  - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
  - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
  - Explode: When selected, parameter values of type `array` or `object` generate separate parameters for each value of the array or key-value pair of the map.
  - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by RFC 3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding. This property applies only if the Located In property is set to query.

- To reference a parameter that is defined in a parameter component, provide the following information on the Reference tab:
  - Name: Available if you are creating a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

    `#/components/parameters/Name`

    Note: When the name of a query parameter includes the "+" special character, it is encoded as %2B (literal plus character) instead of %20 (literal space character). Therefore, to match the query parameter against the inbound URL, the encoded value is used. For example, when the name of the query parameter is a+space, the value to match in the inbound URL is a%2Bspace.
  - Parameter name (required, available if you are creating a path or operation parameter): The name of the parameter.
  - Reference from: Select a reference to a parameter component.

2. Click Create.
   The parameter details are displayed for further editing; see Editing a parameter.

Editing a parameter

Parameters define variable elements of a URL path, query parameters, headers, or a request body. You can edit parameters that have been previously created for Paths and Path operations in your API definition.

Before you begin

Open the details form for a parameter. For details of the areas in your API definition from where you can edit a parameter, see the following topics:

- Defining parameters for a Path
- Defining parameters for an operation
- Defining parameter components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A parameter is similar to a header, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to `header`.
- A parameter can have various format styles, the style of a header is always `simple`.

For more information on headers, see Creating a header.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: Available if you are editing a parameter component, this name defines a key that enables this parameter to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/parameters/Name`

     To change the name, click Update, then click Save when done.
   - Parameter name (required): The name of the parameter.
   - Located In (required): The location of the parameter. Select one of the following options:
     - query: Parameters that are appended to the URL. For example, `url_path?myparam=myvalue`.
     - header: Custom headers that are expected as part of the request.
     - path: The parameter value is part of the operation's URL, enclosed in {}.
     - cookie: Used to pass a specific cookie value to the API.
   - Description: A description of the parameter. You can use CommonMark syntax for rich text representation.
   - Style: Describes how the parameter value will be serialized depending on the type of the parameter value. Select one of the following options:
     - matrix: Path-style parameters defined by RFC6570.
     - label: Label style parameters defined by RFC6570.
     - simple: Simple style parameters defined by RFC6570.
     - form: Form style parameters defined by RFC6570.
     - spaceDelimited: Space separated array values.
     - pipeDelimited: Pipe separated array values.
     - deepObject: Provides a simple way of rendering nested objects using form parameters.
   - Select the following options as required:
     - Required: Determines whether this parameter is mandatory. If the Located In property is set to path, this option must be selected.
     - Deprecated: Specifies that a parameter is deprecated and should be transitioned out of usage.
     - Allows Empty Value: Allows sending a parameter with an empty value. This is valid only if the Located In property is set to query.
     - Explode: When selected, parameter values of type `array` or `object` generate separate parameters for each value of the array or key-value pair of the map.
     - Allow Reserved: Determines whether the parameter value should allow reserved characters, as defined by RFC3986 (`:/?#[]@!$&'()*+,;=`) to be included without percent-encoding. This property applies only if the Located In property is set to query.
   - Schema:
     To define a schema for the parameter, click Create, then refer to Creating a schema component.

     If the parameter already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing a schema component.
     Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
   - Example Value: An example of a parameter value. Whatever you enter here is displayed as-is in the Developer Portal.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining example components

An example component is a reusable example that you can add to an API to make the specification of your API clearer.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an example component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more example components defined, expand Examples.
3. You can create a new example component, or edit any existing example component.
   - To create an example component, click the add icon ⊕ alongside Examples, then refer to Creating an example.
   - To edit an existing example component, click the example component name in the navigation pane, then refer to Editing an example.

- **Creating an example**
  You add examples to an API to make the specification of your API clearer.
- **Editing an example**
  You add examples to an API to make the specification of your API clearer.

Creating an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Launch the example creation window. For details of the areas in your API definition from where you can create an example, see the following topics:

- Editing a content definition
- Defining example components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the example; you can either create an example from scratch, or you can reference an example that is defined in an example component.
   - To create the example from scratch, provide the following information on the Definition tab:
     - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

     - Summary: A summary description of the example.
     - Description: A full description of the example. You can use CommonMark syntax for rich text representation.
     - External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could a PDF, for example.
   - To reference an example that is defined in an example component, provide the following information on the Reference tab:
     - Example Name: If you are creating an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

     - Reference from: Select a reference to an example component.
2. Click Create.
   The example details are displayed for further editing; see Editing an example.

Editing an example

You add examples to an API to make the specification of your API clearer.

Before you begin

Open the details form for an example. For details of the areas in your API definition from where you can edit an example, see the following topics:

- Editing a content definition
- Defining example components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   -
     - Example Name: If you are editing an example component, this name defines a key that enables this example to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/examples/Name`

       To change the name, click Update, then click Save when done.
     - Summary: A summary description of the example.
     - Description: A full description of the example. You can use CommonMark syntax for rich text representation.
     - Example Value: A literal example.
     - External Value: A URL that points to a literal example. This provides the capability to reference examples that cannot easily be included in JSON or YAML documents. This could a PDF, for example.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining request body components

A request body component is a reusable definition of the structure of the body of an API request.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more request body components defined, expand Request Bodies.
3. You can create a new request body component, or edit any existing request body component.
   - To create a request body component, click the add icon alongside Request Bodies, then refer to Creating a request body.
   - To edit an existing request body component, click the request body component name in the navigation pane, then refer to Editing a request body.

- **Creating a request body**
  A request body defines the structure of the body of an API request.
- **Editing a request body**
  A request body defines the structure of the body of an API request.

Creating a request body

A request body defines the structure of the body of an API request.

Before you begin

Launch the request body creation window; see Defining request body components.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Create the request body; you can either create a request body from scratch, or you can reference a request body that is defined in a request body component.
   - To create the request body from scratch, provide the following information on the Definition tab:
     - Name: A name for the request body.
       If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/requestBodies/Name`

     - Description: A description of the request body. You can use CommonMark syntax for rich text representation.
     - Required: Determines if the request body is required in the request.
   - To reference a request body that is defined in a request body component, provide the following information on the Reference tab:
     - Name: A name for the request body.
       If you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/requestBodies/Name`

     - Reference from: Select a reference to a request body component.
2. Click Create.
   The request body details are displayed for further editing; see Editing a request body.

Editing a request body

A request body defines the structure of the body of an API request.

Before you begin

Open the details form for a request body; see Defining request body components.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: A name for the request body.
     Available if you are creating a request body component, this name defines a key that enables this request body to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/requestBodies/Name`

   - Description: A description of the request body. You can use CommonMark syntax for rich text representation.
   - Content: A content definition describes the content of the request body.
     To define a new content definition for the request body, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

   - Required: Determines if the request body is required in the request.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining header components

A header component defines a reusable custom header that can be sent in an API request or returned in an API response.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a header component, you must reference it from elsewhere in your API definition.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more header components defined, expand Headers.
3. You can create a new header component, or edit any existing header component.
   - To create a header component, click the add icon ⊕ alongside Headers, then refer to Creating a header.
   - To edit an existing header component, click the header component name in the navigation pane, then refer to Editing a header.

- **Creating a header**
  A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.
- **Editing a header**
  A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Creating a header

A header defines information that can be sent in an API request or returned in an API response. You can create headers in various places in your API definition.

Before you begin

Launch the header creation window. For details of the areas in your API definition from where you can create a header, see the following topics:

- Editing a response
- Editing an encoding definition
- Defining header components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the header; you can either create a header from scratch, or you can reference a header that is defined in a header component.
   - To create the header from scratch, provide the following information on the Definition tab:
     - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/headers/`*`Name`*

     - Description: A description of the header. You can use CommonMark syntax for rich text representation.
     - Required: Determines whether this header is mandatory.
     - Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.

- Allow Empty Value: The header can be sent with an empty value.
- Explode: When selected, header values of type **`array`** or **`object`** generate separate headers for each value of the array or key-value pair of the map.
- Allow Reserved: Determines whether the header value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding.

- To reference a header that is defined in a header component, provide the following information on the Reference tab:.
  - Header name: If you are creating a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

    `#/components/headers/`*`Name`*

  - Reference from: Select a reference to a header component.

2. Click Create.
   The header details are displayed for further editing; see Editing a header.

Editing a header

A header defines information that can be sent in an API request or returned in an API response. You can edit headers that have been previously created in various places in your API definition.

Before you begin

Open the details form for a header. For details of the areas in your API definition from where you can edit a header, see the following topics:

- Editing a response
- Editing an encoding definition
- Defining header components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

A header is similar to a parameter, with the following differences:

- Parameters carry actual data and are available to end users, headers carry meta data associated with a request or response and are hidden from end users.
- A parameter can have various locations, the location of a header is always set to **`header`**.
- A parameter can have various format styles, the style of a header is always **`simple`**.

For more information on parameters, see Creating a parameter.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Header name: If you are editing a header component, this name defines a key that enables this header to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/headers/`*`Name`*

     To change the name, click Update, then click Save when done.
   - Description: A description of the header. You can use CommonMark syntax for rich text representation.
   - Required: Determines whether this header is mandatory.
   - Deprecated: Specifies that this header is deprecated and should be transitioned out of usage.
   - Allow Empty Value: The header can be sent with an empty value.
   - Explode: When selected, header values of type **`array`** or **`object`** generate separate headers for each value of the array or key-value pair of the map.
   - Allow Reserved: Determines whether the header value should allow reserved characters, as defined by RFC3986 (**`:/?#[]@!$&'()*+,;=`**) to be included without percent-encoding.
   - Schema:
     To define a schema for the header, click Create, then refer to Creating a schema component.

     If the header already has a schema defined, click View to edit the schema.

     For full details on editing a schema, see Editing a schema component.
     Note: You cannot edit the schema if it references a schema component, the schema configuration is inherited from the schema component; for details on configuring a schema component, see Defining schema components. You can, however, edit the referenced schema component but any changes will be reflected anywhere that the schema component is referenced.
   - Content: A content definition describes the content of the header.
     To define a new content definition for the header, click Add, then refer to Creating a content definition.

     To edit an existing content definition, click the content definition name, then refer to Editing a content definition.

2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Defining security scheme components

A security scheme component specifies all the settings for a particular aspect of API security; for example, the user registry that you use to authenticate access to the API.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can create security definitions of the following types:

Type	Description
Basic authentication	Use a basic authentication security definition to specify a user registry or an authentication URL to be used to authenticate access to the API.
API key	Use an API key security definition to specify what application credentials are required to call an API.
OAuth2	Use an OAuth2 security definition to specify settings for OAuth token based authentication for your API.
HTTP Bearer	Use an HTTP Bearer definition to specify how to validate the Bearer token that is required to call an API.

- **Defining basic authentication security scheme components**
  A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.
- **Defining API key security scheme components**
  An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.
- **Defining OAuth2 security scheme components**
  An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.
- **Defining OIDC security scheme components**
  An OIDC (OpenID Connect) security scheme defines settings for using your OIDC provider to control access to the API.
- **Defining an HTTP bearer security scheme**
  An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

Defining basic authentication security scheme components

A basic authentication security scheme component is used when an application that calls the API is required to authenticate through a user registry.

Before you begin

For authenticating access to the operations of APIs that are enforced on the API Connect gateway, the following user registry types are supported:

- Authentication URL
- LDAP

The following user registry types are **not** supported:

- OpenID Connect (OIDC)
- Local User Registry (LUR)
- A custom user registry

Before you can create a basic authentication security definition in an API, the user registry must exist. To create a user registry, you can use either API Manager or Cloud Manager. When you create a registry in API Manager, it is visible only to your provider organization. When you create a registry in Cloud Manager, you can make it visible to multiple provider organizations.

To create a user registry with API Manager, see Working with user registries.

To create a user registry with Cloud Manager, see User registries overview.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you use basic authentication, you require API users to provide a valid user name and password to access selected operations. The application developer must also provide an HTTP authorization header in requests that are sent to operations that require basic authentication.

When you use an authentication URL, the user credentials that are provided in the authorization header are validated by the endpoint specified in the URL. If the user is authenticated, IBM API Connect expects an authentication URL to return an HTTP `200 OK` response status code. All other HTTP response status codes result in an authentication failure and access is denied.

For more information about using an LDAP user registry for authentication, see LDAP authentication.

For information about using an Authentication URL, see Authentication URL user registry.

To make use of a basic authentication security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create a basic authentication security scheme component, click the add icon alongside Security Schemes. To edit an existing basic authentication security scheme component, click the component name in the navigation pane.
4. If you are creating a new basic authentication security scheme component, you can either create it from scratch or you can reference another basic authentication security scheme component.
   To create a basic authentication security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Security Scheme Type (required): Select http.
   - Scheme (required): The name of the HTTP Authorization scheme to be used in the Authorization header as defined in RFC7235.
   - Authenticate using User Registry: The name of the user registry to be used for authentication. This is the value of the **name** field that was auto-generated when the user registry was created.
   - Bearer format: A hint to the client to identify how the bearer token is formatted. Bearer tokens are usually generated by an authorization server, so this information is primarily for documentation purposes.
   - Description: An optional description of the basic authentication security scheme. You can use CommonMark syntax for rich text representation.

   To reference another basic authentication security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name (required): A key that enables this basic authentication security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Reference from: Select a reference to another basic authentication security scheme component.
5. If you are creating a new basic authentication security scheme component, click Create.
   The security scheme component details are displayed for further editing.
6. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Fore more information on LDAP and Authentication URL, see LDAP authentication and Authentication URL user registry.

Defining API key security scheme components

An API key security component is used to specify the credentials that an application must provide to identify itself when calling the API operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can require that, when calling an API operation, an application must provide either a client ID, or a client ID and client secret; you create an API key security scheme component to specify a credentials requirement. If you require that an application must provide both a client ID and client secret, you must create two API key security scheme components, one for each type of credentials.

To make use of an API key security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create an API key security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an API key existing security scheme component, click the component name in the navigation pane.
4. If you are creating a new API key security scheme component, you can either create it from scratch or you can reference another API key security scheme component.
   To create an API key security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Security Scheme Type: Select apiKey.
   - Name: The name of the header, query or cookie parameter to be used. For a key of type client secret you must include the string "secret", ignoring case, in the value you specify in the Name field; if the value does not contain the string "secret" then the key is assumed to be of type client ID.
     Note: The client ID and client secret headers that are specified in the request when the API is called are **not** added automatically to the message context. If you need these headers in the message context for subsequent processing, include a `set-variable` policy in your API assembly that adds the headers to the message content, taking the values specified in the request; you can do this in either of the following ways:
     - In the Assemble tab, add a Set Variable policy to your API assembly that defines the appropriate actions; for example:

       Table 1.

Action	Set	Type	Value
Set	message.headers.X-IBM-Client-Id	string	$(request.headers.X-IBM-Client-Id)
Set	message.headers.X-IBM-Client-Secret	string	$(request.headers.X-IBM-Client-Secret)

       For more information on configuring a Set Variable policy, see Set Variable.
     - In the Source tab, add a `set-variable` policy directly to the assembly section in your OpenAPI source; for example:

```
assembly:
  execute:
    - set-variable:
        version: 2.0.0
        title: set-variable
        actions:
          - set: message.headers.X-IBM-Client-Id
            value: $(request.headers.X-IBM-Client-Id)
            type: string
          - set: message.headers.X-IBM-Client-Secret
            value: $(request.headers.X-IBM-Client-Secret)
            type: string
```

       For more information on defining a `set-variable` policy in your OpenAPI source, see set-variable.
     You should position the `set-variable` before any policy that needs to access the API key headers; for example, an invoke policy that calls a back-end service that is required to identify the application that made the initial request.
   - Key Type: Select client_id or client_secret.
     Important: The client_id is not confidential and functions as a "SecurityScheme" only in the meaning of the OpenAPI specification.
     If you use only the client_id (without the client_secret) as your API Key, be aware that the client_id is not considered a confidential value in the API Manager UI; for example, it might be displayed to other authenticated members of the provider organization. The client_id is treated as a public identifier for apps and cannot be kept private.

     If authentication of the identity of the app calling an API is needed, then the API Key should use both a client_id to identify the app, plus a client_secret to authenticate it. The client_secret is designed to be known only to the app and the authorization server, and it should be protected. IBM API Connect protects the client_secret: it is only available when first generated, it can be stored as a one-way hash to prevent retrieval or leaks, and it can be changed and reset without changing the corresponding client_id. When an API Key is not marked as a client_secret, it will not be protected in the API Manager UI.

   - Located In: Select one of the following options, to specify how the credentials are sent:
     - header: The credentials are sent in the request header.
     - query: The credentials are sent as query parameters. This method is less secure because the client secret could be exposed in a log file.

     Note: If you migrated from API Connect V5, API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. For information about the differences, see Client ID behavior in API key security definitions.
   - Description: An optional description of the API key security scheme. You can use CommonMark syntax for rich text representation.
5. To reference another API key security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name: A key that enables this API key security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Reference from: Select a reference to another API key security scheme component.
6. If you are creating a new API key security scheme component, click Create.
   The security scheme component details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

- **Client ID behavior in API key security definitions**
  How the Client ID behaves in API key security definitions in IBM API Connect 10 compared to Version 5.

Client ID behavior in API key security definitions

How the Client ID behaves in API key security definitions in IBM® API Connect 10 compared to Version 5.

API key security definitions that contain multiple Client ID references, behave differently in Version 10 than in Version 5. Refer to the following table to understand the differences in Client ID behavior for different use cases.
Note: Although a client_id in the request body is supported, this data is not used during security requirement processing.

Table 1. Client ID behavior in V5 and V10

Use case	Description of security requirement	V5 behavior	V10 behavior
1	Allows client_id in the query, and the request contains multiple client_ids in the query.	Uses the first client ID in the request.	401 invalid client ID or secret.
2	Allows client_id in the header, and the request contains multiple client_ids in the header.	401 invalid client ID or secret.	401 invalid client ID or secret.
3	Allows client_id in the header, and the request contains multiple client_ids in the query and the header (1 in the query, 1 in the header).	401 client ID in wrong location.	Client ID in query is ignored.
4	Allows client_id in the query, and the request contains multiple client_ids in the query and the header.	Client ID in header is ignored.	Client ID in header is ignored.
5	Allows client_id in the query or header, and both the query and header contain multiple client_ids.	Header returns 401 client ID in wrong location. Query uses the first client ID in the request.	401 invalid client ID or secret.
6	Allows client_id in the header, and the request contains a valid client_id in the query, and an invalid client_id in the header.	401 client ID in wrong location.	401 invalid client ID or secret.
7	Allows client_id in the query, and the request contains a valid client_id in the header, and an invalid client_id in the query.	401 invalid client ID or secret.	401 invalid client ID or secret.
8	Allows client_id in the query or header, and both the query and header contain valid client_ids.	200 OK.	403 multiple client IDs.
9	Allows client_id in the query or header, and both the query and header contain invalid client_ids.	401 client ID in wrong location.	401 invalid client ID or secret.
10	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the query is valid.	200 OK.	Uses the valid one 200 OK.
11	Allows client_id in the query or header, and both the query and header contain a client_id, and the one in the header is valid.	401 client ID in wrong location.	Uses the valid one 200 OK.
12	Allows client_id in the query or header, and both the query and client_id is missing in the request (no security requirement, but client security is defined in the assembly).	401 invalid client ID or secret.	• When Return V5 Responses compatibility option is off: 401 client ID is missing. • When Return V5 Responses compatibility option is on: 401 invalid client ID or secret. For information about setting compatibility options, see Configuring v5 compatibility options.

Defining OAuth2 security scheme components

An OAuth2 security scheme component defines the settings for controlling access to the API operations through the OAuth authorization standard.

Before you begin

Before you can create an OAuth2 security scheme component, you must:

1. Create an OAuth provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Add the OAuth provider to a catalog. If you have not created any catalogs, use the Sandbox Catalog. See the OAuth instructions step in Creating and configuring Catalogs.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of an OAuth2 security scheme component, you must reference it from elsewhere in your API definition. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.

2. Expand Components then, if there are already one or more security scheme components defined, expand Security Schemes.
3. To create an OAuth2 security scheme component, click the add icon ⊕ alongside Security Schemes. To edit an existing OAuth2 security scheme component, click the component name in the navigation pane.
4. If you are creating a new OAuth2 security scheme component, you can either create it from scratch or you can reference another OAuth2 security scheme component.
   To create an OAuth2 security scheme component from scratch, provide the following information on the Definition tab:
   - Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Security Definition Type: Select oauth2.
   - Flow: Select one or more of the following options:
     - Implicit
     - Resource Owner - Password
     - Application
     - Access Code

     Note: The flow options that are available for selection depend on which options are supported by the selected OAuth provider.
     If you selected Resource owner - JWT as the supported grant type when you created the OAuth provider, you must select Resource owner - Password as the Flow for this security scheme.
   - OAuth Provider: The name of the OAuth provider to be used. This is the value of the `name` field that was auto-generated when the OAuth provider was created.
   - Description: An optional description of the OAuth2 security scheme. You can use CommonMark syntax for rich text representation.

   To reference another OAuth2 security scheme component, provide the following information on the Reference tab:
   - Security Scheme Name: A key that enables this OAuth2 security scheme component to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/securitySchemes/Security_Scheme_Name`

   - Reference from: Select a reference to another OAuth2 security scheme component.
5. If you are editing an existing OAuth2 security scheme component, provide the following information:
   - The URL endpoints (the applicable endpoints depend on the flow type):
     - Authorization URL
     - Refresh URL
     - Token URL

     Note: The URL endpoint values supplied here are maintained only for informative purposes, no validation or other action is applied to them by API Connect. The OAuth security that is applied depends on the specified OAuth provider.
   - Scopes:
     - To add a new scope, click Add. To edit an existing scope, click the options icon ⋮ alongside the required scope, then click Edit.
     - Provide the following information:
       - Scope: The scope identifier.
       - Description: An optional description of the scope. You can use CommonMark syntax for rich text representation.
6. If you are creating a new OAuth2 security scheme component, click Create.
   The security scheme component details are displayed for further editing.
7. Click Save when done.

What to do next

Apply the security scheme to an API or operation. For more information, see Enforcing security requirements on an API and Enforcing security requirements on an operation.

Defining OIDC security scheme components

An OIDC (OpenID Connect) security scheme defines settings for using your OIDC provider to control access to the API.

Before you begin

Before you can create an OIDC security scheme component, you must create a native OAuth provider and configure the OIDC settings for it.

1. Create an OIDC provider.
   - To use Cloud Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
   - To use API Manager, see Configuring a native OAuth provider or Configuring a third-party OAuth provider.
2. Configure the OIDC parameters for your native OAuth provider.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components > Security Schemes and then click ⊕ to add a new security scheme.
3. In the Add schema dialog box, provide the following settings before clicking Add:
   - Security Scheme Name (Key): provide a name for the new scheme.
   - Security Scheme Type: select openIdConnect
   - OpenID Connect URL: type the authorization endpoint URL for the OIDC provider.
4. On the OpenId Connect Security Scheme page, add information about the OIDC provider:
   - Type: select your OIDC provider from the list.

The list only displays the native OAuth providers that are configured for OIDC with a discovery URL provided in the OpenIDConnect Discovery path field, and are enabled for the catalog that the API is configured to use.

- OpenID Connect URL: When you select your provider, the URL is filled in for you with the discovery URL that was configured for the native OAuth provider.

5. Click Save.

Defining an HTTP bearer security scheme

An HTTP bearer security scheme is used to generate access tokens that are exchanged between the server and the client when calling the API operations.

About this task

For information on the use of bearer tokens with OpenAPI 3 APIs, see Bearer Authentication in the OpenAPI 3 specification.

If an HTTP bearer token is found in the request, its value is stored within the context as **`api->security->bearer_token`**. If an external URL validation is invoked, any response with a status code of 200 is stored within the context as **`api->security->bearer_validation_response`**.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components > Security Schemes.
3. Click Add.
4. In the Add Object dialog box, provide the following information:
   - Security Scheme Name (Key) - Provide a descriptive name for the new scheme.
   - Security Scheme Type - Select http.
   - Scheme - Select Bearer.
   - Bearer Format - Select JWT.
   - Validation Method - Select a method. If you select external-url, provide the following additional information:
     - Validation Endpoint - Provide the URL of the server used for validation. To ensure a secure connect, the URL should use the **`https`** protocol.
     - TLS Profile name - If the validation endpoint uses the **`https`** protocol, select the name of the TLS client profile to use for a secure connection.
   - Description - Provide a description of the JWT scheme.
5. Click Create to create the new scheme.
6. Click Save in the page header.

Defining link components

A link component is a reusable link definition that can be used to describe how various values returned by one operation can be used as input for other operations. In this way, links provide a known relationship and traversal mechanism between the operations.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To make use of a link component, you must reference it from elsewhere in your API definition.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Expand Components then, if there are already one or more link components defined, expand Links.
3. You can create a new link component, or edit any existing link component.
   - To create a link component, click the add icon ⊕ alongside Links, then refer to Creating a link.
   - To edit an existing link component, click the link component name in the navigation pane, then refer to Editing a link.

- **Creating a link**
  Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.
- **Editing a link**
  Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Creating a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Launch the link creation window. For details of the areas in your API definition from where you can create a link, see the following topics:

- Editing a response
- Defining link components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Create the link; you can either create a link from scratch, or you can reference a link that is defined in a link component.
   - To create the link from scratch, provide the following information on the Definition tab:
     - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/links/Name`

     - Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see Defining operations for a Path.
     - Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see Defining operations for a Path.
     - Description: A description of the link. You can use CommonMark syntax for rich text representation.
   - To reference a link that is defined in a link component, provide the following information on the Reference tab:
     - Name: If you are creating a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

       `#/components/links/Name`

     - Reference from: Select a reference to a link component.
2. Click Create.
   The link details are displayed for further editing; see Editing a link.

Editing a link

Links describe how various values returned by one operation can be used as input for other operations, providing a known relationship and traversal mechanism between the operations.

Before you begin

Open the details form for a link. For details of the areas in your API definition from where you can edit a link, see the following topics:

- Editing a response
- Defining link components

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.

- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Provide the following information:
   - Name: If you are editing a link component, this name defines a key that enables this link to be referenced from elsewhere in the API definition; the reference has the following format:

     `#/components/links/Name`

     To change the name, click Update, then click Save when done.
   - Operation ID: The ID of an existing operation; this field is mutually exclusive of the Operation Ref field. For details on defining operations, see Defining operations for a Path.
   - Operation Ref: A relative or absolute URI reference to an existing operation; this field is mutually exclusive of the Operation ID field. For details on defining operations, see Defining operations for a Path.
   - Parameters: A map representing parameters to pass to an operation as specified with Operation ID or identified via Operation Ref. The key is the parameter name to be used, whereas the value can be a constant or an expression to be evaluated and passed to the linked operation.
   - Request Body: The request body to use when calling the target operation.
   - Description: A description of the link. You can use CommonMark syntax for rich text representation.
   - Server: A server to be used by the target operation. Provide the following information:
     - Server URL The specified URL is used to determine the full URL endpoint for the calling the API, according to any vanity endpoint configuration in the Catalog in which the API is published. For full details, see Configuring vanity endpoints for a Catalog.
     - Server Description: An optional description of the host designated by the URL. You can use CommonMark syntax for rich text representation.
     - Server Variables A server variable defines a map between a variable name and its value. The value is used for substitution in the server's URL template.
       - To add a new server variable, click Add. To edit an existing server variable, click the variable name.
       - Provide the following information:
         - Server Variable Name (required).
         - Default value (required).
         - An optional rich text description. You can use CommonMark syntax for rich text representation.
         - One or more Enum Value entries (available when editing an existing server variable). Enum values specify an enumeration of string values to be used if the substitution options are from a limited set. To add an new Enum value, click Add, enter the value, then click Create. To edit an existing Enum value, click the Enum value.
       - If you are creating a new server variable, click Create. The server variable details are displayed for further editing.
2. Click Save when done.

What to do next

If required, use the breadcrumb trail to navigate to another location in the hierarchy of the object you are working on.

Specifying gateway and portal settings

Define general configuration settings for your API.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, then click Gateway and portal settings.
3. Provide the following information:
   - Phase: The phase of the lifecycle that your API is in; select one of the following options:
     - Realized (default) - The API is in the implementation phase.
     - Identified - The API is in the early conceptual phase and is neither fully designed nor implemented.
     - Specified - The API has been fully designed and passed an internal milestone but has not yet been implemented.
   - Testable: Select this option to allow the API's operations to be tested using the test tool in the Developer Portal.
     Note: For the test tool to work, an API must be included in a Plan in a Product that is staged in a Catalog.
   - CORS: Enable and configure cross-origin resource sharing (CORS) support for your API. For details, see Enabling CORS support for an API.
   - Target Services: Define web services that you want to use in your API definition. For details, see Defining target services for an API.

- Enforced: Select this option to enforce the API by using the DataPower API Gateway. Clear this option if you are managing the API on a gateway other than the DataPower API Gateway. Although not published to a gateway by API Connect, an unenforced API is still available in the Developer Portal for subscription by application developers.
- Properties: Add properties that can be referenced in your API definition. For details, see Setting API properties.
- Catalog Properties: Define property values that are specific to a particular Catalog. For details, see Defining Catalog specific property values.
- Activity Log: Configure your logging preferences for the API activity that is stored in analytics. For details, see Configuring activity logging.
- Exxtensions: Extensions added to the API to extend the OpenAPI specification. For details, see Adding an OpenAPI extension to an API.

Defining target services for an API

A target service defines a web service that you want to use in your API definition.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more target services defined, expand Target Services.
3. To define a new API target service, complete the following steps:
   a. Click the add icon ⊕ alongside Target Services in the navigation pane.
   b. Upload the service information from a stand-alone .wsdl file, or a .zip file that contains a WSDL file and its dependent documents, by either dragging and dropping your file, or browsing and selecting the file that you want to use.
   If you upload a .zip file, you can include in the .zip file an options file to specify additional directives. For details, see Using an options file when importing a WSDL service.
4. Select the service that you want to add.
5. Click Save to save your changes.
6. To view the source for an existing target service, click the target service name in the navigation pane.

Results

The target services that you add are now available in the palette on the Policies view for you to add to your API assembly flow; for more information, see Including elements in your API assembly.

Setting API properties

In addition to the pre-supplied API properties that you can use to control the behavior of API Connect policies, you can define your own API properties. The properties that you define can be referenced in your API definitions.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API properties include property name, value, and, optionally a specific Catalog to which a property value applies. For a list of pre-supplied API properties relating to various policies, see API properties.
Note: Once defined, an API property is read only.
For information on how to reference a property in an API definition, see Variable references in API Connect.

It is also possible to define properties that are specific to a Catalog and can be referenced by any of the APIs in that Catalog; for more information, see Creating and configuring Catalogs. Note that if you define a Catalog property of the same name as an API property, the API property takes precedence over the Catalog property.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more API properties defined, expand Properties.
3. Configure an API property.
   - To define a new API property, complete the following steps:
     - Click the add icon alongside Properties in the navigation pane.
     - Provide the following information:
       - Property Name: Enter a name for the property; this name is used to reference the property. The following character set is supported for the Name of an API property: `[A-Za-z0-9_-]+`. Spaces are allowed.
       - Value: A default value for the property. Leave blank if the property is to have a null vale by default.
       - Description: An optional description of the property. You can use CommonMark syntax for rich text representation.
       - Select Encoded if you want to hide the property values, or protect user passwords from casual observance.
         Note: If you encode a property value, it is saved in Base64 encoded form; it is **not** encrypted. If you subsequently clear the Encoded check box, the original property value is restored in its unencoded form.
     - Click Create.
   - To modify an existing API property, click the property name in the navigation pane. You can then change any of the configuration settings.
4. Click Save to save your changes.

What to do next

Optionally, define a value for the property that is specific to a particular Catalog; see Defining Catalog specific property values.

- **Defining Catalog specific property values**
  For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Defining Catalog specific property values

For any API property, you can define a value that is specific to a particular Catalog. For any API published to that Catalog, the API property assumes the Catalog specific value, overriding any default property value.

Before you begin

You must have previously created the API property that you now want to define a Catalog specific value for; see Setting API properties.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Tip: If you add or change an API property on an API that is already staged or published, you must re-stage or re-publish the Product that contains the updated API for the change to take effect.

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings then, if there are already one or more Catalog specific property values defined, expand Catalog Properties.
3. Configure a Catalog specific property value.
   - To define a new Catalog specific property value, complete the following steps:
     - Click the add icon alongside Catalog Properties in the navigation pane.
     - Type the Catalog Name exactly as it displays in the **name** field for the selected Catalog.
       Tip: For the best result, manually type the catalog's name instead of selecting its title. Using the catalog name is safer than using its title, because the title might not be unique within the provider organization and might be modified later (which breaks the association between the property and the catalog). The catalog's name is always unique within the provider organization and cannot be changed.
     - Click Create. The Catalog properties details for the specified catalog are displayed for further editing.
     - Alongside Property Overrides, click Add.
     - Provide the following information:
       - Property Name: Enter the name of the API property that you want to define a Catalog specific value for. The name **must** match the name of a previously defined API property; see Setting API properties.
       - Property Value: The Catalog specific property value. Leave blank if the property is to have a null value by default.
     - Click Create.
   - To modify an existing Catalog specific property value, click the Catalog name in the navigation pane. You can then change the Catalog name, and add, modify, or delete property override settings.
4. Click Save to save your changes.

Configuring application authentication for an API

Application authentication settings allow you to protect your API with a certificate, for example, by using TLS mutual authentication. You can select whether a client certificate is sent as a TLS client certificate or in an HTTP header.

About this task

Note: This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Enable application authentication, as follows:
   Note: To identify the application, you must enable a security requirement of type **`clientID`**.
   a. Select the Gateway tab, expand Gateway and portal settings, then click Application Authentication.
   b. Select Certificate.
3. Specify how the client certificate is sent to the gateway, as follows:
   a. In the navigation pane, click Application Authentication Source.
      Any existing application authentication source definitions are listed.
   b. Alongside Application Authentication Source, click Add.
   c. Select the required option, header or tls-cert.
      You can separately add one or both of the options.
      When the API is called, an X509 client certificate must be supplied, either in the specified HTTP header, or as a TLS client certificate from TLS mutual authentication. For any Developer Portal application that calls the API, the certificate must be entered in the Developer Portal user interface; for details, see Registering an application.

      The Gateway service to which the API is published can be configured to use TLS mutual authentication to secure API calls made to that Gateway service; for details, see Configuring the initial Gateway service. If you select this option, continue to sub-step d.

      If you are using a load balancer, you must configure the load balancer to use the specified HTTP header to relay the appropriate client certificate to the Gateway service after the load balancer terminates the TLS communication.

   d. If you select the tls-cert option, enable mTLS at the Gateway level.
      Enable mTLS by setting "Mutual authentication: Required" (or "Requested" if not all APIs use mTLS) in the TLS Server Profile that is specified for the API invocation endpoint in your gateway service configuration. The gateway service is configured in the Cloud Manager UI (requires cloud administrator permissions). For more information, see Registering a gateway service and TLS profiles overview.

      You can create a truststore (with the root or intermediate CA certificate) for use with the TLS Server Profile.

      The following example cURL command uses a client-cert during SSL:

      ```
      **curl -X GET 'https://GW-Server:9443/test/sandbox/mtls-testing/callmtls-call' -H 'X-IBM-Client-Id:
      1872xxxxxxxxxxxx' --cert my-leaf-cert.pem --key my-leaf-cert.key -k -v**
      ```

      Note: This feature is intended for the scenario where different applications are registered with different end certificates in the Developer Portal, which have the same intermediate or root CA issuer. The certificate passes Gateway-level mTLS if it matches the issuer available in the truststore, but allows access only to the API that matches the correct end certificate.
4. Click Create.
5. Click Save to save your changes.

Configuring activity logging

You can configure your logging preferences for the API activity that is stored in analytics, overriding the default activity logging behavior.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

An API event record exists for each API execution event in the Gateway server. By default, the content type for a successful API execution is activity, and payload for an API call the results in an error code. When you compose your API definition, you can change the type of content to log in these API event records. During API execution, the activity data is stored in the **`log`** context variable, which populates the API event record on completion of the API execution; for more information, see API activity logging context variables.

Note:

Activity logging that calls for logging of analytics data upon success doesn't apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but doesn't log successful cases.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon . To return to the design form, click the Form icon .

Procedure

1. Open the API for editing, as described in Editing an OpenAPI 3.0 API definition.
2. Select the Gateway tab, expand Gateway and portal settings, then click Activity Log.
3. Select Enabled, then select options for the Success Content and Error Content fields as follows:

Field label	Description
Success Content	Defines the type of content to be logged when the operation is successful. • none: API events are not logged. • activity: Logs the API resource URI. • header: Logs the API resource URI and HTTP headers. • payload: Logs API resource URI, HTTP headers, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is activity.
Error Content	Indicates what content to log when an error occurs. • none: API events are not logged. • activity: Logs the API resource URI. • header: Logs the API resource URI and HTTP headers. • payload: Logs API resource URI, HTTP headers, and payload; all information, including the payload that is received in a request or returned in a response, is recorded. The default value is payload.

4. Click Save to save your changes.

Including elements in your API assembly

An assembly is formed of elements that are applied to calls to and responses from operations in your API. Elements can be either policies or logic constructs.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

In the Policies view of IBM API Connect, you can add and configure elements in your assembly. You can also directly add elements to the OpenAPI definition of your API.

- **The assembly editor**
  The API Designer of IBM API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.
- **Adding elements to your assembly**
  Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.
- **Handling errors in the assembly**
  Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

The assembly editor

The API Designer of IBM® API Connect features a graphical editor that you can use to create assemblies. With assemblies, you can readily tailor your APIs to include elements such as activity logging and redaction of specific fields.

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM API Connect.

You can access the Assemble view by clicking the Gateway tab in the API editor, and then click Policies. This tab includes the following options:

- Palette - lists the available elements in the assembly flow.
- Canvas - used to arrange and visualize the elements in the assembly.
- Property sheet - used to configure the elements in the assembly.

The palette

The palette is a list of different elements that you can include in your assembly. To view the palette, click the plus icon on the canvas. You can use the Rotate icon to rotate the palette as you prefer. To maximize and minimize the palette view, click the Maximize and Minimize icons.

You can release the palette by clicking the Close icon ✕.

The canvas

You can use the canvas to create a graphical representation of the assembly flow. To add an element to the assembly flow from the palette, click the plus icon ⊕ at the appropriate location on the canvas and select the required element from the available list. To delete an element from the canvas, hover over the element and click the Delete icon 🗑.

Note: You must click Save in the Assemble view to save your assembly updates, and to make them appear in the Source view.
API calls are made at the initial, unfilled, circle, and returned at the final, filled, circle. You can insert elements between the two circles to modify the data received from the call, or returned by the response.

You can use the Show catches toggle to show and hide error catches in the palette. A catch is a section of the assembly that is applied when an API call results in the corresponding HTTP status code being returned. Click the catch section to open the property sheet for all your catches.

You can zoom the view of your canvas in and out by clicking the + and - icons. To fit the canvas to the screen size, click the Fit to screen icon ⛶.

The property sheet

When you select an element that is in the assembly by clicking it, details about the element are displayed in the property sheet. In this pane, you can configure the element's properties. The options available to you in the property sheet are specific to the type of element you are working with. For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down menu.

You can release the property sheet by clicking the Close icon ✕.

The behavior of an assembly

The assembly runs policies in order and acts on different contexts of the API call. When an API call is made, security and rate limits are enforced before the assembly is executed. During the assembly, the flow can be branched, thrown, and caught according to the policies available. The message context flows through the assembly, being used and altered by various policies. In addition to the message, other contexts can be accessed and created.

Security and rate limiting
: Before the assembly is executed, security and then rate limits are enforced.
First, security definitions and CORS access control are used to authenticate an API call. Any API Key security definitions are used to identify applications that have subscriptions to a Product containing the API. If a security definition does not allow access, the API call is rejected.

: If an application is identified by its client ID or client secret, a rate limit can be enforced based on the Plan or operation called.

The assembly execution sequence
: The assembly is executed in order from the initial, filled, circle to the final, unfilled, circle. However, there is room for branching, when **`if`** and **`operation-switch`** logic constructs are used, or for the remaining assembly to be ignored when a **`throw`** policy is executed.
The message is the context that is acted upon by any policy that isn't otherwise configured. At the beginning of the API call, the message is empty and, at the end of the API call, the message is used as the response.

: The request context contains the information that is sent by the API caller and varies with the type of operation called and the configuration of that operation. For example, a GET operation can never have a populated **`request.body`**, and you can configure an operation to have **`request.parameters`** (query parameters).
The first policy in an assembly acts on the request and produces the first instance of the message. If there are no policies, the request is returned to the caller.

Managing contexts
: Because the message can be overwritten, it is useful to create and reference new contexts where possible so that they are saved and reused during the API call.

  - Use the **`map`** policy to overwrite the message context when you need to execute a policy that only acts on the message.
  - Use the request context when you want to use the original request made to the API.
  - Use the **`map`**, **`invoke`**, and **`proxy`** policies to create new contexts when you want to save your message.
    Note: When you create a new context, unless you are also mapping to the message, the message is overwritten with an empty object.

: For example, **`invoke`** is the first policy in the assembly and its response overwrites the request as the message. The message is then acted upon by a **`validate`** policy, and a **`map`** policy then saves the message as a new context, ready for a second **`invoke`** policy to overwrite the message without losing the first **`invoke`** policy's output.

: You can also access contexts outside of the message or your custom contexts, but these contexts cannot be written to. For a list of contexts, see API Connect context variables.

Branches and catches
: Using logic constructs, such as **`operation-switch`** or **`if`**, you can execute different sections of the assembly when certain conditions are fulfilled. When the assembly branches, the subsection of the assembly contained by the construct is executed in the same manner as a complete assembly. However, contexts are shared with the complete assembly.
When a catch is triggered, either by an error occurring during the execution of a policy, or because a **`throw`** policy is encountered, the rest of the assembly flow is ignored. All contexts are shared by the catch being executed and when the end of the catch is reached, the API call is completed. There is no way to return from a catch to the rest of the assembly.

- Adding elements to your assembly

Related reference

- API Connect context variables

Adding elements to your assembly

Create your API assembly by using the Assemble view in the API Designer. You can access the Assemble view by clicking the Gateway tab in the API editor.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

You can use the assembly tool in the UI to create assemblies that are used to manipulate requests made to or responses made by any of your API's operations.

At any time, you can switch directly to the underlying OpenAPI YAML source by clicking the Source icon </>. To return to the design form, click the Form icon .

If you want to use the Source view to edit the source of your API definition, see execute OpenAPI extension for more information about how to configure the OpenAPI YAML.

For more information about the use of the assembly tool, see The assembly editor.

Procedure

To add elements to your assembly using the assembly tool, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Use the Policies view to add an element.
   Note: You must specify a version for the policy. To prevent errors due to incompatible versions of a policy between the API and the gateway, API Connect will only publish an API to the gateway if the policy version in the API exactly matches the version that is present on the gateway.
   a. Select the Gateway tab, then click Policies in the navigation pane.
   b. Click the plus icon ⊕ at the appropriate location on the canvas to view the palette that lists the available elements.
   c. Select the element that you want to add from the palette to the canvas by clicking it.
      Note:
      - Elements are applied in order from the initial, unfilled, circle to the final, filled, circle.
      - Unless an Operation Switch element is used, the whole assembly applies to every operation in the API.
   d. Add and edit properties of the element by clicking the element and using the property sheet.
      For some elements, you can add and remove properties by clicking Object Properties and selecting the property from the drop-down list. For information about the properties of policy elements, see API policies and logic constructs. For information about the properties of logic constructs, see Logic Constructs.
   e. Specify a version for the policy.
      To add a version, click the Source icon </>, and complete the `version` section of the policy YAML. For example:

      ```
      execute:
        - invoke:
            version: 2.2.0
            title: invoke
      ...
      ```

      You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions. For more information about how to configure the policy OpenAPI YAML, see execute OpenAPI extension.
4. Optional: Repeat Steps 3.b to 3.e for any additional elements that you want to add.
5. Click Save to save your changes.

Results

You have added one or more elements to your assembly.

Handling errors in the assembly

Use the catch section of the assembly to describe the handling of errors thrown during the assembly execution.

About this task

Note:

- This task relates to configuring an OpenAPI 3.0 API definition. For details on how to configure an OpenAPI 2.0 API definition, see Editing an OpenAPI 2.0 API definition.
- OpenAPI 3.0 APIs are supported only with the DataPower® API Gateway, not with the DataPower Gateway (v5 compatible).
- For details of current OpenAPI 3.0 support limitations, see OpenAPI 3.0 support in IBM® API Connect.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The catch section of the assembly is used to implement an assembly in the instance that an error is thrown during the assembly execution. For example, the assembly could contain a **`throw`** element, the API caller could fail to authenticate, or a policy could fail to execute correctly. Each error can be handled with a different catch and each catch can handle multiple status errors.

Procedure

To create a catch and include elements in it, complete the following steps:

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to apply a catch to.
3. Select the Gateway tab, then click Policies in the navigation pane.
4. Set the Show catches toggle in the menu bar of the canvas to the Show position.
5. Click Catches in the canvas, or a Catch icon  if one is displayed.
   The property sheet for the API's catches opens.
6. To add a default catch that is executed when an otherwise uncaught error is thrown, click Add default catch.
   Note: If you have a default catch before another catch in precedence, the default catch will activate even when the other catch's error is thrown.
7. To add a new catch, click Add catch.
8. To specify which errors the catch applies to, use the Select errors field to select the appropriate error.
9. Optional: To remove an error case from a catch, clear the corresponding checkbox from the Select errors drop-down. To clear all the error cases from a catch, click the cross corresponding to the total number of error cases in the Select errors field.
10. Optional: To change the precedence of your catches, use the Move up ↑ or Move down ↓ icons.
    If an error case is handled by multiple catches, the catch at the beginning of the list is applied.
11. To add an element to a catch from the palette, click the plus icon ⊕ at the appropriate location in the assembly flow. Select an element that you want to apply to the catch by clicking it.
12. Click Save to save your changes.

What to do next

If you added a catch for ConnectionError, SOAPError, or OperationError, you must add the same error to the Stop on error setting for the **`Invoke`** policy in your assembly. Otherwise, if the error occurs during the execution of the **`Invoke`** policy, it is not caught, the policy execution is allowed to complete, and the assembly flow continues. For details on configuring an **`Invoke`** policy, see Invoke.

For details of all the errors that can be returned by the assembly and are available to the catch function, see Error cases supported by assembly catches.

Validating the OpenAPI YAML source

How to validate the OpenAPI YAML source against swagger specifications when you're editing an API.

About this task

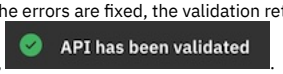
When you're configuring an API in the API editor, you can validate the OpenAPI YAML source by clicking Validate > With specifications. If any swagger parser validation errors are found, an error icon is displayed that you can then click to see the individual errors, and where they occur in the YAML. You can then fix the errors, save the updates, and continue to validate the OpenAPI YAML throughout the API configuration process.
Note:

- OpenAPI validation does not show gateway or policy errors that will stop your API from being staged or published. This type of validation occurs only when you try to stage or publish your API. For more information, see Staging an API or Publishing an API.
- You can also validate your API document by using governance rulesets. For more information, see Validating an API or product document by using the governance service.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Procedure

To validate the OpenAPI YAML source, complete the following steps.



1. Open the required API for editing, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.
2. Click Validate > With specifications from the menu bar in the header.

3. If any swagger parser validation errors are found, an error icon is displayed on the header menu bar, with the number of OpenAPI errors found displayed next to the icon.

   For example,  .

4. You can then click the error icon to see a detailed list of the errors, and their location in the YAML. If you're in Form view, you can click an individual error to navigate directly to the relevant API section in the form.
5. After you fix the error, click Save to save your updates, and then click Validate again.
6. When all of the errors are fixed, the validation returns a success message.

   For example, 

.

Validating an API or product document by using the governance service

How to use governance rulesets to validate and enforce organizational governance policies and best practices. You can run validation scans on API and product documents from the API Manager UI, the API Designer UI, or the toolkit CLI.

Before you begin

Before you can run validation scans you must have governance enabled on your management subsystem by your system administrator. See Enabling governance on Kubernetes, and Enabling governance on VMware for more information. If governance is enabled in your deployment, the Governance icon is displayed in the side menu bar. If you are only a catalog or space member of a provider organization, a Governance tab is visible in the catalog menu.

The governance service is available to all user roles.

Tip: Before using the governance service to validate any API documents, you should first run Validate > With specifications to validate the OpenAPI YAML source. For more information, see Validating the OpenAPI YAML source.

About this task

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API and product development process. The service contains the following types of rulesets:

API
: Rulesets to validate your API documents.

  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating APIs.
  - Global rulesets - these are pre-configured IBM and Spectral rulesets that contain the rules that are shared with your provider organization for validating APIs, and cannot be edited. Note that the Spectral ruleset names are prefixed by spectral-, and that their version matches the version of that ruleset that's available in Spectral.

Product
: Rulesets to validate your product documents. Note that the validation scan of products looks only at the product yaml; it does not include the scanning of any API documents that the product refers to.

  - Provider organization rulesets - these are custom rulesets that contain the rules that are created in, and are specific to, your provider organization for validating products.
  - Global rulesets - these are pre-configured custom rulesets that contain the rules that are shared with your provider organization for validating products, and cannot be edited.

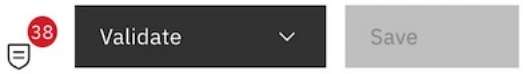
You can create your own provider organization rulesets to validate your Swagger, OpenAPI, AsyncAPI, and product documents against, or use the global rulesets that are provided for your organization. For more information about configuring rulesets, see Configuring governance in the API Manager.

Governance in API Connect is based on the open source Spectral linter; for more information about Spectral, see https://docs.stoplight.io/docs/spectral/674b27b261c3c-overview.

You can complete the instructions that are in this task by using the API Manager UI, or by using API Designer when the UI is online, and is connected to a cloud instance that has the governance microservice enabled on it. You can also use the toolkit CLI; for details see Validating an API or product document by using the toolkit CLI.

The following validation scan methods are available:

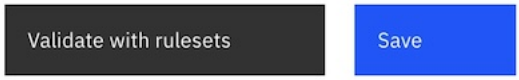
- Validate an API document from within an API
- Validate a product document from within a product
- Validate one or more API or product documents from within the Governance section
- Validate one or more published API or product documents from within a catalog or space



Procedure

- To validate an API document from within the API, complete the following steps.
  1. Open the required API for validating, as described in Editing an OpenAPI 2.0 API definition or Editing an OpenAPI 3.0 API definition.

2. Click Validate > With rulesets from the menu bar in the header.



3. Select the rulesets that you want to validate your API document against, and click Next.
   If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
5. Click Validate.
   If any validation errors are found, a scorecard is displayed showing the results of the validation. The API can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
6. Optional: You can click Download to download the results of the validation into a .csv file.
7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
8. Click Done when finished.
   The API Design page is displayed.
   If validation errors were found during the scan, the ruleset status icon in the header menu bar displays the number of errors found, for example:

   You can click on the ruleset status icon to see a detailed list of the errors, and their location in the YAML. You can also then click on an individual error to navigate directly to the relevant section in the API.

- To validate a product document from within the product, complete the following steps.
  1. Open the required product for validating, by clicking on the title of the product in the Products tab of the Develop page.
  2. Click Validate with rulesets from the menu bar in the header.

  3. Select the rulesets that you want to validate your product document against, and click Next.
  4. Select the rules from within the rulesets that you want to use for the validation. By default, all of the rules are selected.
  5. Click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. The product can then be updated to resolve the validation errors, and validated again. If no errors are found, a success message is displayed.
  6. Optional: You can click Download to download the results of the validation into a .csv file.
  7. Optional: You can click Back to change the rulesets and rules, and then run the validation again.
  8. Click Done when finished.
     The product Design page is displayed.
- To validate one or more draft API or product documents from within the Governance section, complete the following steps.
  1. In the side menu bar, click  Governance.
     The Governance page is displayed.
  2. Click the Rulesets tab.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.
  7. Select the APIs or products that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
  8. Optional: You can click Download to download the results of the validation into a .csv file.
  9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  10. Click Done when finished.
- To validate one or more published API or product documents from within a catalog or space, complete the following steps.
  1. Select the catalog or space that you want to run the validation in, and then select Governance from the menu bar.
  2. Select Rulesets.
  3. If you want to validate one ore more API documents, click the API tab. If you want to validate one or more product documents, click the Product tab.
  4. Click Validate.
  5. Select the rulesets that you want to validate against, and click Next.
     If there are matching tags in the APIs and in the rulesets, the validation process preselects which rulesets to use for the scan. However, you can override this preselection with rulesets of your choice. For information about how to add tags, see Configuring governance in the API Manager, and Adding tags to an API.
  6. Select the rules from within the rulesets that you want to use for the validation, and click Next.
  7. Select the APIs or products that you want to validate, and click Validate.
     If any validation errors are found, a scorecard is displayed showing the results of the validation. If no errors are found, a success message is displayed.
  8. Optional: You can click Download to download the results of the validation into a .csv file.
  9. Optional: You can click Back to change the rulesets, rules, and APIs, and then run the validation again.
  10. Click Done when finished.

Results

Your API or product document is validated against one or more rulesets.

What to do next

You can use the results of the validation to help you improve your API or product document. You can also use the results to help you edit the rulesets, and create new rulesets; see Configuring governance in the API Manager for more information.

You can also run validation scans on a catalog or space, to check one or more of the API documents that it contains. For more information, see Scanning your catalogs and spaces.

  How to use the API Connect toolkit CLI to run governance validation scans on your API or product documents.

Related information

- The governance ruleset lifecycle

Validating an API or product document by using the toolkit CLI

How to use the API Connect toolkit CLI to run governance validation scans on your API or product documents.

About

The governance service in IBM® API Connect can be used to validate and enforce organizational governance policies and best practices to your API development process. The following information provides details of the toolkit CLI commands for running and managing validation scans on your API or product documents. You can also validate an API or product document by using the API Manager and the API Designer UIs. For more information about validation scanning, see Validating an API or product document by using the governance service.

The following validation scan methods are available by using the toolkit CLI:

- Validate a single API or product document that is stored locally
- Validate one or more API or product documents that are stored on the management server

Validate a single API or product document that is stored locally

To run a validation scan on a single API or product document against one or more rulesets, complete the following steps. The document must be stored locally.

1. Log in to the toolkit as the owner or an admin of your provider organization.
   For example:

   ```
   apic login --server platform_api_host_name --username user_id --password password --realm provider/identity_provider
   ```

   You can determine which identity provider to use in the `--realm` parameter by entering the following command to see a list of all available identity providers (you do not need to be logged in to use this command):

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   ```

   For example,

   ```
   apic identity-providers:list --scope provider --server platform_api_host_name --fields title,realm
   total_results: 2
   results:
     - title: API Manager User Registry
       realm: provider/default-idp-2
     - title: Corporate LDAP user registry
       realm: provider/corporate-ldap
   ```

   The `title` value should enable you to determine which identity provider to use; you can then copy the corresponding `--realm` parameter directly from the displayed `realm` value. For any identity providers that were created by your administrator after API Connect was installed, the names will have been determined at creation time. The default API Manager Local User Registry for login as a member of a provider organization is `default-idp-2`.
   For full details of the `apic login` command, see Logging in to a management server.

2. Run the **compliance:validate** toolkit command in `governance` mode.

   ```
   apic --mode governance compliance:validate --org <target_org> --server <platform_api_host_name> --rulesets
   <ruleset_name_1>,<ruleset_name_2> API_OR_PRODUCT_FILE
   ```

   where:
   - `<target_org>` is the name of the provider organization that owns the APIs to be validated.
   - `<platform_api_host_name>` is the hostname portion URL of server that hosts the API Manager (the "management server").
     Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after `https://` and ending before `/manager`).
   - `<ruleset_name_1>,<ruleset_name_2>` is a comma-delimited list specifying the names of the rulesets to be applied to the API or product. (Specify each ruleset name; do not use the ruleset IDs.)
   - `API_OR_PRODUCT_FILE` is the path and filename of the document to be validated.

Validate one or more APIs or products that are stored on the management server

This operation runs a validation scan on all of the draft APIs, or all of the products, that are listed in the `COMPLIANCE_REQUEST_FILE`. You can scan only APIs, or only products, at any one time. The APIs must be stored as draft APIs in your provider organization.

1. Create a JSON `COMPLIANCE_REQUEST_FILE` that specifies the rulesets to use during validation, and the location of either the draft APIs or the products that you want to scan. The file can contain URLs only for APIs, or only for products; you cannot list both API and product URLs in the same file.
   The following example shows a configuration file that specifies two draft APIs, and two rulesets. In the `spectral-oas` ruleset, the `info-contact` rule is disabled and will be ignored during validation.

```
{
  "apiUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/a08898fe-b422-41d3-b058-c3280d632e93","https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-apis/26692eab-f43b-4af3-985c-2deaa401eb7f"],
  "config" : {
    "rulesets": [
      {
        "rulesetName": "spectral-oas",
        "disabled": ["info-contact"]
      },
      {
        "rulesetName": "spectral-owasp",
        "disabled": []
      }
      ]
 }
}
```

The following example shows a configuration file that specifies one product document.

```
{
  "productUrls" : ["https://example.com/api/orgs/768a5f80-177c-4100-b2b6-57ce6c4bf761/drafts/draft-product/a07968fe-b422-41d3-b058-c3280d632e93"],
  "config" : {
    "rulesets": [
      {
        "rulesetName": "product-info",
        "disabled": ["subscribe"]
      },
      {
        "rulesetName": "product-rate",
        "disabled": []
      }
      ]
 }
}
```

Where:

- **`apiUrls`** is a comma-delimited list of API URLs. Each URL specifies the location of the draft APIs in a particular provider organization.
- **`productUrls`** is a comma-delimited list of product URLs. Each URL specifies the location of the product document in a particular provider organization.
- **`rulesetName`** is a list of rulesets to be applied to the APIs or products during validation.
  For each ruleset in the list, you can optionally add the **`disabled`** property with a comma-delimited list of rules to ignore during validation.

2. Log in to the toolkit as the owner or an admin of your provider organization. See Step 1 for details.
3. Run the **compliance:validate_all** toolkit command in **`governance`** mode.

```
apic --mode governance compliance:validate_all --org <target_org> --server <platform_api_host_name>
COMPLIANCE_REQUEST_FILE
```

where:

- ***`<target_org>`*** is the name of the provider organization that owns catalog containing the APIs to be validated.
- ***`<platform_api_host_name>`*** is the hostname portion URL of server that hosts the API Manager (the "management server").
  Tip: To determine the hostname, you can open the API Manager in a browser and copy the hostname from the URL in the address bar (beginning after **`https://`** and ending before **`/manager`**).
- ***`COMPLIANCE_REQUEST_FILE`*** is the path and filename of the configuration file that lists the API or product documents, and the rulesets to be used during the validation (for example, validate-apis.json).

LDAP authentication

The Lightweight Directory Access Protocol (LDAP) is an internet protocol for accessing and maintaining distributed directory information services over a network. If you rely on LDAP to authenticate users for web applications, take a minute to review the contents of this topic before beginning.

Programming guidelines

When authenticating with LDAP, observe the following guidelines:

- Use only a LDAP interface -- Users can only be authenticated via a connection to an LDAP server.
- Active Directory -- Use of an Active Directory interface is prohibited, however, LDAP authentication with Active Directory is supported.
- Administrator properties -- The LDAP administrator must have access to all user's LDAP properties.

LDAP attributes read by IBM® API Connect are as follows:

Attribute	Definition
`mail`	User's SMTP email address.
`cn`	Used internally to determine user's common name.
`sn`	Used internally to determine user's last name or surname.
`givenname`	Used internally to determine user's first name.
Prefix from **`Search dn`**	Used as username.

Using an LDAP Server for User Authentication

Every entry in an LDAP directory server has a distinguished name (DN). The DN is the name that uniquely identifies an entry in the directory. A DN is made up of **`attribute=value`** pairs, separated by commas. For example:

```
cn=Ben Gray,ou=editing,o=New York Times,c=US
cn=Lucille White,ou=editing,o=New York Times,c=US
cn=Tom Brown,ou=reporting,o=New York Times,c=US
```

Any of the attributes defined in the directory schema can be used to make up a DN. The order of the component attribute value pairs is important. The DN contains one component for each level of the directory hierarchy from the root down to the level where the entry resides. LDAP DNs begin with the most specific attribute (usually some sort of name) and continue with progressively broader attributes, often ending with a country attribute. The first component of the DN is referred to as the Relative Distinguished Name (RDN). It identifies an entry distinctly from any other entries that have the same parent. In the previous examples, the RDN "cn=Ben Gray" separates the first entry from the second entry, (with RDN "cn=Lucille White"). These two example DNs are otherwise equivalent. The attribute=value pair making up the RDN for an entry must also be present in the entry. (This is not true of the other components of the DN.)

Examples

In the following examples, a user search is performed from Base DN. The search is done anonymously, or if authenticated bind is used, an authenticated user is used. Search DN appends the prefix, the given user name, and the suffix. If the prefix used is (`uid=` and the suffix used is "`)`", `uid` becomes the user name attribute. The default search filter used is: `(|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}))` and attributes used for prefix are also added to the search filter. In this case, where '(`uid=`' is the prefix, when searching for users, the search filter becomes:

```
  (|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}*)(uid={filter}*))
```

where `{filter}` is replaced by actual text.
The authenticated bind DN is a user on the external LDAP server permitted to get base DNs and search the LDAP directory within the defined search base. It should also be able to read other user properties and be used if anonymous access to LDAP to get base DNs and to search and get access to user attributes is not allowed. When a search is performed for *Steve*, the LDAP query filter shown in the following example is used and search is done from base DN specified in UI. When the user's DN is returned, the DN and password are used to authenticate the user:

```
(|(cn=Steve*)(sn=Steve*)(mail=Steve*)(givenName=Steve*)(uid=Steve*)).
```

For bind during login calls, the search string used is the prefix. For example, if the prefix is '(`uid=`', the search string used to search for a user during log in becomes: (`uid=Steve`).

Using the mail attribute as the user name

When you want to use an email address as the user name, (for example *steve@company.com*), you typically use the mail attribute as the prefix '(`mail=`'. In this case, use the following search string to perform the search internally (assuming '(`mail=`' as prefix):

```
(|(cn=steve@company.com*)(sn=steve@company.com*)(mail=steve@company.com*)
(givenName=steve@company.com*)(mail=steve@company.com*))
```

In the previous example, if DN is found, the password is used with the DN to perform a bind. The first result is taken, so be sure to use a unique attribute for username. Next, the LDAP properties for the user are read (`cn`, `sn`, `mail`, `givenName`). If LDAP properties cannot be read using the logged-in user, they are read from the user's DN using authenticated bind credentials. If the user name attribute differs, it is also queried for. For example, if the prefix is '(`uid=`', the `uid` attribute is also read from the user's DN object:

```
(|(cn={filter}*)(sn={filter}*)(mail={filter}*)(givenName={filter}*))
```

Note: The prefix and suffix cannot be used to get a user's DN directly. For example, the following attempt to directly get a user's DN fails:

```
Prefix: "uid="_home_markdown_jenkins_workspace_Transform_in_SSMNED_10.0.8_com.ibm.apic.toolkit.doc_con_ldap_requirements_,
Suffix: ",ou=users,dc=company,dc=com"
```

LDAP referrals

LDAP referrals allow a directory tree to be partitioned and distributed between multiple LDAP servers. An LDAP referral is a domain controller's way of indicating to a client application that it does not have a copy of a requested object, while giving the client a location that is more likely to hold the object. The client then uses the object as the basis for a DNS search for a domain controller.

API Connect support for LDAP referral includes:

- Searching for users that are part of multiple Active Directory trees and forests.
- Authenticating users in the Cloud Manager, API Manager and the Developer Portal.

Note: API Connect LDAP referral support is dependent on the following conditions:

- A single LDAP host/port is configured with administrator credentials and all users are referred to from the tree/server's base DN.
- As part of the user search following the LDAP referral , the same administrator credentials are used in the downstream trees/forests.
- LDAP API authentication does not support external LDAP referral. Internal LDAP referral is supported.

Authentication URL user registry

You can use an Authentication URL user registry to specify a REST authentication service to manage user authentication, and to optionally provide additional metadata to be embedded in the token.

This support can optionally enable any of the following:

- Providing the authenticated credential to IBM® API Connect. For example, the user logs-in with user name: `spoon`, and password: `fork`. When the user is authenticated, the credential becomes `cn=spoon,o=eatery`. The credential is kept in the OAuth **access_token** to represent the user.
- Providing metadata support. Allow extra metadata to be stored in the `access_token`.
- Overriding the `scope` that the application receives after a successful OAuth protocol processing. By responding with a specific header, the Authentication URL endpoint can replace the `scope` value that the application receives. For example, you can provide a specific resource owner an account number within the `scope` header response for use in future processing steps.

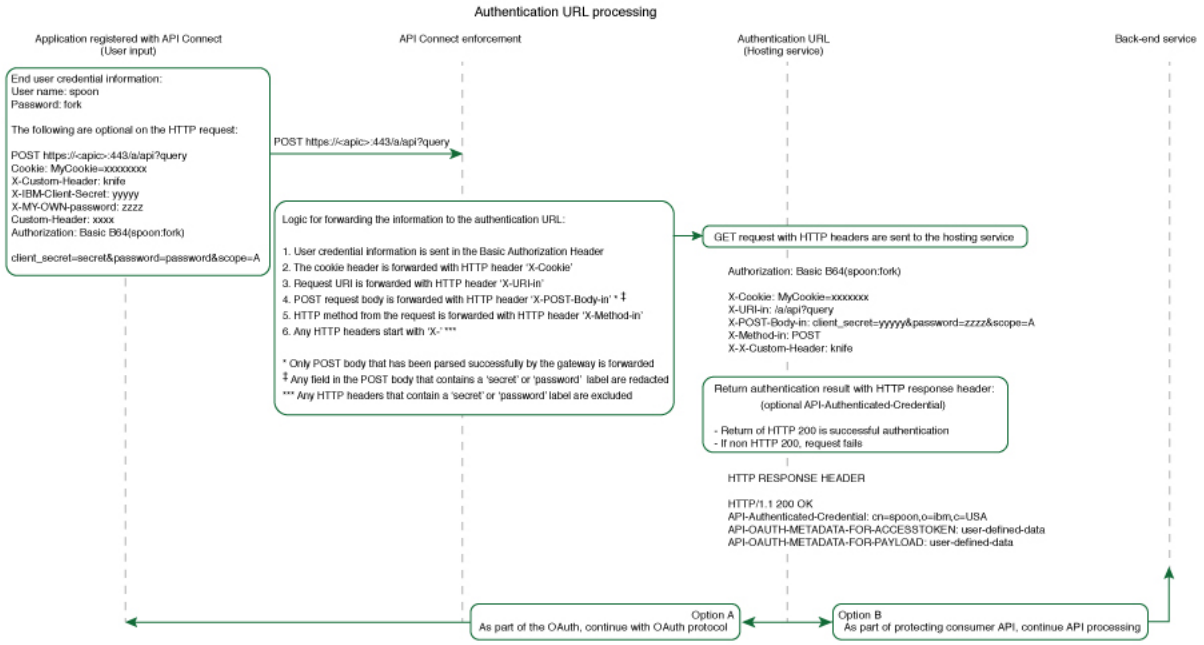
When you call the Authentication URL user registry, the API Connect gateway sends a GET request with HTTP headers and then processes any HTTP response from the URL. For authentication, a REST authentication service is expected at the Authentication URL.

The following response from the REST authentication service indicates that user authentication is successful and that API Connect will use `cn=spoon,o=eatery` as the user identity.

```
HTTP/1.1 200 OK
Server: example.org
X-API-Authenticated-Credential: cn=spoon,o=eatery
```

For information on how to configure a User Security policy in an API assembly for use with an Authentication URL user registry, see User Security policy.

For an example of an OAuth provider configuration that uses an Authentication URL user registry, see Example - using multiple OAuth policies in an OAuth provider assembly.



API Connect considers any non-200 HTTP response code a failed user authentication attempt.

When an Authentication URL user registry is invoked, two HTTP response headers are available that include metadata in the access token or the response payload that contains the access token. For more information, see OAuth external URL and authentication URL. The two metadata response headers are:

```
API-OAUTH-METADATA-FOR-ACCESSTOKEN
API-OAUTH-METADATA-FOR-PAYLOAD
```

When an Authentication URL is invoked, an HTTP response header is available to override the requested `scope` from the application. For more information, see Scope. The response header is:

```
x-selected-scope
```

If you are using the DataPower® API Gateway rather than the DataPower Gateway (v5 compatible), this diagram is provided for guidance only and is not fully accurate for this release.

Activating an API

After you have created an API definition you can activate it to auto-publish your API document and make it available for testing.

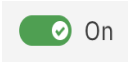
About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When you activate an API, API Connect automatically completes the following actions:

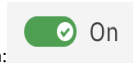
- Creates a draft Product, adds the API to the Product, and publishes the Product to the Sandbox Catalog so that the API is available to be called. The Product has the title *api_title* auto product. Note that if you later want to delete the draft Product, you cannot delete it directly; instead, delete the API and the draft Product is deleted together with the API; see Deleting an API definition. If you want to remove the Product from any Catalogs to which it is published, you must do this separately; see Removing a Product from a Catalog
- Subscribes the Sandbox test application to the Product so that you can immediately test the API in the test environment. For information on testing an API, see Testing an API.

To activate an API, you must be assigned a role that has the `Product:Manage` and `Subscription:Manage` permissions. The pre-supplied Developer role has these permissions by default; if you are assigned a custom role it must have these permissions. For more information, see Creating custom roles.



Note:

- The API activation will not complete successfully if lifecycle approval is enabled in the Sandbox Catalog for the Stage, Publish, or Replace actions. If any such lifecycle approvals are enabled, then to be able to activate an API they must be disabled; for information on lifecycle approval settings, see Creating and configuring Catalogs.
- To activate an API from the API Designer user interface, you must be connected to a Management server; API activation is not available with API Designer in offline mode. For more information, see Logging in from API Designer.
- Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "`(?`" cannot be validated or published. An error message is returned. For example:



```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0,
col: 0)
400
```

Procedure

To activate an API and auto-publish your API document, complete the following steps:

1. In the navigation pane, click  Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Under Testtab, click Target Configuration. The Preferences page opens.
4. Set the Auto-publish toggle to the On position: 

Results

On successful completion, the API is shown as On: 

You can stop the API by moving the activation slider control to the Off position: 

If you stop an API, the application subscription is deleted, and the auto Product is removed from the Sandbox Catalog.
Note: You can select a Catalog of your choice, or you can opt to use the Sandbox Catalog by selecting **Use the default built-in Sandbox Catalog**. For more information, see Specifying the testing preferences for an API.
If you make a change to the API, it is republished automatically, You can also republish a running API manually by stopping it and then re-activating it.

The error indicator shows whether there are validation errors in the OpenAPI source for the API definition. If there are errors, click the icon for more details:

You can also activate an API during the creation process, and on the API test page; see Creating an API definition and Testing an API.

Note: If an OpenAPI 3 API contains a response wildcard (which is not supported), publishing is disabled for that API. You must correct the problem before you can publish the API.

Testing an API

Select a test tool and verify that your API works as you intended.

Before you publish an API where customers can access it, you need to test it and ensure that it is defined and implemented correctly. API Connect offers tools for running both simple and complex tests, in different environments. Use the following list of options to choose the test tool that best meets your needs:

- Execute and debug the API in the Test tab
  On the Test tab, you can quickly invoke your API from the API Connect UI with minimal preparation. The Test tab offers full control over the API call through a simple set of fields where you can define your request. The response includes both a visual flow diagram and a code trace that shows how the API's process flow is executed. Note: the Test tab tool is only available to APIs that use the DataPower API Gateway.

- Call the API externally from the Automated API behavior testing application as explained in Testing an API with Automated API behavior testing
  Automated API behavior testing provides a simple set of fields where you can quickly invoke your API. You can automate tests and define schedules for running them. You can even set up API monitoring and receive alerts on your API health before issues occur.

- Call the API from a local test environment
  The Local Test Environment is a lightweight API Manager, running on your computer, that allows you to rapidly test APIs without connecting to an API Connect management server.

- Run a simple test in the Policies editor
  Note: The Test panel is deprecated and might be removed without warning.
- Use the Try it tool in the Explorer tab to run simple tests
  You can use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can check the descriptions of the different artifacts, and review any schemas or examples, and you can also use the Try it tool to test the behavior of the API.

Note: Due to CORS, when a test call is made with a browser-based API test tool, an HTTP OPTIONS call is made to the API first. The OPTIONS call:

- Does not use any credentials, so is not attributed to any consumer organization.
- Is logged as an API event in the analytics data. Because the OPTIONS call does not use credentials, the API events are only visible in analytics data in the Cloud Manager and API Manager UIs. The OPTIONS events are not visible in the developer portal analytics view, which includes only analytics data for a single consumer organization.
- Is not included in consumer rate limits.
- Is included in consumption-based licensing (if used).

- **Locating API information on the Endpoints tab**
  The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).
- **Using the Test tab to debug your API**
  Use the Test tab to execute calls and trace the API's actions in API Connect.
- **Testing an API with Automated API behavior testing**
  Use the IBM Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it executes properly.
- **Testing an API with the Policies editor**
  IBM API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.
- **Testing an API with the Local Test Environment**
  Use the Local Test Environment (LTE) to test APIs on your local machine, without the need to connect to an API Connect management server. The Local Test Environment is a lightweight API Manager running on your local machine. It allows you to rapidly test APIs locally.
- **Testing an API with the Explorer tab**
  Use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can also use the Try it tool to test the behavior of the API.

Locating API information on the Endpoints tab

The assembly tool's Endpoints tab opens a page that displays information for use when you call APIs externally. This tab displays only when an API's status is Online (the API was activated).

Use the Endpoints tab to retrieve information that you can use when you call the API from an application.

Note: The fields in the Sandbox Sample Application Credentials section apply to the assembly tool's built-in client application and not to any application that you created. The credentials that display here are the default credentials that display in the assembly tool Test panel's "Identification" section.

To copy information from the Endpoints tab, click  next to a field.

The following values for the API are displayed in the Endpoints tab so that you can copy them and paste them into calls:

Base API Endpoint
: The URL representing the endpoint of the API that you are editing and testing. To invoke the API, append one of its supported queries (path and parameters) to this URL.

Client ID and Client Secret
: The values of the built-in test application's client ID and client secret. You can invoke APIs externally by providing the application's credentials in the request header.

OAuth Token URL
: If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can obtain an access token for calling the API.

OAuth Auth URL
: If you specified an OAuth provider in the API's security definition, then this field displays the URL where you can submit an access token and receive an authorization token in exchange. You then use the authorization token when calling the API.

Rate Limit
: If you specified a rate limit on the Security panel when you created the API, the limit is displayed here for reference. If you did not specify a rate limit, the default rate limit displays.

Using the Test tab to debug your API

Use the Test tab to execute calls and trace the API's actions in API Connect.

The Test tab not only lets you quickly invoke an API with any needed headers and parameters, but lets you view the content of the response in both parsed and raw format. Additionally, you can view a trace of the actions execute as the API's process flow operates to complete the call. Viewing the trace can help you debug problems with the API's execution.

Note: The Test tab tool is only available to APIs that use the DataPower API Gateway.
You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Complete the following tasks to prepare your API for testing, execute requests, and debug responses.

1. Preparing an API for debugging with the Test tab
   Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.
2. Specifying the testing preferences for an API
   By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.
3. Sending the API request
   Fill in fields to set up the request for an API that you want to debug on the Test tab.
4. Reviewing the API response and trace
   Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.

5. Testing a GraphQL API with the Test tab
   For a GraphQL API definition, the Test tab contains a GraphiQL editor. You can use the GraphiQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphiQL editor.

Preparing an API for debugging with the Test tab

Ensure that your API's definition meets the requirements for debugging it in the API Connect Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

To invoke your API in the Test tab, the following requirements must be satisfied:

The DataPower API Gateway is configured to support the API probe
: To enable the Test tab's trace feature, the DataPower API Gateway must be configured to support gateway peering and the gateway probe. In a gateway service running in Kubernetes, the API probe is automatically enabled. In a gateway service running external to Kubernetes, the DataPower configuration must be added to the application domain supporting API Connect. Check with your administrator to confirm that gateway peering and the gateway probe are enabled as explained in Configuring DataPower API Gateway.

The API uses the DataPower API Gateway
: A gateway exposes APIs to calling applications, and provides processing actions that enable the APIs to integrate with various endpoints. API Connect supports two versions of the DataPower Gateway, but you can only debug APIs that use the DataPower API Gateway. The v5-compatible gateway is not supported. If your API definition has CORS enabled but you cannot see the Test tab, the API is probably configured to use the wrong version of the gateway.
  You can determine which gateway your API uses by completing the following steps:

  1. Log in to API Manager.
  2. In the navigation list, click  Develop, then select the APIs tab.
  3. Click the title of the API you want to test.
  4. On the API's Design page, locate the Gateway field and note which option is selected.

  You can change the gateway selection for an API on the Design page, but you must ensure that the policies used in the API's process flow are compatible with the new selection. For information on changing the gateway for an API, see Specifying the gateway type for an API definition.

CORS is enabled in the API definition
: Cross-Origin Resource Sharing support ensures that the API can be accessed from another domain. CORS support must be enabled for your API to be properly invoked and traced. If your API uses the API Gateway but you cannot open the Test tab, it's possible that CORS was not enabled in the API definition.
  You can enable CORS for you API by completing the following steps:

  1. Log in to API Manager.
  2. In the navigation list, click  Develop.
  3. On the Develop page, click the name of the API you want to test. The API's Design page appears.
  4. Under the Gateway tab, locate the CORS field and select it to enable support.
  5. Click Save in the page header.

The API is published in the Sandbox catalog with the default Product/Plan, or a specified catalog and Product/Plan
: By default, when you test an API with the Test tab, a default Product/Plan is generated for the API and published to the built-in Sandbox Catalog. However, you can optionally specify a range of API testing preferences including an alternative Product/Plan, and target Catalog; for more information, see Specifying the testing preferences for an API. When you publish (activate) an API, the API is enabled online and becomes available for use. You cannot execute an offline API, even for testing purposes. You can set an API online by completing the following steps:

  1. Log in to API Manager.
  2. In the navigation list, click  Develop.
  3. On the Develop page, click the name of the API you want to test.
  4. In the Design page header, click the settings icon . The **Preferences** page appears.
  5. Set the Auto-publish toggle to On position.

Next topic: Specifying the testing preferences for an API

Specifying the testing preferences for an API

By default, when you test an API with the Test tab, a range of test parameters are preconfigured. For example, a default Product is automatically generated, to which the API is added, and that Product is published to the Sandbox Catalog. However, you can configure testing preferences for each of your APIs, including the required Product and target Catalog.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: This feature is not available if you are using the Local Test Environment.

Procedure

1. Open the required API for editing, in either of the following ways:
   - During the initial creation of an API, the API wizard guides you to enter the minimum configuration settings; on completion of the initial configuration, click Edit API.
   - To open an existing API for editing, complete the following steps:

- In the navigation pane, click Develop, then select the APIs tab.
- Click the title of the API version that you want to work with.

2. Under the Test tab, click Target Configuration.
   The Preferences page opens.
3. Use the Edit links to configure the following testing preferences, as required:

   Auto-publish
   : In order to execute an API for testing purposes, you must make it online. To make the API online and auto-publish your API document, set the Auto-publish toggle to the On position.

   Target catalog
   : The Catalog to which you want to publish the Product that contains the API. The selected Catalog is used as the scope for the other preference settings. You can select a Catalog of your choice, or you can opt to use the Sandbox Catalog by selecting Use the default built-in Sandbox Catalog.

   Target Gateway service
   : The gateway service to which you want to publish the Product that contains the API.

   Target product
   : The Product that will contain the API; you can select any of the Products from the selected Target catalog, or you can opt to use an automatically generated Product by selecting Generate Product on Save. The auto-generated Product has the title *api_title* auto product.

   Target product rate limit
   : If you opted to use an automatically generated Product, you can configure a rate limit to control calls to the API. If you selected your own Product, the Target product rate limit option is not available; instead, the rate limits that are configured in the selected Product and Plan are applied.

   Target Plan
   : The Plan in the selected Product that you want the test application to subscribe to. If you opted to use an automatically generated Product, the Target Plan option is not available; instead, the application is subscribed to the Default Plan in the automatically generated Product.

   Test application
   : The application that you want to subscribe to the selected Plan. You can select an application of your choice or, if you opted to use the Sandbox Catalog, you can instead use the pre-supplied test application by selecting Use the built-in Test Application.

   Test Consumer Org
   : The consumer organization that you want to subscribe to the selected Plan. If you selected your own application, the consumer organization is preset to that which contains the application, and cannot be changed. If you opted to use the pre-supplied test application you can, if required, select a consumer organization of your choice.
   Click Reset to reset preferences to the default values.

4. Click Save Preferences when done.
   The Test page header displays the following details:
   - The target catalog.
   - The target gateway services.
   - The target product associated with the current API.
   - If the current status of API is Online or Offline. You can configure this in the API's Design page header.

Results

The next time you bring the API online, the API is published as specified by the preference settings, ready for testing.
Note: These settings are stored in your browser's local storage and will be used for your API testing in subsequent sessions. The following settings are specific to each individual API:

- Target product
- Target product rate limit
- Target Plan

The remaining settings will be applied to all your APIs.
Previous topic: Preparing an API for debugging with the Test tab
Next topic: Sending the API request

Sending the API request

Fill in fields to set up the request for an API that you want to debug on the Test tab.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Open the Test tab

1. Log in to API Manager or API Designer.
2. In the navigation list, click Develop, then select the APIs tab.
3. Click the title of the API that you want to test.
4. On the API Design page, click the Test tab in the page header.

Fill in the Request section

Use the Request section of the page to set up the request URL, the authentication mechanism, and the request parameters. Complete the following steps to fill in the fields that are needed for configuring the request.

Note: The Test tab does not support vanity endpoints; you must specify the gateway endpoint at which the API is invoked. The **Request** field uses the gateway endpoint by default.

1. To fill the Security scheme, complete the following steps:

a. Click Authorizations and select the security definition that you want. The available security definitions depend on the security schemes that are already configured in the API. To know how to configure security schemes, see Defining security schemes. The available security definitions are:
   - API key
   - Basic
   - OAuth

b. If your API definition uses API key authorization for the security setting, enter the necessary authorization details in the following fields on the Authorize page:

   Name
   : The variable name that is auto-populated from security scheme.

   Located In
   : Location is auto-populated from the security scheme.

   Value
   : The user can enter the value based on the auto-populated name. For example, if the name is X-IBM-Client-Id, the user can enter the same name in the value field.

   For more information on API key security schemes, see Defining API key security schemes.

c. If your API definition uses Basic authorization for the security setting, enter the necessary authorization details in the following fields on the Authorize page:

   Username and Password
   : Enter the username and Password that is needed for authenticating with the user registry.

   For more information on basic security schemes, see Defining basic authentication security schemes.

d. If your API definition uses OAuth authorization for the security setting, enter the necessary authorization details in the following fields on the Authorize page:
   Note:
   - The OAuth authorization supports only the native OAuth provider. For more information on native OAuth provider, see Configuring a native OAuth provider
   - The available flow options for OAuth authorization are:
     - Implicit
     - Access Code
     - Resource Owner - Password
     - Application

     The fields on the Authorize page are based on the configured flow. For example, in password flow, the Authorization URL field is not available.

   Authorization URL
   : This URL is used to redirect users for authentication and authorization. The URL is auto-populated from the OAuth Provider that you created in the Resources page.

   Name
   : The name of the OAuth provider is auto-populated.

   Client ID
   : This ID is used to authenticate and authorize the client's access to the resources. It is auto-populated based on the application that you selected under Target configuration. For more information, see Specifying the testing preferences for an API.

   Client secret
   : Enter the secret key corresponding to the Client ID. The client secret is displayed only once when you create the application. Note down the secret key for OAuth authorization.

   Flow
   : Flow in API authorization refers to the OAuth flow types that determine the process of obtaining authorization. It depends on the flow type that you select when you create the security scheme for the authorization. This field is auto-populated by default.

   Scopes
   : Select the check boxes of scopes that you want to add. The scopes are included in the access tokens that are generated from the OAuth provider. When an OAuth protected API is invoked, the gateway checks the scopes that are carried in the access tokens. Then it compares them against the list of allowed scopes in the security definition to determine whether to grant access.

   Token URL
   : This URL is used for obtaining OAuth tokens during the authentication process. The Token URL is auto-populated based on the URL that you add when creating the corresponding OAuth provider on the Resources page.

   Redirect URIs
   : Select the redirect URIs from the list.

   Username and Password
   : Enter the username and password of the user registry that is selected under the corresponding OAuth providers on the Resources page.

   Click Get Token to create the access token.

   The system automatically updates the access token in the Parameter tab when you apply authorization.

   For more information on OAuth security schemes, see Defining OAuth2 security schemes.

e. Click Apply.
   When you invoke the API, API Connect populates a header using the provided information.

2. Select an operation and request a URL from the list provided.
3. On the Parameters tab, define header, query, and path parameters.
   An empty row is provided for you to define parameters, enter the parameter name in the Key field, select query, header, or path in the Located in field as appropriate, and supply a string value in the Value field. As you begin to define a new parameter, a further empty row is added automatically.

   Default header parameters and values are provided. For example, if the API has client ID or client secret definitions applied, the corresponding keys are added as header parameters, with the values preset; for details on configuring client ID and client security definitions, see Creating an API key security definition.

   The following table lists some common header definitions that are used in a request:

Table 1. Common request headers

Key	Value	Comments

Key	Value	Comments
Accepts	*media_type/sub type*	Specify the type of content that the response headers should use. The default is **`application/json`**.
X-IBM-Client-Id	*client_ID_val*	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client ID of your application.
X-IBM-Client-Secret	*client_secret_val ue*	If you are using the built-in test application in the Sandbox catalog, the value is pre-populated automatically. If you are using your own client application, replace the value with the client secret of your application..
Authorization	Bearer *access_token*	Encode the token in base64. API Connect cannot encode the token for you.
Content-Type	*media_type/sub type*	Specify the type of content that the response body should use; for example, **`application/json`** or **`image/png`**.

If the API has path or query parameters defined, these are added to the parameters list, ready for you to supply values; for details on configuring path and query parameters, see Defining Paths for a REST API and Configuring an operation.

4. If the operation is POST or PUT, set up the request body.
   a. Click the Body tab.
   b. Type the information for the body of the request.

Send the request

When your API request is configured, click Send to execute the call.

If a message displays indicating "No Response", the API call cannot be completed. Possible causes of this problem are as follows:

- CORS is not enabled in the API's definition
  Edit the API's definition and enable CORS. Then, save the change and publish the API. If you are using your own client app, remember to subscribe it to the API again after publishing.
- The gateway service URL has an invalid certificate
  Follow the instructions to accept the certificate and continue testing.
- The browser cannot connect to the gateway service

Previous topic: Specifying the testing preferences for an API
Next topic: Reviewing the API response and trace

Reviewing the API response and trace

Review the response to an API that was invoked in the API Connect Test tab. You can use the included trace information to debug the API's execution.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

When the API request is invoked, the response displays in the "Response" section of the Test tab. The response always includes the HTTP status code the amount of time it took to receive a response. If the call completes (even if it returns an error), the response also includes headers and a body.

Click the Body tab to see the body of the response. When you review the body of the response, click the Parsed tab to view the response using the format that you specified in the "Accepts" request header. Click the Raw tab to view the unformatted response body.

Click the Headers tab to see the content of request headers and response headers.
Attention: If the assembly or back-end API returns a Cache-Control header, add the **`Cache-Control: no-store`** request header to prevent the browser from caching the request. Depending on your server, you might want to use the **`Cache-Control: no-cache`** header instead.
Click the Trace tab to display a record of the API execution so you can see what actions were triggered and the code that we executed for each action.

Examine the trace

Use the Trace tab to see exactly how the API call was executed. This is helpful when the call returned an error and you don't know why. You can debug the API by reviewing the trace to see each step of the API's execution.

Note: The Trace works only with the default Gateway's URL. You cannot select a different Gateway for the trace.
The Trace tab contains the following components to help you debug the API:

Process flow diagram
: In the diagram, the policies (actions) that were executed during the call are highlighted while the rest of the process flow is dimmed. The highlights make it easy to see where the executed actions occurred in the overall flow while clarifying the actual flow of execution for the call. For example, if the process flow includes a switch with three options, only the option that was selected during the call is highlighted.

Policies list
: A list of the highlighted policies lets you select a policy to examine its trace.

Advanced toggle
: The Advanced toggle that lets you control the level of detail in the trace. A basic trace shows the code for the input and output of the selected policy. An advanced trace shows the full code for the policy's execution.

Code box
: The selected level of code for the current policy displays in the code box, where you can review it in detail to see exactly how that policy was executed. By default, a minimal version of the response displays (the endpoint, the request, and the response, and the status message), with sections collapsed. You can expand individual sections by clicking the expand icon next to each. To see the complete response, click the Advanced toggle.

Previous topic: Sending the API request

Next topic: Testing a GraphQL API with the Test tab

Testing a GraphQL API with the Test tab

For a GraphQL API definition, the Test tab contains a GraphiQL editor. You can use the GraphiQL editor to help construct a GraphQL query. When you test your GraphQL API, the response is displayed in the GraphiQL editor.

You can test a GraphQL query in either of the following ways:

- Use a `POST` operation, in which case the query is sent in the body of the operation request.
- Use a `GET` operation, in which case the query is sent as a query parameter.

For each operation type, you can test the query against either the GraphQL API endpoint itself, or against the cost endpoint that returns details of the cost of a request to the GraphQL API endpoint.

Whichever method and endpoint you use, you can either supply the query directly, or you can use the GraphiQL editor to help construct the query; the editor provides type ahead assistance based on the schema that is defined for the API, and highlights errors along with correction suggestions. The schema was initially uploaded when the GraphQL API definition was created, but might have been modified subsequently. For details on creating a GraphQL API definition, see Creating a GraphQL proxy API. For details on modifying the schema, see Using the GraphQL schema editor.

Before you begin

See Preparing an API for debugging with the Test tab for the requirements that your API definition must meet for you to test it with the Test tab.

Procedure

1. In the Request section, select the required operation type and endpoint; for example:
   - `POST https://myserver.com/myorg/sandbox/mybasepath/graphql`
   - `GET https://myserver.com/myorg/sandbox/mybasepath/graphql/cost`
2. On the GraphiQL tab, in the left hand pane of the editor, supply the query; for example:

```
{
  accounts(limit: 100) {
    name {
      first
      last
    }
  }
}
```

3. If required, you can supply additional request headers on the Parameters tab.
4. If your query includes variables, you can supply values for the variables in the Query Variables pane. For example, if the query is as follows:

```
query MyQuery($Query__accounts__limit: Int)
{
  accounts(limit: $Query__accounts__limit) {
    name {
      first
      last
    }
  }
}
```

   you can set a value for the `Query__accounts__limit` by entering the following in the Query Variables pane:

```
{
  "Query__accounts__limit": variable_value
}
```

   where *variable_value* is the required value.
5. Click either Send, or the Execute Query icon ▶ in the editor. The response is displayed in the GraphiQL editor, and the Trace section shows you how the API call was executed. For details on the trace information, see Examine the trace.

Previous topic: Reviewing the API response and trace

Testing an API with Automated API behavior testing

Use the IBM® Automated API behavior testing application to invoke an API from outside of the API Connect Assembly page so that you can verify that it executes properly.

Automated API behavior testing provides a simple set of fields where you can quickly invoke your API through automation.

Automated API behavior testing is an optional add-on to API Connect, and must be deployed by your administrator. If Automated API behavior testing is available in your deployment, a Test API displays on the Home page in API Manager.

If you want to use Automated API behavior testing for validating an API, complete the following steps to get started.

1. Log in to API Manager.
2. Activate your API to make sure that it's available online.
3. Create a client application and copy its client ID and client secret.
4. Subscribe the client app to the API.

5. Click API Manager in the banner to return to the Home page, and then click the Test API tile.

Getting started

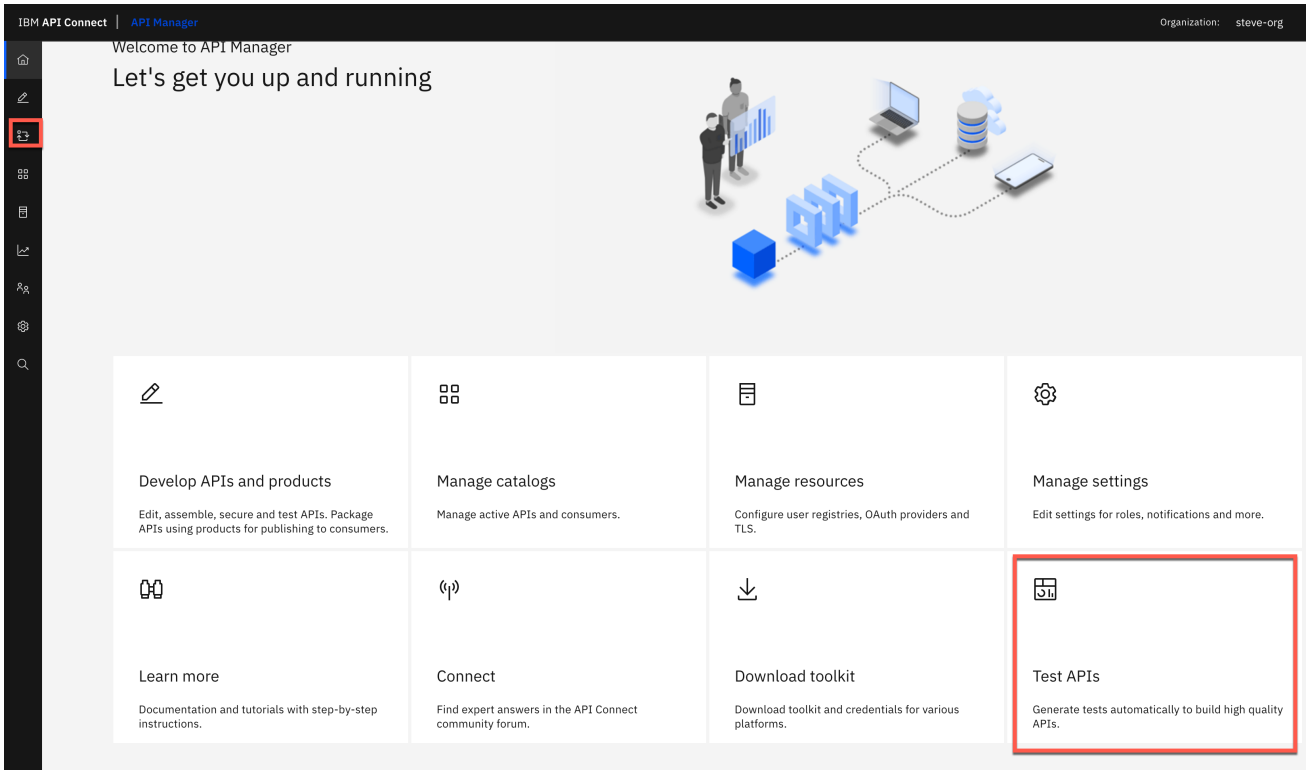
The Automated API behavior testing interface provides collaborative and powerful API testing capabilities.

- **Create automated and simple to use API tests quickly and easily.**
  - Produce high quality APIs consistently, with automated and simple to use API testing that you can rely on.
- **Intelligent validation of API payload accuracy.**
  - Add more intelligence to your tests to verify the accuracy of the payload. You can easily make logical assertions to create flexible and powerful conditions for validation, with no code necessary.
- **Collaborative testing.**
  - Accelerate your API development and testing, by sharing your tests and results.
- **Easily integrate into your CI/CD pipeline to execute tests as part of your deployment.**
  - Create API Hooks to allow your tests to be run via the command line and become part of your automated build processes.
- **No code necessary.**

How to get started

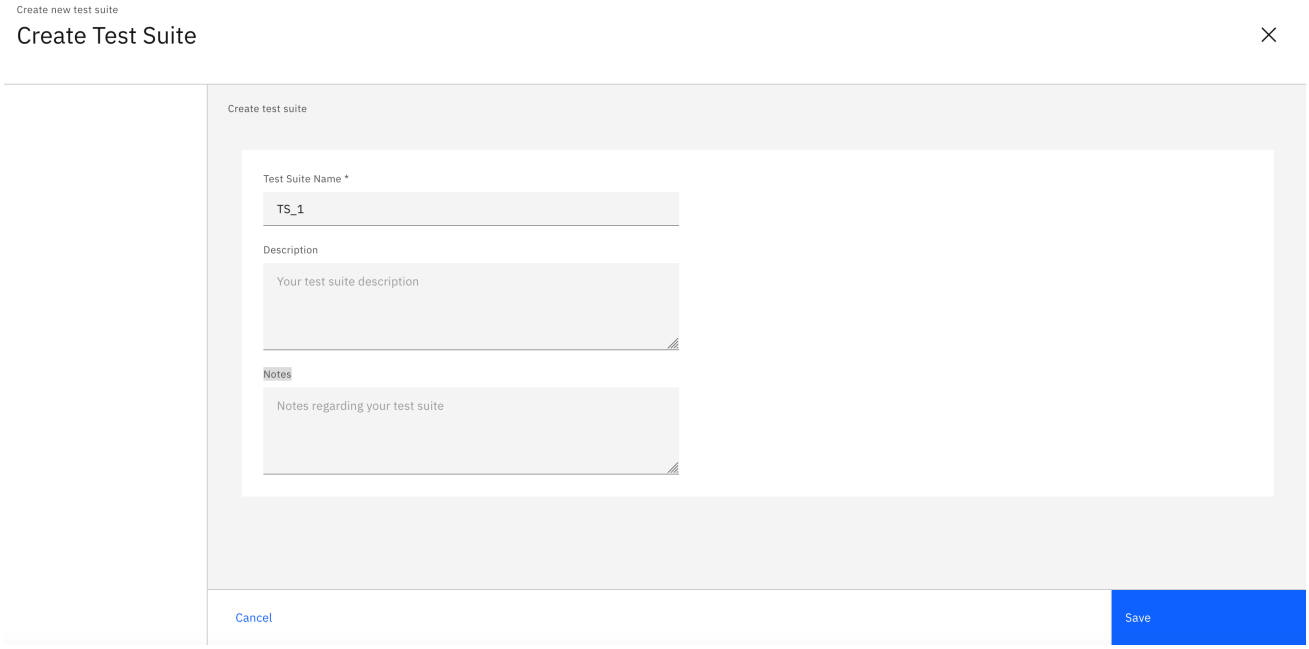
Creating a test involves the following steps:

1. Creating a test suite
2. Creating test cases in a test suite
3. Defining variables
4. Running the test
5. Publishing the test



Explore the following tasks for detailed instructions:

- Creating a test suite
- Modifying a test suite
- Deleting a test suite
- Creating a test case
- Modifying a test case
- Defining variables
- Deleting a test case
- Running a test case
- Viewing the test report
- Publishing a test



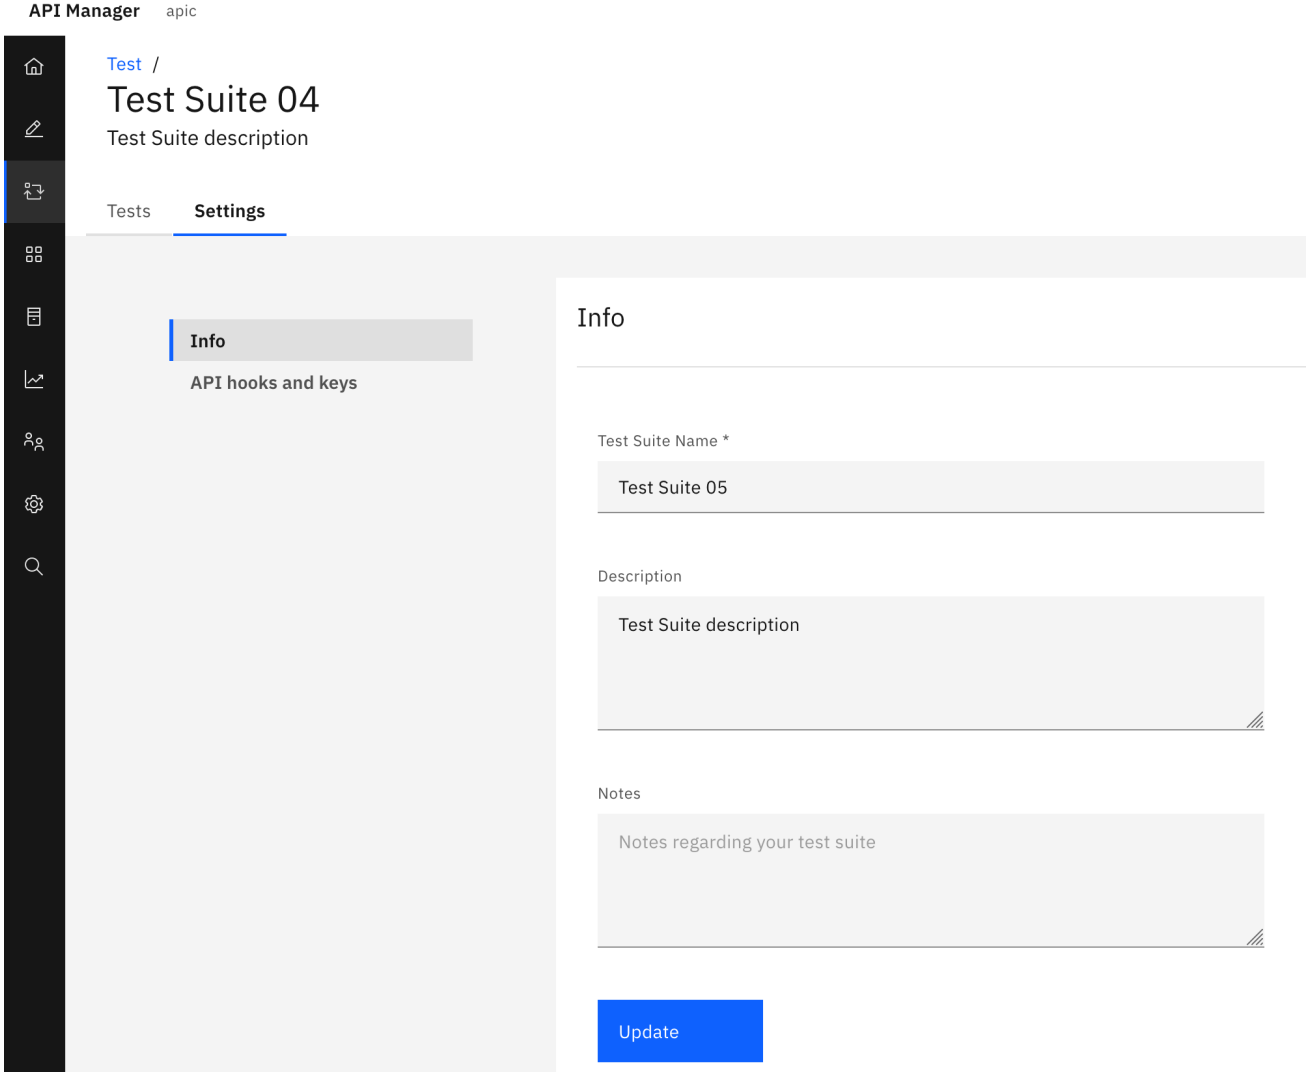
Creating a test suite

The following instructions show you how to create a test suite using the **API Manager**.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.

3. On the Test page, click **Add test suite**.

4. In the Create Test Suite page, enter a test suite name, description, and any relevant notes for the test suite.
5. Click **Save**. Once the test suite is created, you can add multiple test cases.



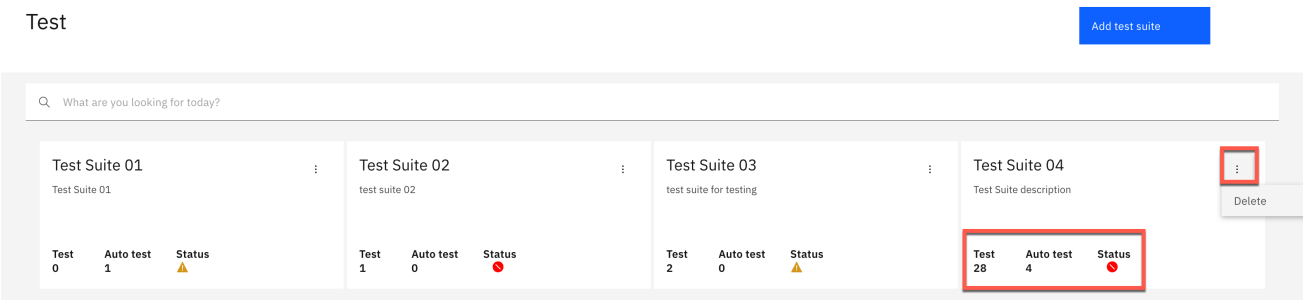
What to do next

- Next topic: Creating a test case

Modifying a test suite

The following instructions show you how to modify a test suite using the **API Manager**.

1. Log in to the API Manager.
2. Click the Test APIs tile.
3. Select a test suite to modify.
4. Go to the **Settings** tab.



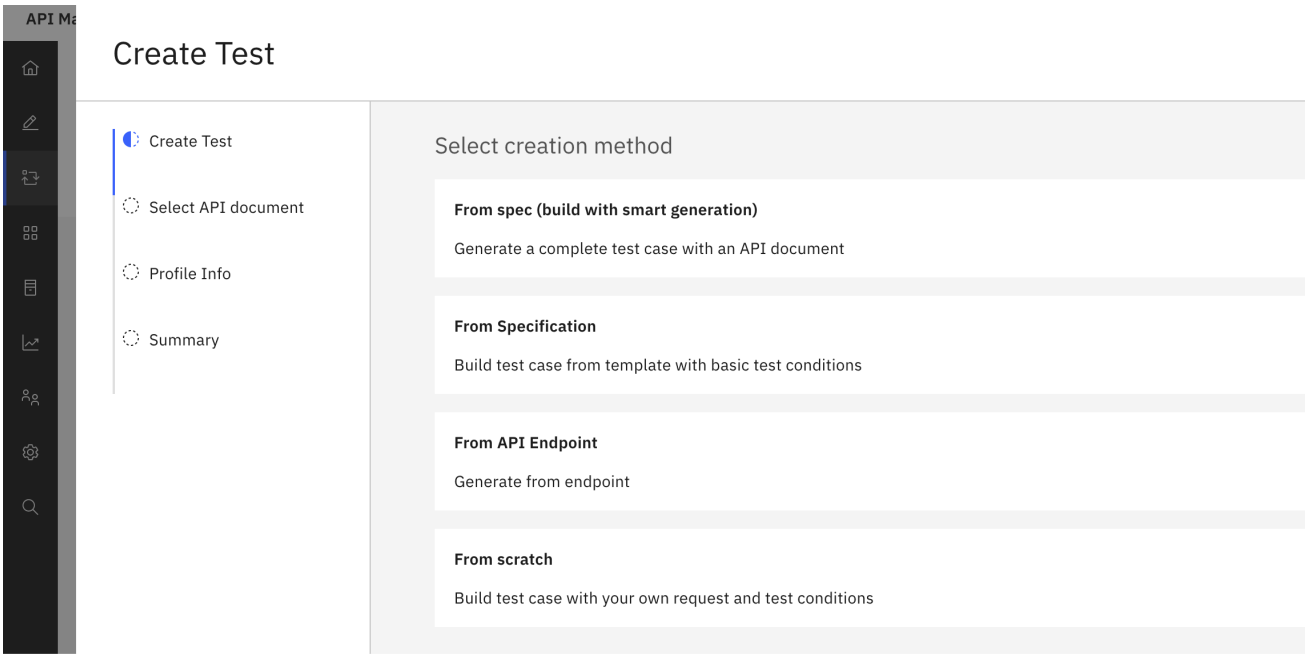
5. In the **Info** tab, update the following:
   - Test Suite Name
   - Description
   - Notes
6. Click **Update**.

- Next topic: Modify a test case

Deleting a test suite

To delete a test suite, complete the following steps:

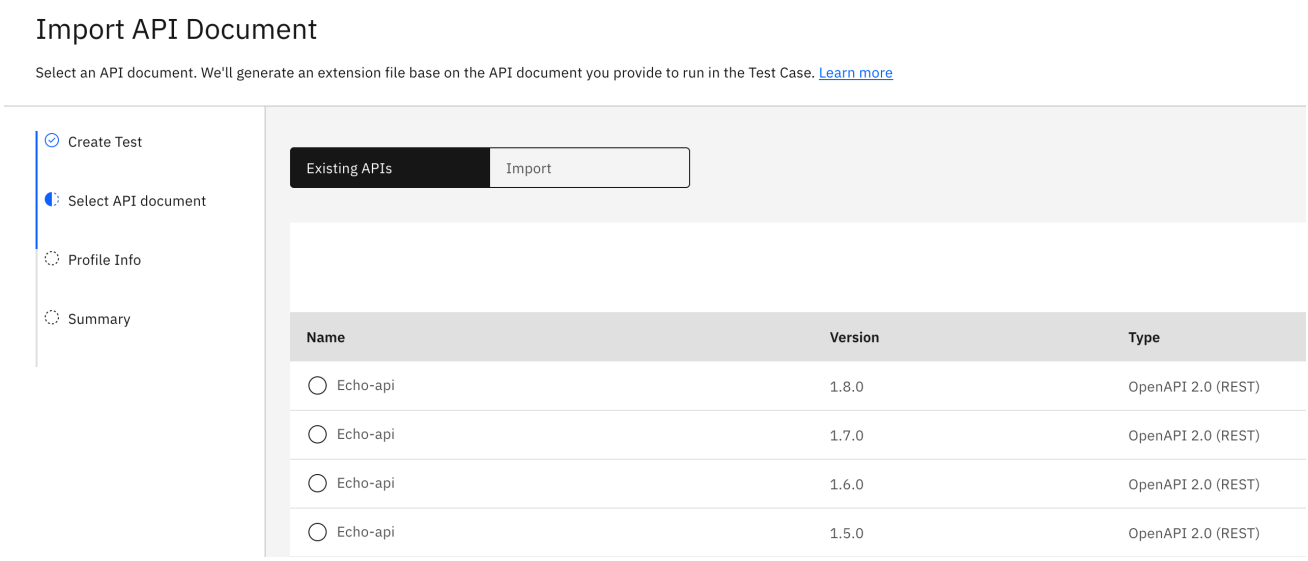
1. Login to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, locate the test suite you want to delete and determine whether it contains any tests by observing the displayed **Test** count.



Note: You can't delete a test suite that contains tests, so if your test suite does contain any tests you must delete them first; see Deleting a test.

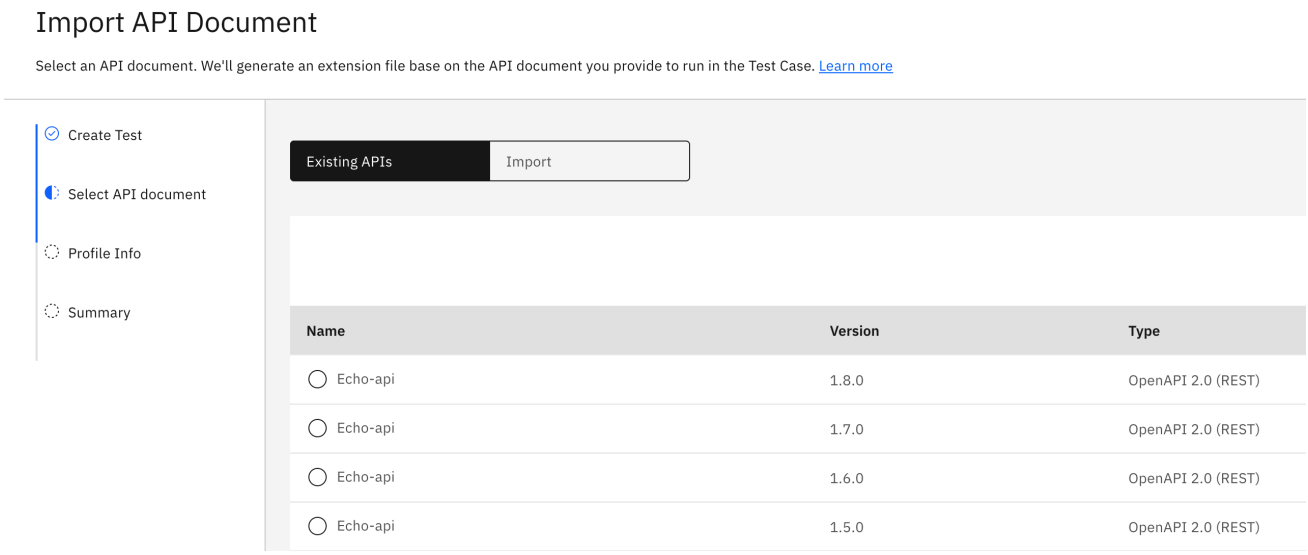
4. To delete the test suite, click its **Options** icon, then click **Delete**.

Creating a test case



The following instructions show you how to create a test case using the **API Manager**.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. In the Create Test page, go to the **Tests > Test Cases** tab, and click **Add**.
5. Select a test case creation method:

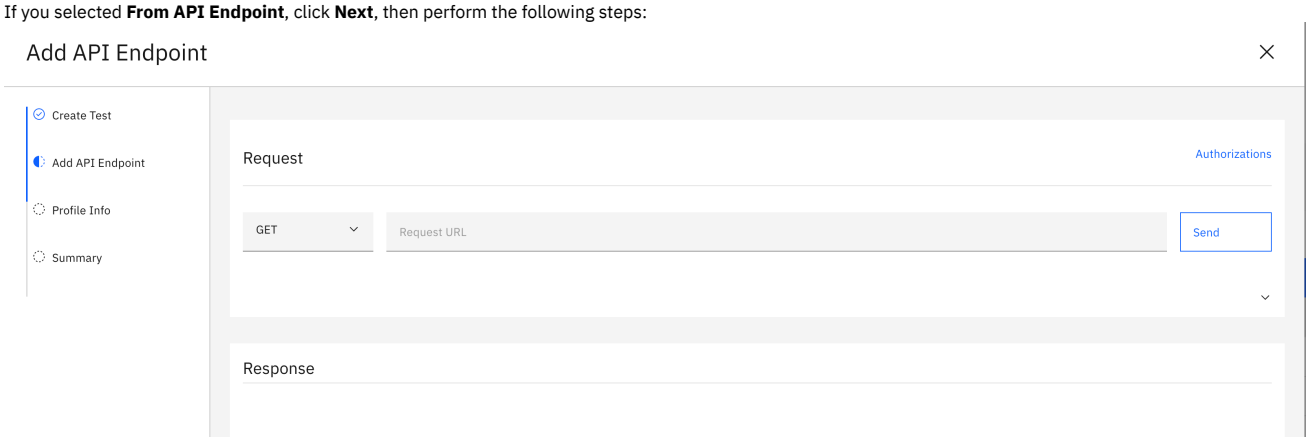


- From spec (build with smart generation): Generates a complete test case that leverages NLP to help developers and QAs test their APIs effectively in an efficient way
- From Specification: Builds test case from OpenAPI specification
- From API Endpoint: Generates test case from a specified endpoint
- From scratch: Creates a test case with your own request and test conditions

6. If you selected **From spec (build with smart generation)**, click **Next**, then perform one of the following steps:

1. Go to the **Existing APIs** tab:
    1. Select a predefined API.
    2. Click **Next**.
    3. Select a path.
    4. Enter the API name.
    5. Provide a brief description.
    6. Add tags.
    7. Click **Next**. You will see the message that the test case has been generated.
    8. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
    9. Click **Save**.
    10. Click **Run Test**.
2. Go to the **Import** tab, do one of the following:
    - Drag and drop a JSON or YAML file that has the API test case definition OR
    - Enter an URL for the API test case. Provide username, and password if required, for authentication.
    1. Click **Next**.
    2. Select a path.
    3. Enter the API name.
    4. Provide a brief description.
    5. Add tags.
    6. Click **Next**. You will see the message that the test case has been generated.
    7. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
    8. Click **Save**.
    9. Click **Run Test**.

7. If you selected **From specification**, click **Next**, then perform one of the following steps:



1. Go to the **Existing APIs** tab:
    1. Select a predefined API.
    2. Click **Next**.
    3. Select a path.

4. Enter the API name.
5. Provide a brief description.
6. Add tags.
7. Click **Next**. You will see the message that the test case has been generated.
8. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
9. Click **Save**.
10. Click **Run Test**.

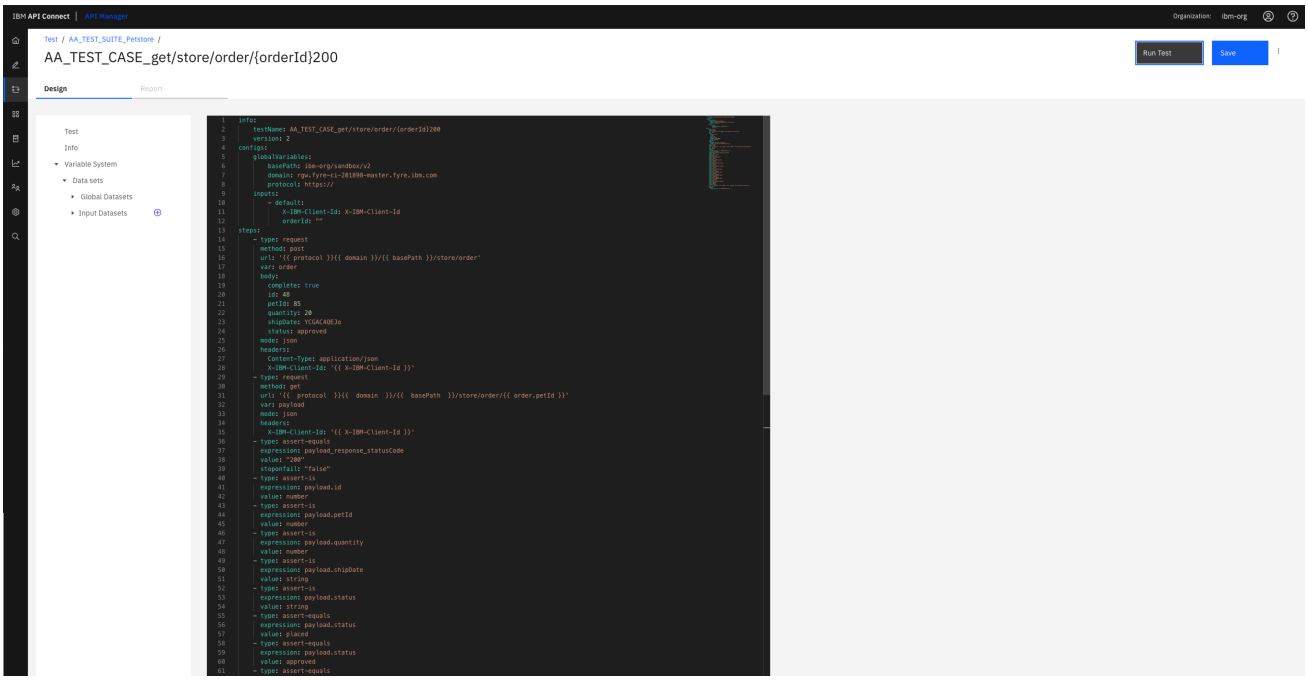
2. Go to the **Import** tab, do one of the following:
   - Drag and drop a JSON or YAML file that has the API test case definition OR
   - Enter an URL for the API test case. Provide username, and password if required, for authentication.
   1. Click **Next**.
   2. Select a path.
   3. Enter the API name.
   4. Provide a brief description.
   5. Add tags.
   6. Click **Next**. You will see the message that the test case has been generated.
   7. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
   8. Click **Save**.
   9. Click **Run Test**.

8. If you selected **From API Endpoint**, click **Next**, then perform the following steps:

   1. In the Request section, select a method, enter the API endpoint that was generated when you published the API, set the authorization if required, and click **Send**. You will see the response in the **Response** section.
   2. Click **Next**.
   3. Enter the test name, description, and tags, then click **Next**. You will see the message that the test case has been generated.
   4. Click **Edit**. You will see the generated test assertions. You may edit the test assertions as needed.
   5. Click **Save**.
   6. Click **Run Test**.

9. If you selected **From scratch**, click **Next**, then perform the following steps:

   1. Enter the test name.
   2. Provide a brief description.
   3. Add tags.
   4. Click **Next**. You will see the message that the test case has been generated.
   5. Click **Edit**.
   6. Enter the API definition. Refer to the Test Defintion Syntax for a sample.
   7. Click **Save**.
   8. Click **Run Test**.



What to do next

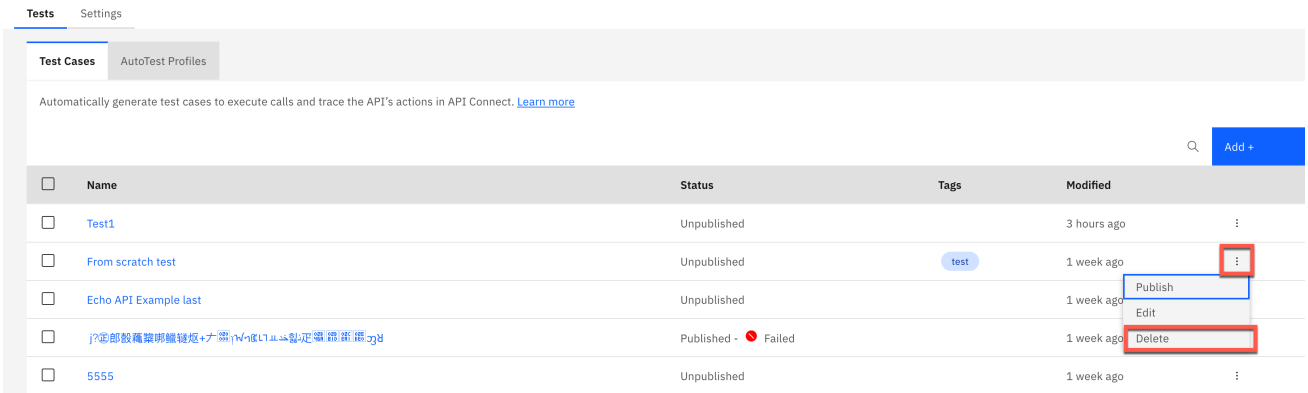
- Next topic: Modifying a test case

Modifying a test case

The following instructions show you how to modify a test case using the **API Manager**.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, click a test suite tile.
4. Select a test case you wish to edit.
5. Go to the **Design** > **Test** tab, modify the API definition as needed, and click **Save**.

6. To run the test case, click **Run Test**.
7. To update the test case name, description, and tags, go to the **Info** tab, then click **Save**.
8. To update the global or input datasets and modify the request payload, go to the **Variable System** > **Data Sets** > **Global Datasets** or **Input Datasets** tab. Then run the test case for each input dataset.



What to do next

- Next topic: Running a test case

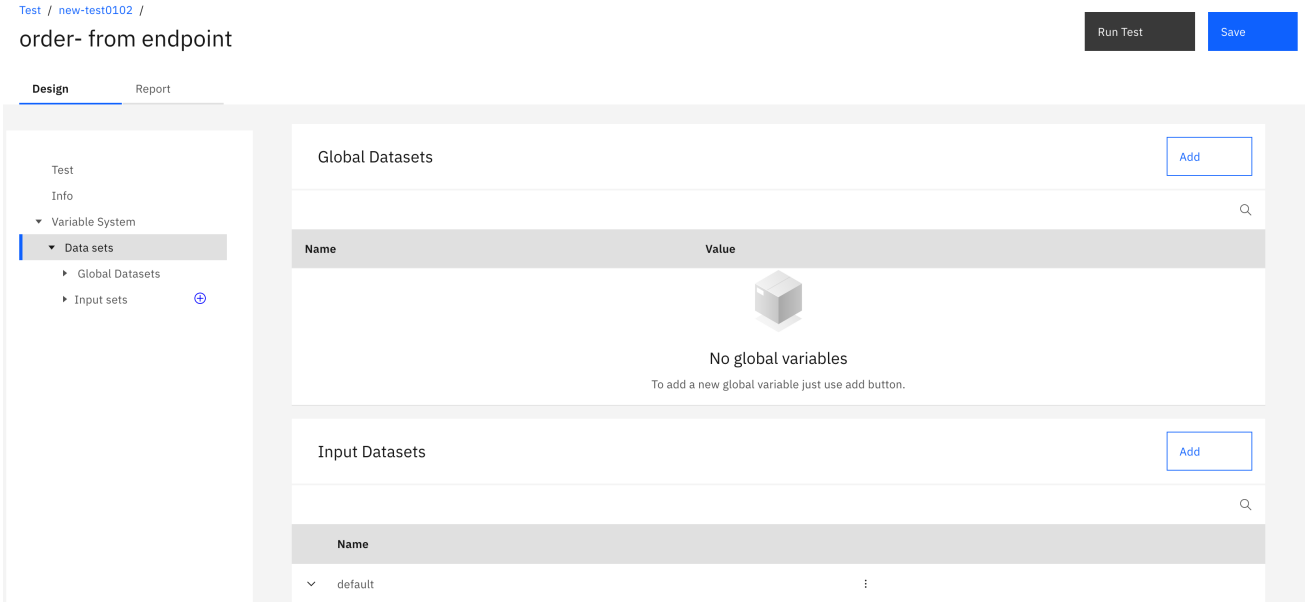
Deleting a test case

To delete a test case, complete the following steps:

1. Login to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. On the **Tests > Test Cases** tab, locate the test case you want to delete and click the **Options** icon > **Delete** option.

5. Click **Yes** for confirmation.

Defining variables

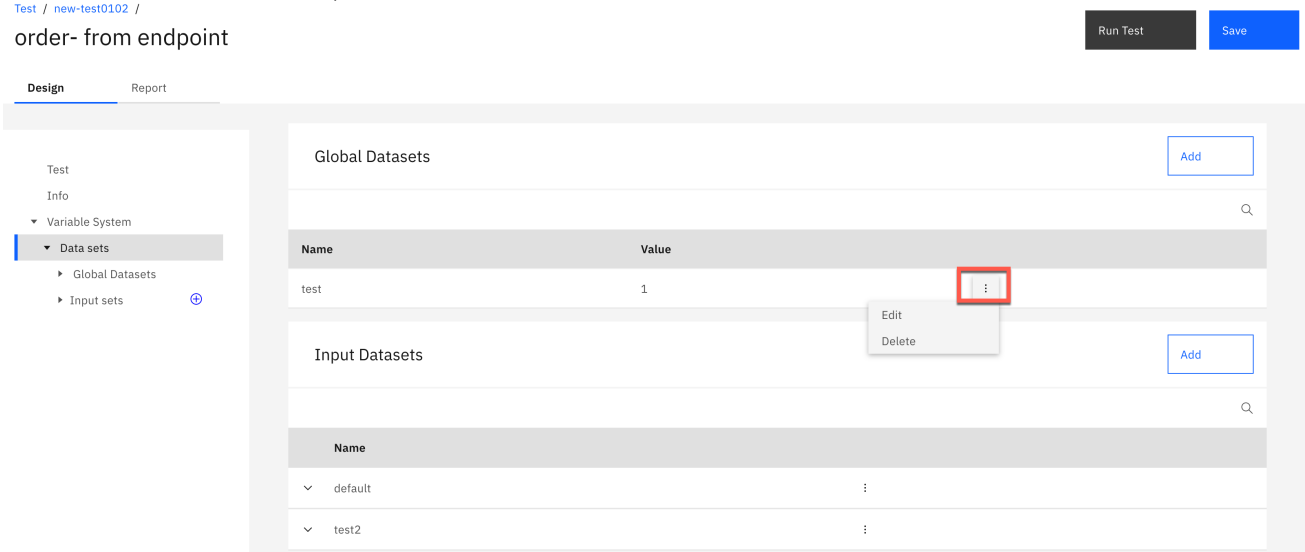


Within API Testing there are multiple ways to define variables to address different requirements.

Global Datasets

Global Datasets are ones that are common across the whole test and typically does not change between runs based on Input Datasets

Adding a global variable

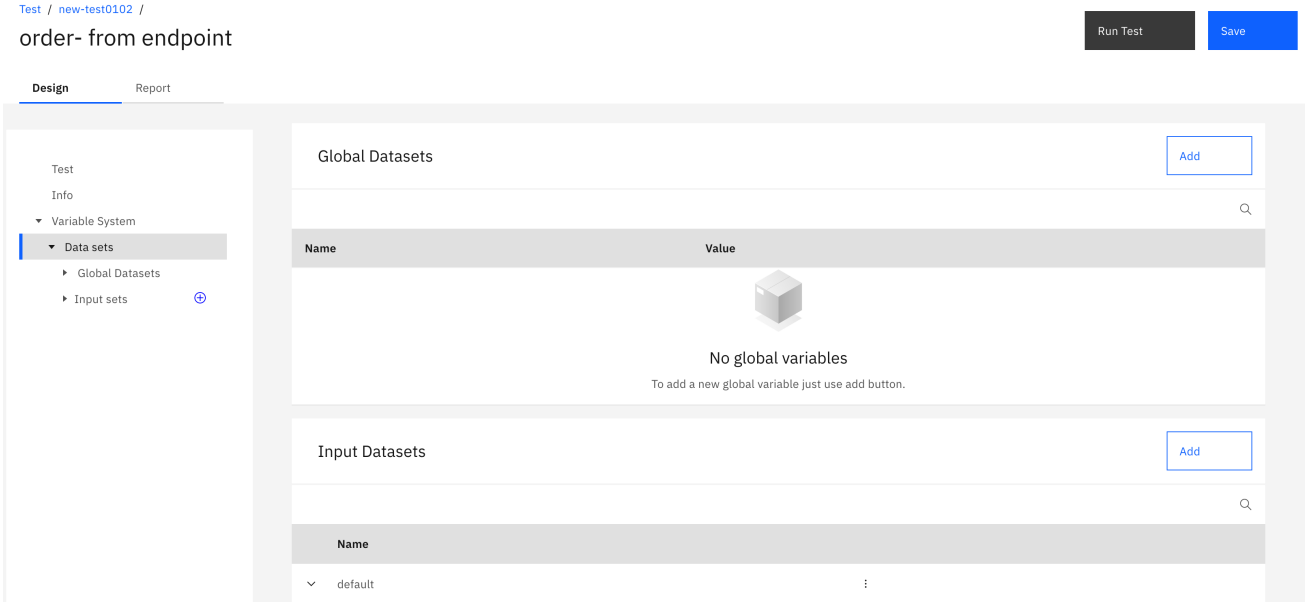


1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite tile.
4. Select a test case.
5. Go to the **Design** > **Variable System** > **Data sets** tab.

6. In the Global Datasets section, click **Add**.
7. Enter the variable name and value.
8. Click **Add**.

Editing or deleting a global variable

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite tile.
4. Select a test case.
5. Go to the **Design** > **Variable System** > **Data sets** tab.
6. In the Global Datasets section, click the options menu and select **Edit**.



7. Update the name and value as needed.
8. Click **Add**.
9. To delete a variable, click the options menu and select **Delete**.

Input Datasets

The input datasets, is a group of input variables representing a scenario (e.g product id). Where the number of input datasets determines how many times the test will be executed using those values. If 3 input datasets are defined, the test will run 3 times using the inputs defined within each of those sets on each run.

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite tile.
4. Select a test case.
5. Go to the **Design** > **Variable System** > **Data sets** tab.

6. In the Input Datasets section, click **Add**.
7. Enter a dataset name.
8. Click **Add**.

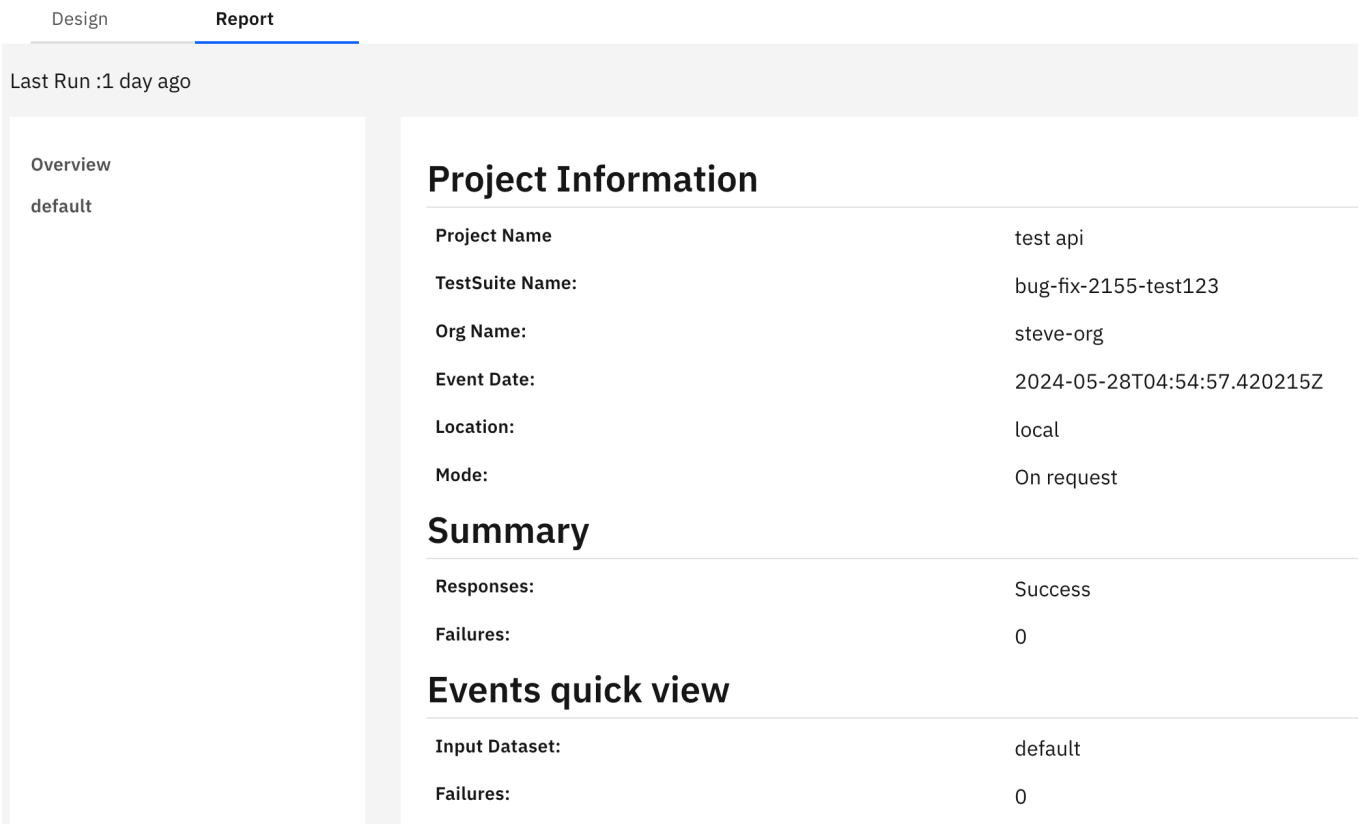
What to do next

- Next topic: Running a test case

Running published test cases

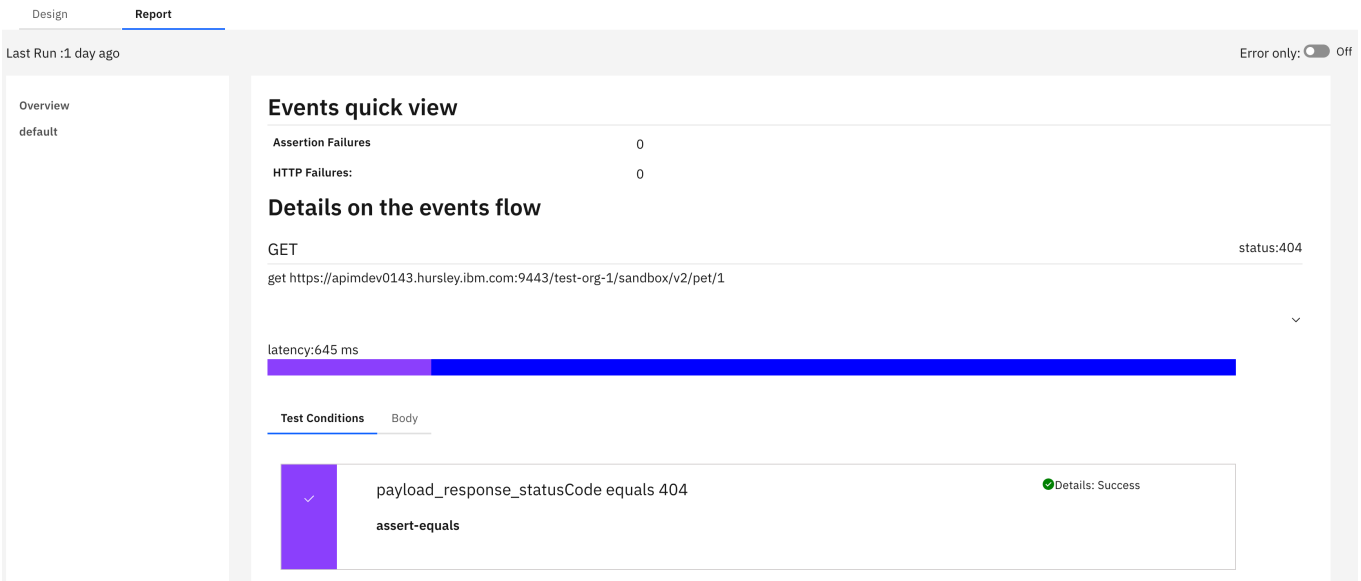
The following instructions show you how to run mutliple test cases that are published using the **API Manager**. To run a single test case, perform the steps as shown in Modifying a test case.

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, select a test suite tile.
4. To run multiple test cases, in the **Tests** > **Test cases** tab, select test cases with the status as **Published**, and click **Run**.



What to do next

- Next topic: Viewing a test report



Viewing a test report

Once a test run has completed (either stopped manually or the configured time to run threshold has been reached) you will be presented with the **Report** section, where you will be able to view the results of the run.

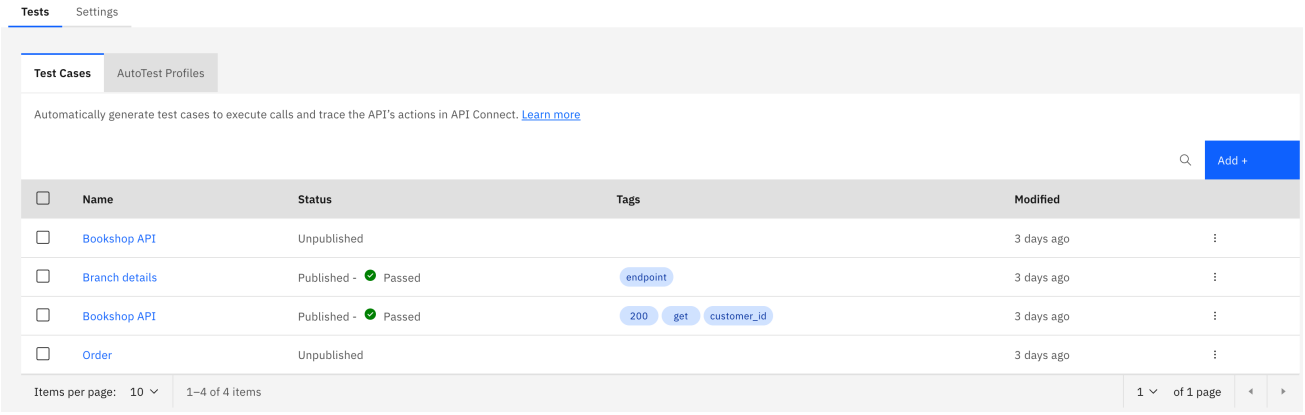
First up is the **Overview** tab, which contains information about the test case. The project Information section details the test case, while the Summary section gives the overall test run status, indicating success or failure and the number of failures, if any. The Events quick view section offers insights into the failures associated with each input dataset

The second tab presents detailed results for each input dataset offering a comprehensive view of the test outcomes for each specific input. The table contains the list of the calls and their respective response statuses.

*Both views allow you to apply **Errors Only** filter using the toggle button. This filter displays only the failed test conditions.*

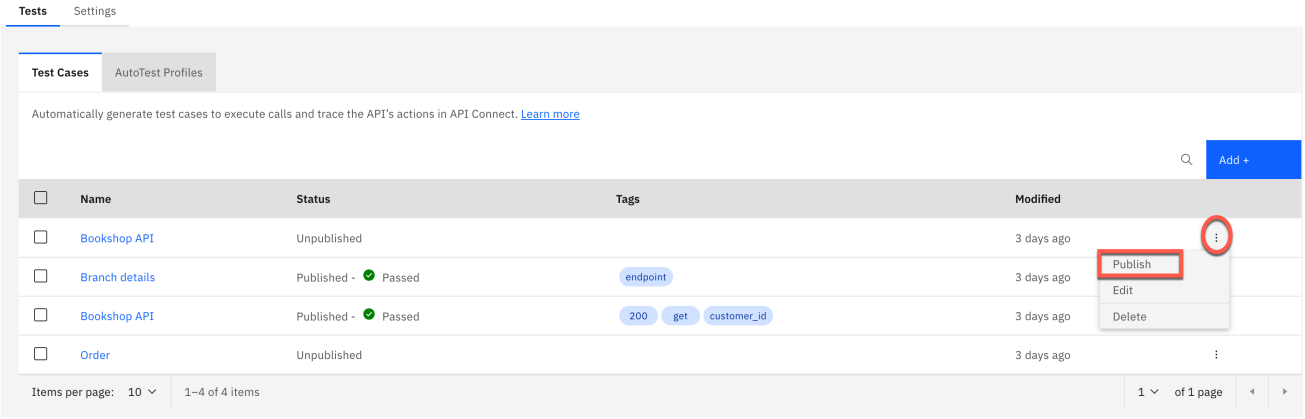
To download the report, click the options menu and select **Download Report**.

What to do next



- Next topic: Publishing a test

Publishing a test case



Once you have completed the configuration of your test, and run it manually to confirm that it works correctly, you can publish the test. After publishing, you have the option to select the published test case from the table, make changes using the editor, and publish it again.

To publish a test, complete the following steps:

1. Log in to the API Manager.
2. On the Home page, click the **Test APIs** tile.
3. On the Test page, select a test suite. A list of tests are displayed. If your test has not been published before, the status shows as **Unpublished**.

4. Select a test that you want to publish by clicking the **Options** icon and selecting **Publish**.

What to do next

- Next topic: Tagging a test

Tagging a test

Adding tags to your tests is an easy way to keep them organized in your Test Suite. Furthermore, tags can be used as a way to selectively execute certain tests in your test suite when running them via an API Hook (see Run Published Tests by Tag for more information).

Note: You can tag a test, while creating a test or after creating a test.

Adding a tag to a test

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite tile that contains the test that you want to tag.
4. Click the test case you want to edit.
5. To add tags to your test, go to the **Design > Info** tab and start typing the tag name in the Tags box. You can assign multiple tags to a test. To remove a tag, click the **x** button next to the tag.

6. Click **Save**. Tags can be viewed any time in the **Tests > Test Cases** tab.

What to do next

- Next topic: API Hooks

API Hooks

In addition to viewing and executing tests within the IBM API Connect Test interface, you may also perform these actions via an API. This allows tests to be executed via the command line, through third-party applications, or as part of a CI/CD pipeline. API hooks form the basis of this API, providing a base URL on which subsequent API operations can be performed. To start using an API Hook, see:

- Creating An API Hook.

API Hooks require authentication to use in the form of an API Key and Secret. Once you have created your API Hook, view the following page to learn how to create an API Key and Secret for your Test Organization:

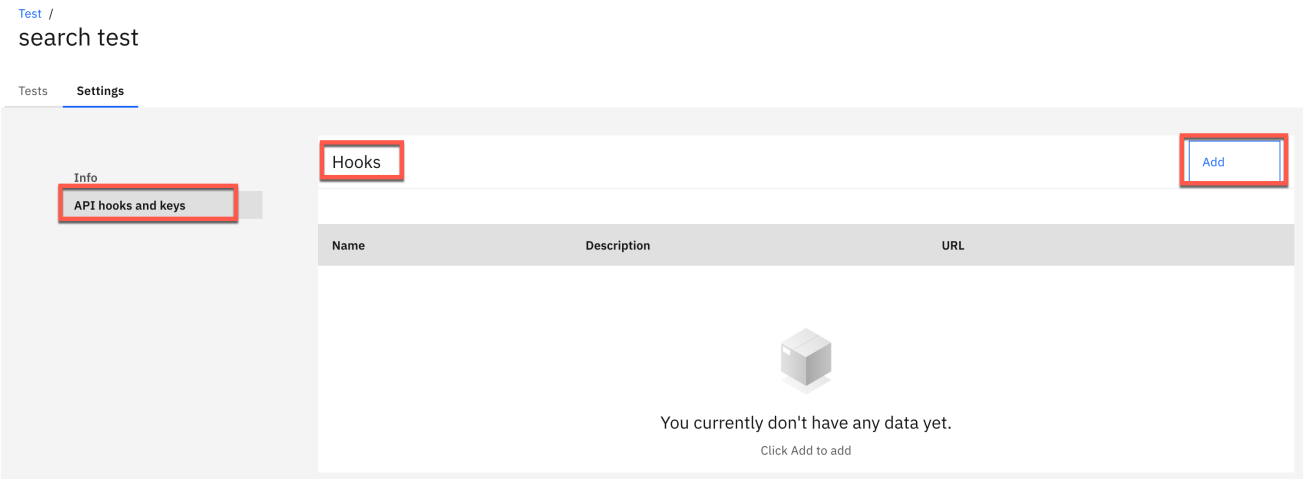
- Creating API Keys and Secrets

Once you've set up your API Hook, Key and Secret, see:

- Using API Hooks

Creating an API Hook

You can generate an API hook for each of the Test Suites within your Test Organization. API hooks are scoped to only one test suite and thus will only have access to operate on the data within that test suite; that is, if an API Hook is generated for **`Test Suite 1`**, it may only access the tests and test results associated with **`Test Suite 1`**. If you wish to interact with tests in multiple test suites, you will need to generate an API hook for each Test Suite.



API Hooks are protected and require an API Key and Secret to be used. You can find out how to create a API Key and Secret here.

If there are no Test Suites here, you can create one by clicking the **Create Test Suite** button after the Test Status chart.

How to create an API Hook

1. Log in to the API Manager.
2. Click the Test APIs tile.
3. Select a test suite.

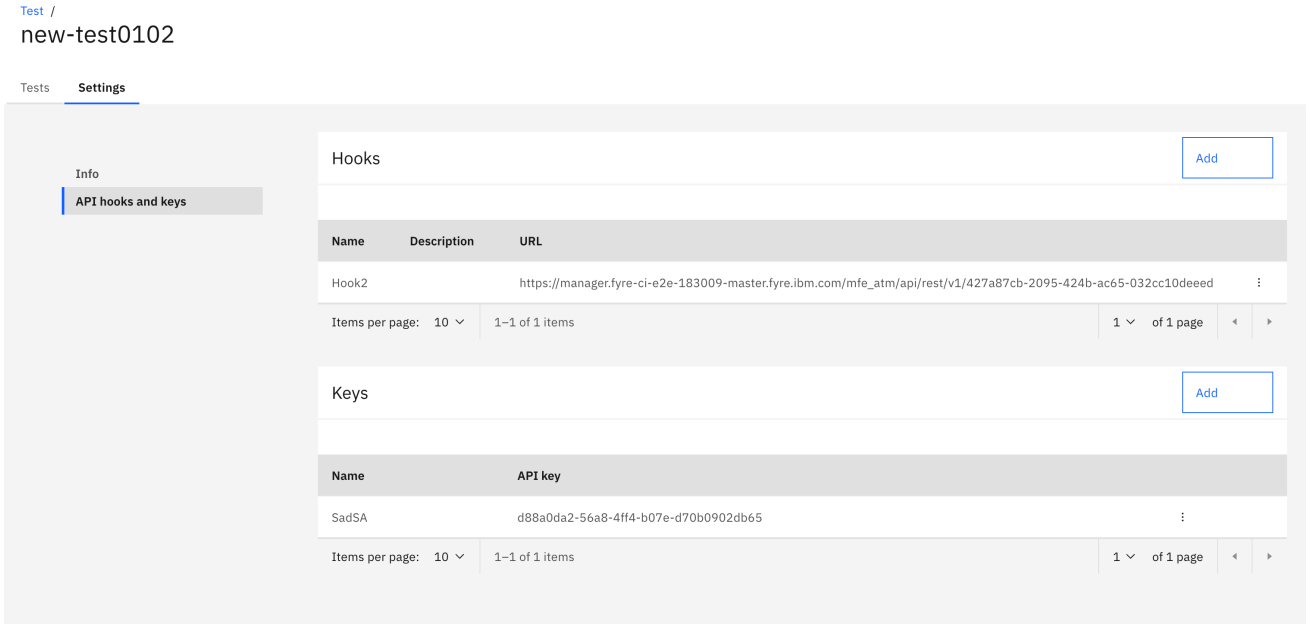
4. Select the **Settings** > **API hooks and keys** tab.

- Go to the Hooks section, and click **Add**.
- Enter name.
- Enter description.
- Click **Save**. You've now created the API Hook URL for your Test Suite. Make a note of this URL as this will form the base path of all future API requests you make to to this test suite. Close the Hook URL dialog box. You can see that your new API Hook is now in the list of API Hooks. You can click on this at anytime to view the URL again in the future should you need. Note that this URL will remain active until it is deleted. To delete the API Hook, simply click on the **Delete** icon next to the API Hook you want to remove.

What to do next

- Next Topic: Creating API Keys and Secrets

Creating API Keys and Secrets



API Keys and Secrets are the credentials required to use an API Hook. For a request to an API Hook to be authorised, both the **`X-API-Key`** and **`X-API-Secret`** headers must be provided. The values of the API Key and Secret represent the values of these headers respectively.

Unlike API Hooks which are scoped to a single Test Suite, API Keys and Secrets are scoped to a Test Organization. Therefore, any API Key and Secret pair which is generated within a Test Organization will have permission to authorise requests to all API Hooks within the same organization, regardless of the Test Suite the API Hook is associated with.

How to create an API Key and Secret

1. Log in to the API Manager.
2. Click the Test APIs tile.
3. Select a test suite.
4. Go to the **Settings** > **API hooks and keys** tab.

5. To use your new API Hook, you need to ensure you have an API Key and Secret.

   - Go to the Keys section and click **Add**.
   - Enter the key name.
   - Click **Save**. The system will display the key and the secret. Copy it for future reference. if your Key and Secret is set up, see Using API Hooks for more information on how to use the API Hook.

Your new API Key is now active and will now appear in the list of API Keys in the navigation menu. Clicking on the key will show you the API Key's value should you need to reference this again in the future. If you want to remove the API Key at any point, simply click on the **Delete** icon next to the API Key you want to remove. This will invalidate all future requests to API Hooks using this Key and Secret combination.

What to do next

- Next Topic: Using API Hooks

Using API Hooks

API Hooks provide a mechanism to interact with tests within a Test Suite via an API. Whilst the API Hook itself defines the basepath of this API, it also exposes a series of endpoints which, when appended onto this basepath, allow you to list and execute published tests within the API Hook's scope. The following pages detail these endpoints and subsequent parameters you can provide to either list, execute all, or execute only specific tests within a test suite.

Endpoints

- List All Tests
  Lists all of the published tests within an API Hook's scope.
- Run All Published Tests
  Runs all of the published tests within an API Hook's scope.
- Run Published Tests By Tag
  Runs the published tests within an API Hook's scope that match the tags specified in the request body.
- Run Published Test By ID
  Run a specified test within an API Hook's scope.

List All Tests

Description

The List All Tests endpoint lists all of the published tests within an API Hook's scope.

HTTP Request

```
GET <API-Hook-URL>/tests
```

Sample Method Invocation

```
curl -X GET \
-H X-API-Key:{API-Key} \
-H X-API-Secret:{API-Secret} \
<API-Hook-URL>/tests
```

Parameters	**Header Parameters** API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.
Response Content	**MIME type: application/json** `[ { testId: string, testName: string, testDescription: string, lastModified: string, authorName: string, tags: array[string] } ]` **Response Description** • `testId` ◦ ID of the test. • `testName` ◦ Name of the test. • `testDescription` ◦ Description of the test. • `lastModified` ◦ Date and time the test was last modified. • `authorName` ◦ User who composed the test. • `tags` ◦ Array of tags associated with the test.
Status Codes	200: Success 400: Missing Authorization Headers 401: Invalid Authorization Headers

Run All Published Tests

Description

The Run All Tests endpoint executes all of the published tests within an API Hook's scope.

HTTP Request

```
POST <API-Hook-URL>/tests/run
```

Sample Method Invocation

```
curl -X POST \
-H X-API-Key:{API-Key} \
-H X-API-Secret:{API-Secret} \
```

```
    -H Content-Type:application/json \
    -d '
        {
          "options": {
              "allAssertions": boolean,
              "JUnitFormat": boolean
          },
          "variables": {
              string: string,
          }
        }
      ' \
    <API-Hook-URL>/tests/run
```

Parameters	Header Parameters API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.
Request Body	**MIME type: application/json** `{ options: { allAssertions: boolean, JUnitFormat: boolean }, variables: { string: string, } }` **Body Parameters** • `options` (Only required if providing a child element) ◦ A wrapper object for the containing options on how what data should be returned in the response, or how the response should be formatted. ◦ Child Elements: ▪ `allAssertions` (Optional) ▪ When `false`, only the results of failing assertions in the test are returned. When `true`, all assertions in the test are returned. `allAssertions` is `false` by default. ▪ `JUnitFormat` (Optional) ▪ When `false`, `application/json` format is returned for the test results. When `true`, `text/xml` JUnit format is used for the test results (see `text/xml` response). `JUnitFormat` is `false` by default. • `variables` (Optional) ◦ The variables section is used to pass a list of named variables and their values into the tests being run. It is only used by tests that have been written to make use of variables, and have values stored alongside them. Declaring the variable name as the object key, and its new value as the key's value (as type string), will overwrite the current value of the variable in the test which shares its name with the object key.
Response Content	**MIME type: application/json** `application/json` is the default response from the endpoint. `[{ testRunId: string, testId: string, testName: string, location: string, initiated: string, duration: integer, status: enum['passed' or 'failed'], reportUrl: string, results: { warningsCount: integer, failureCount: integer, httpFailures: array[object], criticalFailures: array[object], assertions: array[object] } }]` **Response Description**

- `testRunID`
  - ID of the test run.
- `testId`
  - ID of the test which was executed.
- `testName`
  - Name of the test.
- `location`
  - Location of the agent which excuted the test.
- `initiated`
  - Date and time when the test was initiated.
- `duration`
  - Total duration of the test run in seconds.
- `status`
  - Overall result of the test.
- `reportUrl`
  - URL to the test run report.
- `results`
  - A wrapper object containing the results of the test run.
  - Child Elements:
    - `warningsCount`
      - Count of the HTTP warnings returned by the test assertions.
    - `failureCount`
      - Count of the HTTP status code responses that are greater than 400.
    - `httpFailures`
      - Description of failures whose HTTP Status response code is greater than or equal to 400.
    - `criticalFailures`
      - Description of failures whose HTTP Status response code is greater than or equal to 500.
    - `assertions`
      - A description of the assertions executed in the test. By default, only failing assertions will be listed.

MIME type: text/xml

To receieve a `text/xml` response, the optional `JUnitFormat` variable in the request body must be set to `true`. JUnit responses can be useful when you wish to incorporate your test reults with a build pipline such as Jenkins, via the JUnit plugin.

```
<?xml version="1.0" encoding="UTF-8"?>
<testSuite name="" tests="" disabled="" errors="" failures="" timestamp="" time="">
<testcase name="" classname="" time="">
  <failure message="" type="" />
</testcase>
</testSuite>
```

Response Description

- `<testSuite>`
  - Child Elements: `<testCase>`
  - Attributes:
    - `name`
      - Test Suite name.
    - `tests`
      - Number of published tests ran.
    - `disabled`
      - Number of disabled tests.
    - `errors`
      - Number of errors.
    - `failures`
      - Number of tests within the test suite that failed.
    - `timestamp`
      - Date and time the tests were ran.
    - `time`
      - Total duration of all test runs in seconds.
- `<testCase>`
  - Child Elements: `<failure>`
  - Attributes:
    - `name`
      - Test name.
    - `classname`
      - ID of the test which was executed.
    - `time`
      - Total duration of the test run in seconds.
- `<failure>`
  - Attributes:
    - `message`

	▪ Failure message containing the expected and actual response. ▪ `type` ▪ Type of failure.
Status Codes	200: Success 400: Missing Authorization Headers 401: Invalid Authorization Headers

Run Published Tests By Tag

Description

The Run Published Test By Tag endpoint executes all of the published tests within an API Hook's scope that match the tags specified in the request body. See Tagging a Test for more information on how to tag a test.

HTTP Request

```
POST <API-Hook-URL>/tests/run/tag
```

Sample Method Invocation

```
curl -X POST \
-H X-API-Key:{API-Key} \
-H X-API-Secret:{API-Secret} \
-H Content-Type:application/json \
-d '
    {
      "options": {
          "allAssertions": boolean,
          "JUnitFormat": boolean
      },
      "variables": {
          string: string,
      },
      "tags": {
        "tagList": array[string],
        "operator": enum['not' or 'and' or 'or']
      }
    }
  ' \
<API-Hook-URL>/tests/run/tag
```

Parameters	**Header Parameters** API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.

Request Body	**MIME type: application/json**
	
	`{`
	`options: {`
	`allAssertions: boolean,`
	`JUnitFormat: boolean`
	`},`
	`variables: {`
	`string: string,`
	`},`
	`tags: {`
	`tagList: array[string],`
	`operator: enum['not' or 'and' or 'or']`
	`}`
	`}`
	
	Body Parameters
	
	• `options` (Only required if providing a child element)
	◦ A wrapper object for the containing options on how what data should be returned in the response, or how the response should be formatted.

- Child Elements:
  - **allAssertions** (Optional)
    - When **false**, only the results of failing assertions in the test are returned. When **true**, all assertions in the test are returned. **allAssertions** is **false** by default.
  - **JUnitFormat** (Optional)
    - When **false**, **application/json** format is returned for the test results. When **true**, **text/xml** JUnit format is used for the test results (see **text/xml** response). **JUnitFormat** is **false** by default.
- **variables** (Optional)
  - The variables section is used to pass a list of named variables and their values into the tests being run. It is only used by tests that have been written to make use of variables, and have values stored alongside them. Declaring the variable name as the object key, and its new value as the key's value (as type string), will overwrite the current value of the variable in the test which shares its name with the object key.
- **tags** (Required)
  - A wrapper object containing both the list of tags and the operator to use on them.
  - Child Elements:
    - **tagList** (Required)
      - The list of tags which correspond to the tests you want to execute or ignore (see **operator** element).
    - **operator** (Required)
      - The operator indicates how to treat the list of tags and can be either one of three values: **not**, **and**, **or**.
        - The **not** operator will omit executing any test within the API Hook's scope that has been tagged with a tag listed in the **tagList**.
        - The **and** operator will include any test within the API Hook's scope that has been tagged with all the tags provided in the **tagList**.
        - The **or** operator will include any test within the API Hook's scope that has been tagged with at least one of the tags provided in the **tagList**.

Response Content

MIME type: application/json

application/json is the default response from the endpoint.

```
[
{
  testRunId: string,
  testId: string,
  testName: string,
  location: string,
  initiated: string,
  duration: integer,
  status: enum['passed' or 'failed'],
  reportUrl: string,
  results: {
    warningsCount: integer,
    failureCount: integer,
    httpFailures: array[object],
    criticalFailures: array[object],
    assertions: array[object]
  }
}
]
```

Response Description

- **testRunID**
  - ID of the test run.
- **testId**
  - ID of the test which was executed.
- **testName**
  - Name of the test.
- **location**
  - Location of the agent which excuted the test.
- **initiated**
  - Date and time when the test was initiated.
- **duration**
  - Total duration of the test run in seconds.
- **status**
  - Overall result of the test.
- **reportUrl**
  - URL to the test run report.
- **results**
  - A wrapper object containing the results of the test run.
  - Child Elements:
    - **warningsCount**
      - Count of the HTTP warnings returned by the test assertions.
    - **failureCount**
      - Count of the HTTP status code responses that are greater than 400.
    - **httpFailures**
      - Description of failures whose HTTP Status response code is greater than or equal to 400.
    - **criticalFailures**
      - Description of failures whose HTTP Status response code is greater than or equal to 500.

- `assertions`
  - A description of the assertions executed in the test. By default, only failing assertions will be listed.

MIME type: text/xml

To receieve a `text/xml` response, the optional `JUnitFormat` variable in the request body must be set to `true`. JUnit responses can be useful when you wish to incorporate your test reults with a build pipline such as Jenkins, via the JUnit plugin.

```
<?xml version="1.0" encoding="UTF-8"?>
<testSuite name="" tests="" disabled="" errors="" failures="" timestamp="" time="">
<testcase name="" classname="" time="">
  <failure message="" type="" />
</testcase>
</testSuite>
```

Response Description

- `<testSuite>`
  - Child Elements: `<testCase>`
  - Attributes:
    - `name`
      - Test Suite name.
    - `tests`
      - Number of published tests ran.
    - `disabled`
      - Number of disabled tests.
    - `errors`
      - Number of errors.
    - `failures`
      - Number of tests within the test suite that failed.
    - `timestamp`
      - Date and time the tests were ran.
    - `time`
      - Total duration of all test runs in seconds.
- `<testCase>`
  - Child Elements: `<failure>`
  - Attributes:
    - `name`
      - Test name.
    - `classname`
      - ID of the test which was executed.
    - `time`
      - Total duration of the test run in seconds.
- `<failure>`
  - Attributes:
    - `message`
      - Failure message containing the expected and actual response.
    - `type`
      - Type of failure.

Status Codes	200: Success 400: Missing Authorization Headers 401: Invalid Authorization Headers

Run Published Test By ID

Description

The Run Published Test By ID endpoint executes a single specified test within an API Hook's scope.

HTTP Request

```
POST <API-Hook-URL>/tests/{Test-ID}/run
```

Sample Method Invocation

```
curl -X POST \
-H X-API-Key:{API-Key} \
-H X-API-Secret:{API-Secret} \
-H Content-Type:application/json \
-d '
    {
      "options": {
          "allAssertions": boolean,
          "JUnitFormat": boolean
      },
      "variables": {
          string: string,
      }
    }
  ' \
<API-Hook-URL>/tests/{Test-ID}/run
```

Parameters	**Path Parameters** Test-ID: The ID of the Test to execute. **Header Parameters** API-Key: A valid API Key for the Test Organization this API Hook belongs to. API-Secret: A valid API Secret for the Test Organization this API Hook belongs to.
Request Body	**MIME type: application/json** `{ options: { allAssertions: boolean, JUnitFormat: boolean }, variables: { string: string, } }` **Body Parameters** • `options` (Only required if providing a child element) ◦ A wrapper object for the containing options on how what data should be returned in the response, or how the response should be formatted. ◦ Child Elements: ▪ `allAssertions` (Optional) ▪ When `false`, only the results of failing assertions in the test are returned. When `true`, all assertions in the test are returned. `allAssertions` is `false` by default. ▪ `JUnitFormat` (Optional) ▪ When `false`, `application/json` format is returned for the test results. When `true`, `text/xml` JUnit format is used for the test results (see `text/xml` response). `JUnitFormat` is `false` by default. • `variables` (Optional) ◦ The variables section is used to pass a list of named variables and their values into the tests being run. It is only used by tests that have been written to make use of variables, and have values stored alongside them. Declaring the variable name as the object key, and its new value as the key's value (as type string), will overwrite the current value of the variable in the test which shares its name with the object key.
Response Content	**MIME type: application/json** `application/json` is the default response from the endpoint. `[{ testRunId: string, testId: string, testName: string, location: string, initiated: string, duration: integer, status: enum['passed' or 'failed'], reportUrl: string, results: { warningsCount: integer, failureCount: integer, httpFailures: array[object], criticalFailures: array[object], assertions: array[object] }`

```
    }
    ]
```

Response Description

- `testRunID`
  - ID of the test run.
- `testId`
  - ID of the test which was executed.
- `testName`
  - Name of the test.
- `location`
  - Location of the agent which excuted the test.
- `initiated`
  - Date and time when the test was initiated.
- `duration`
  - Total duration of the test run in seconds.
- `status`
  - Overall result of the test.
- `reportUrl`
  - URL to the test run report.
- `results`
  - A wrapper object containing the results of the test run.
  - Child Elements:
    - `warningsCount`
      - Count of the HTTP warnings returned by the test assertions.
    - `failureCount`
      - Count of the HTTP status code responses that are greater than 400.
    - `httpFailures`
      - Description of failures whose HTTP Status response code is greater than or equal to 400.
    - `criticalFailures`
      - Description of failures whose HTTP Status response code is greater than or equal to 500.
    - `assertions`
      - A description of the assertions executed in the test. By default, only failing assertions will be listed.

MIME type: text/xml

To receieve a `text/xml` response, the optional `JUnitFormat` variable in the request body must be set to `true`. JUnit responses can be useful when you wish to incorporate your test reults with a build pipline such as Jenkins, via the JUnit plugin.

```
    <?xml version="1.0" encoding="UTF-8"?>
    <testSuite name="" tests="" disabled="" errors="" failures="" timestamp="" time="">
    <testcase name="" classname="" time="">
      <failure message="" type="" />
    </testcase>
    </testSuite>
```

Response Description

- `<testSuite>`
  - Child Elements: `<testCase>`
  - Attributes:
    - `name`
      - Test Suite name.
    - `tests`
      - Number of published tests ran.
    - `disabled`
      - Number of disabled tests.
    - `errors`
      - Number of errors.
    - `failures`
      - Number of tests within the test suite that failed.
    - `timestamp`
      - Date and time the tests were ran.
    - `time`
      - Total duration of all test runs in seconds.
- `<testCase>`
  - Child Elements: `<failure>`
  - Attributes:
    - `name`

	▪ Test name. ▪ `classname` ▪ ID of the test which was executed. ▪ `time` ▪ Total duration of the test run in seconds. • `<failure>` ○ Attributes: ▪ `message` ▪ Failure message containing the expected and actual response. ▪ `type` ▪ Type of failure.
Status Codes	200: Success 400: Missing Authorization Headers 401: Invalid Authorization Headers

Test definition syntax

The test is defined as a YAML file with the following sections:

```
 requirements: {}

info:
  title: "New Configuration YAML File"
  version: 2

configs:
  globalVariables:
    protocol: https://
    domain: sample-api.us-east-a.apiconnect.automation.ibm.com
    basePath: /bank

  inputs:
    - default:
        value: string
        type: array
    - second:
        value: number
        type: string

  steps:
    - type: request
      method: get
      url: "{{ configs.globalVariables.protocol }}{{ domain }}{{ globalVariables.basePath }}/branches"
      var: branches
      mode: json

    - type: assert-is
      expression: branches
      value: "{{ type }}"

    - type: assert-exists
      expression: branches.[1]
      stoponfail: true

    - type: assert-is
      expression: branches.[0].type
      value: string
      stoponfail: true

    - type: assert-is
      expression: branches.[0].address.city
      value: string
      stoponfail: true

    - type: assert-compares
      expression1: branches.[0].type
      expression2: branches.[7].type

    - type: request
      method: get
      url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/orders/order/AB1234
      var: payload
      mode: json

    - type: assert-equals
      expression: payload_response_statusCode
      value: 200
      ifexists: false
      stoponfail: false

    - type: assert-equals
      expression: payload_response_header_Content-Type
      value: application/json

    - type: assert-in
      expression: payload_response_header_Content-Type
      values:
        - application/json
```

```
      - application/swagger+yaml

  - type: assert-contains
    expression: payload_response_header_Content-Type
    value: app

  - type: assert-matches
    expression: payload_response_header_Content-Type
    value: ^[a-z]+/json

  - type: assert-exists
    expression: "payload"
    stoponfail: false

  - type: assert-is
    expression: "payload.tracking_reference"
    value: "string"
    ifexists: "false"
    stoponfail: false

  - type: assert-exists
    expression: payload.shipped_at
    stoponfail: false

  - type: assert-exists
    expression: payload.status
    stoponfail: false

  - type: assert-exists
    expression: payload.created_at
    stoponfail: false
```

Table 1. Summary of the parameters supported by the type attribute

Parameters	Description	Sub-attributes
globalVariables	Global variables are settings that remain consistent across the entire test and typically do not change between runs.	You can define any attributes here based on your requirements. For example: - portocol: Specifies the protocol (for example, `https://`) used in all requests, ensuring secure communication. - domain: Specifies the primary server address for API requests. - basepath: Defines the base path for all API endpoints (for example, `/bank`), which is appended to the domain for constructing request URLs.
inputs	Defines various sets of input parameters used across multiple test scenarios.	You can create multiple data sets with any attributes needed for specific test scenarios. For example, default and second are two data sets, each with its own attributes tailored for different scenarios. Note: At least one data set must be present to run the test.
request	Make an HTTP request.	- method: Defines the HTTP method to use. - url: Defines the URL to make the request to. - params: Defines the key value mapping of parameters to send. - headers: Defines the key value mapping of headers to send. - var: Defines the name of the variable to store the response in. - mode: Defines what type of data to expect and how to parse it (supported: json). For example: - type: request - method: get - url: https://sample-api.us-east-a.apiconnect.automation.ibm.com/bank/branches - var: branches - mode: json
assert-is	Assert that the type of variable from the response is value.	- expression: Defines the variable to test. - value: Defines the type we expect in response. For example: - type: assert-is expression: branches value: array
assert-exists	Assert that a particular variable specified in expression exists.	- expression: Defines the variable to test. - stoponfail: If one of the tests fails, the stoponfail attribute stops the execution of the remaining tests. For this, stoponfail must be set to true. For example: - type: assert-exists expression: branches.[1] stoponfail: true
assert-equals	Assert that a variable is equal to value.	- expression: Defines the variable to test. - value: Defines the value to compare against. For example: - type: assert-equals expression: payload_response_header_Content-Type value: application/json

Parameters	Description	Sub-attributes
assert-greater	Assert that the variable is greater than value.	- expression: Defines the variable to test. - value: Defines the value to compare against. For example: - type: assert-greater expression: payload_temperature value: application/json
assert-less	Assert that the variable is lesser than value.	- expression: Defines the variable to test. - value: Defines the value to compare against. For example: - type: assert-less expression: payload_temperature value: application/json
assert-in	Assert that the element identified by a given expression matches at least one item from a given list.	- expression: Defines the variable to test. - value: Defines an array of values to compare against. For example: - type: assert-in expression: payload_response_status value: application/json
assert-matches	Assert that the value of the element identified by a given expression matches a specified format.	- expression: Defines the variable to test. - value: Defines the regex value to compare against. For example: - type: assert-matches expression: payload_response_header_Content-Type value: [1]+/json
assert-compares	Assert that two elements are equivalent in some way.	- expression1: Defines the path to the first element for comparison. - expression2: Defines the path to the second element for comparison. For example: - type: assert-compares expression1: branches.[0].type expression2: branches.[7].type
assert-contains	Assert that the value of the element identified by a given expression contains a specific substring.	- expression: Defines the variable to test. - value: Defines the substring to compare against. For example: - type: assert-contains expression: payload_response_header_Content-Type value: app
each	Loop over the array referenced in the expression carrying out the sub-steps for each item found.	- expression: Defines the variable to test. For example: - type: each expression: "analytics.events"

if	If the specified condition (defined in the expression) is met, the assertions in the if-condition steps will be executed; otherwise, they will be skipped.	- expression: condition to test
		- steps: sub-steps that ATM executes if the condition succeeds
		For example,
		`- type: if`
		`expression: "{{payload_response_statusCode}} == 200"`
		`steps:`
		`- type: assert-is`
		`expression: "payload.tracking_reference"`
		`value: "string"`
		`stoponfail: false`

Tutorial: Invoking test cases from Jenkins with JUnit result format

Before you begin

You must have the Automated API behavior testing application enabled and have created and published at least one test. You must have a Jenkins instance that you can create a new build in with the JUnit Plugin installed

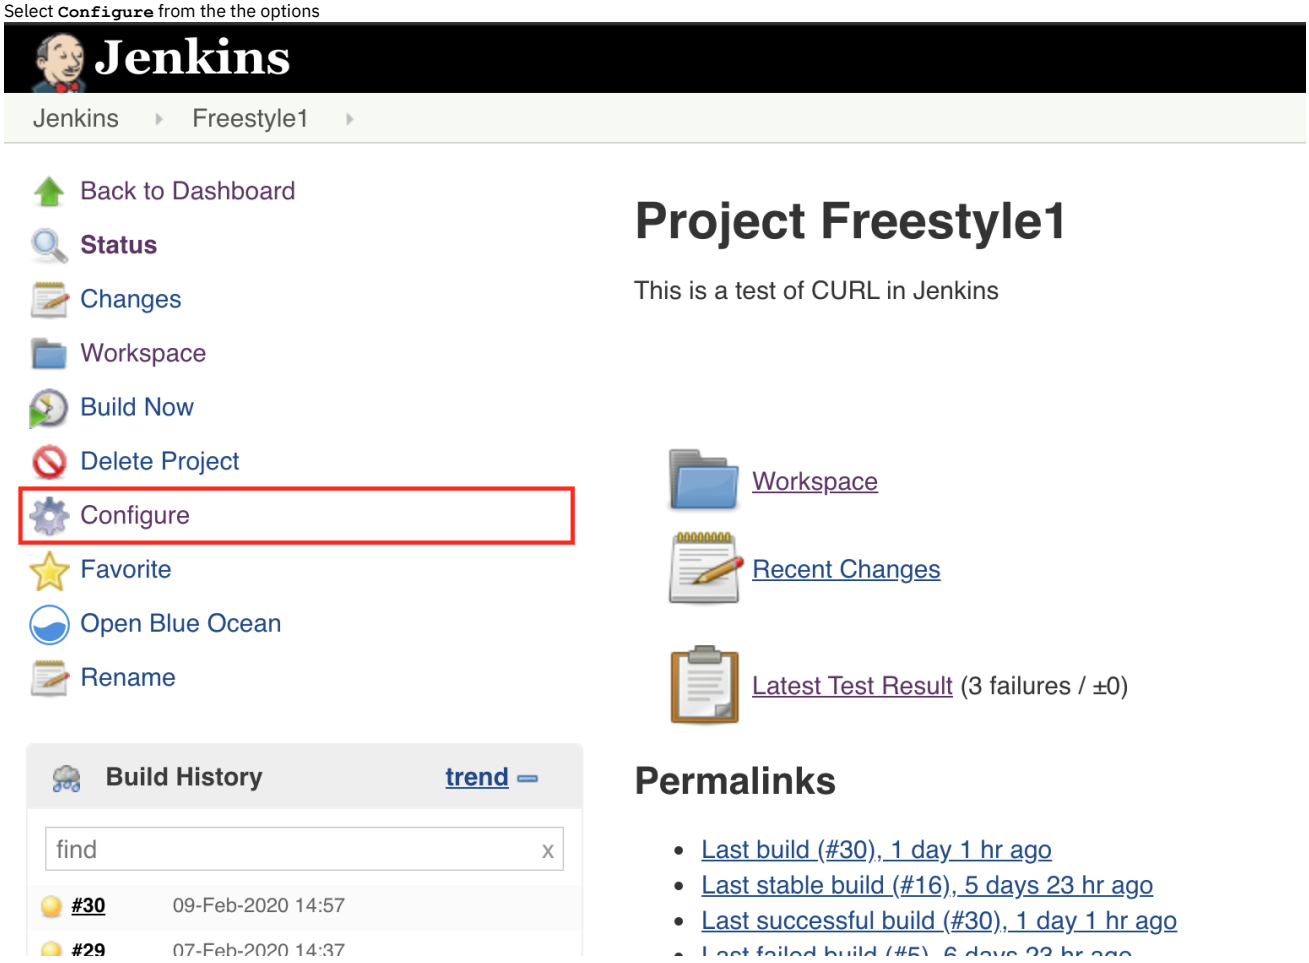
About this tutorial

In this tutorial, you invoke a test case using injected variables from a jenkins pipeline

This tutorial takes you through the following steps

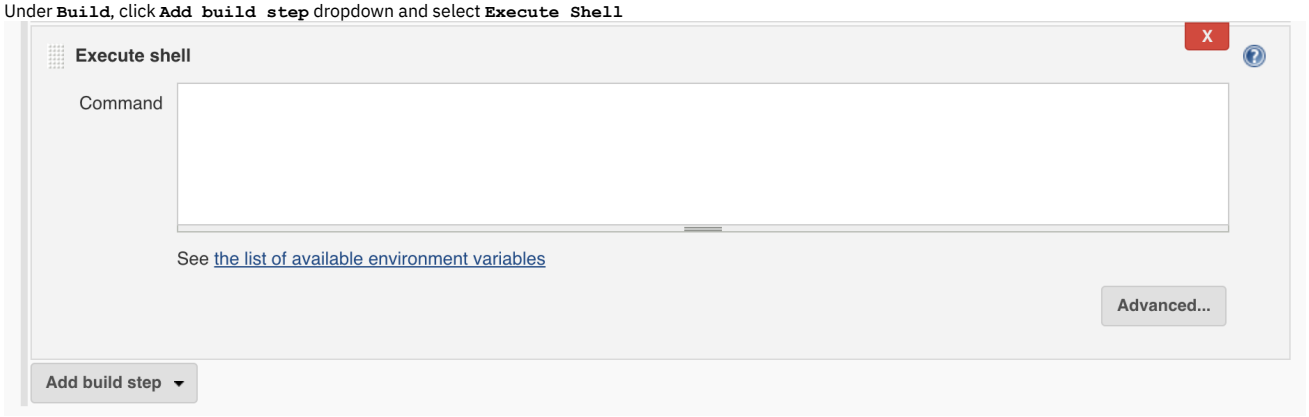
1. Creating an API Hook
2. Creating an API Key and Secret
3. Creating a Jenkins build that invokes the API Hook
4. Executing the build and reviewing the test results

Creating an API Hook



See Creating an API Hook

Creating an API Key and Secret

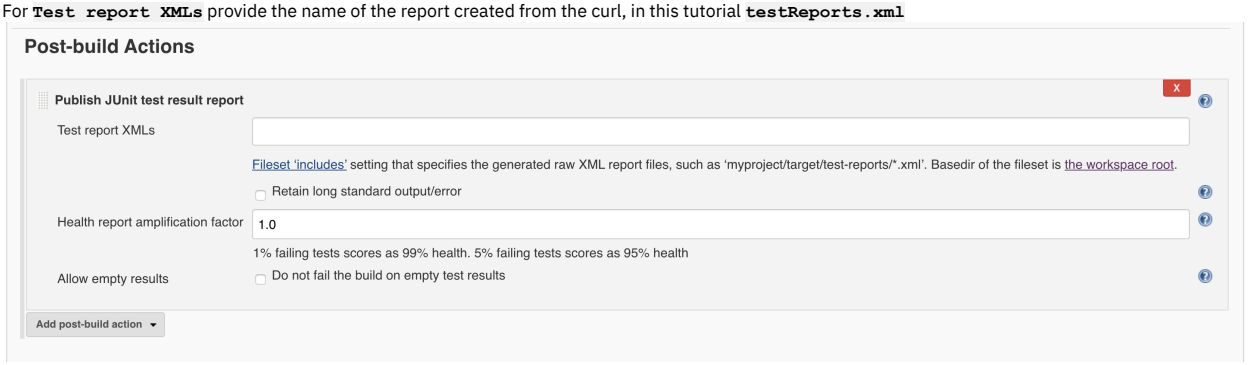


See Creating an API Key and Secret

Creating a Jenkins build that invokes the API Hook

1. Create a Jenkins Project or navigate to an existing one
2. Select **`Configure`** from the the options

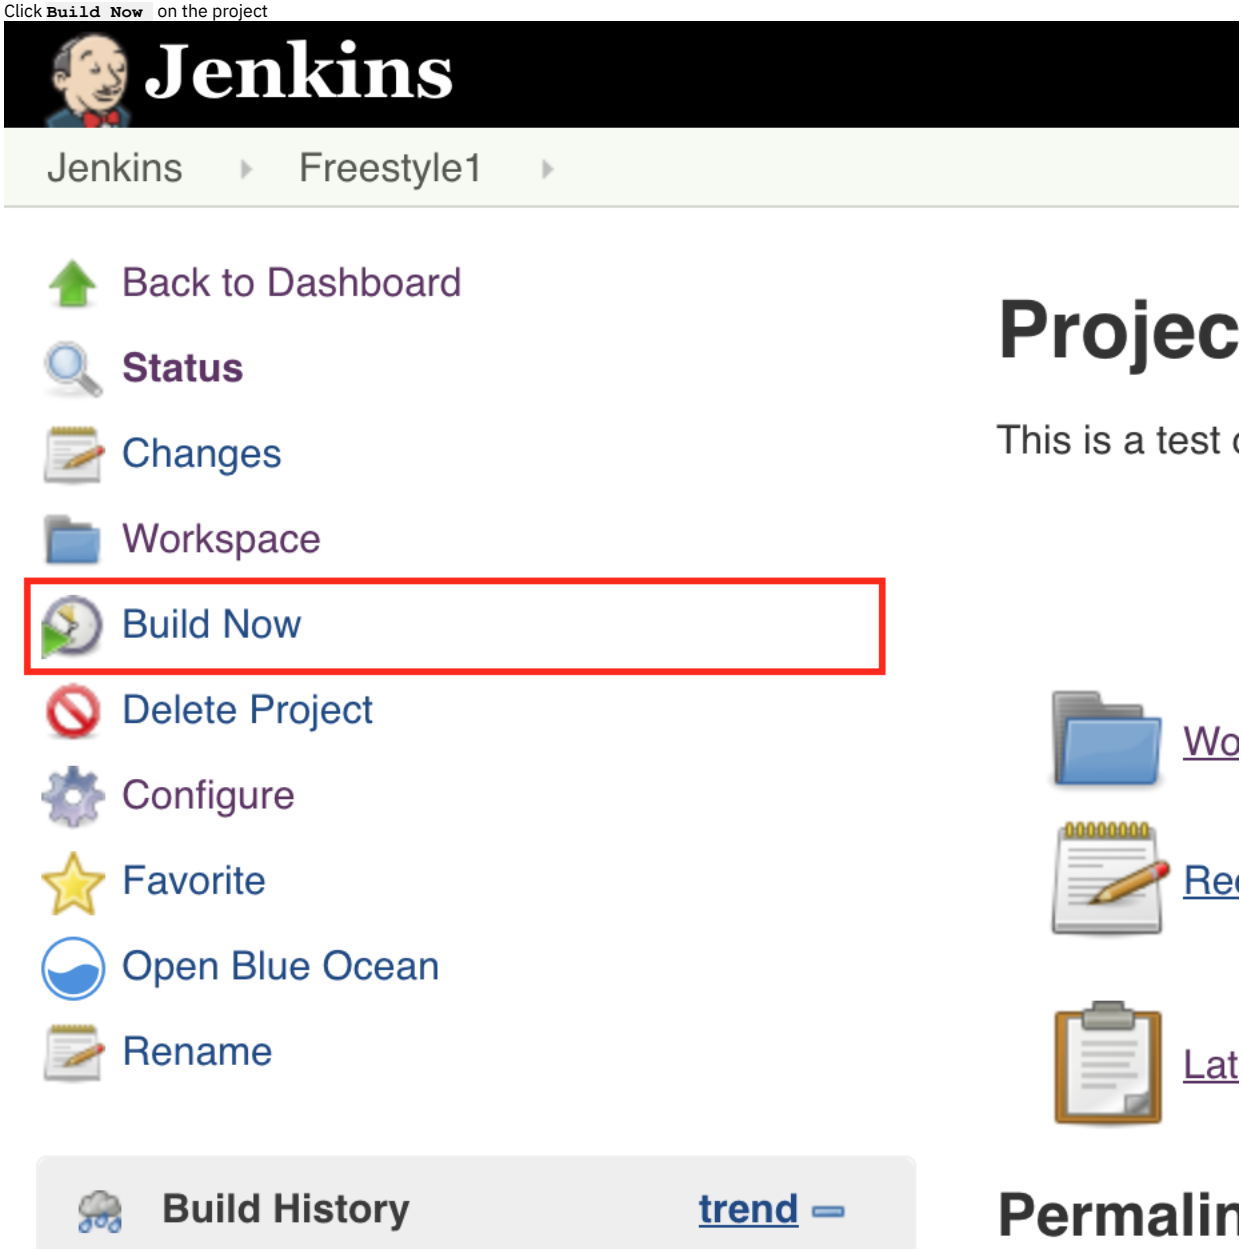
3. Under **`Build`**, click **`Add build step`** dropdown and select **`Execute Shell`**



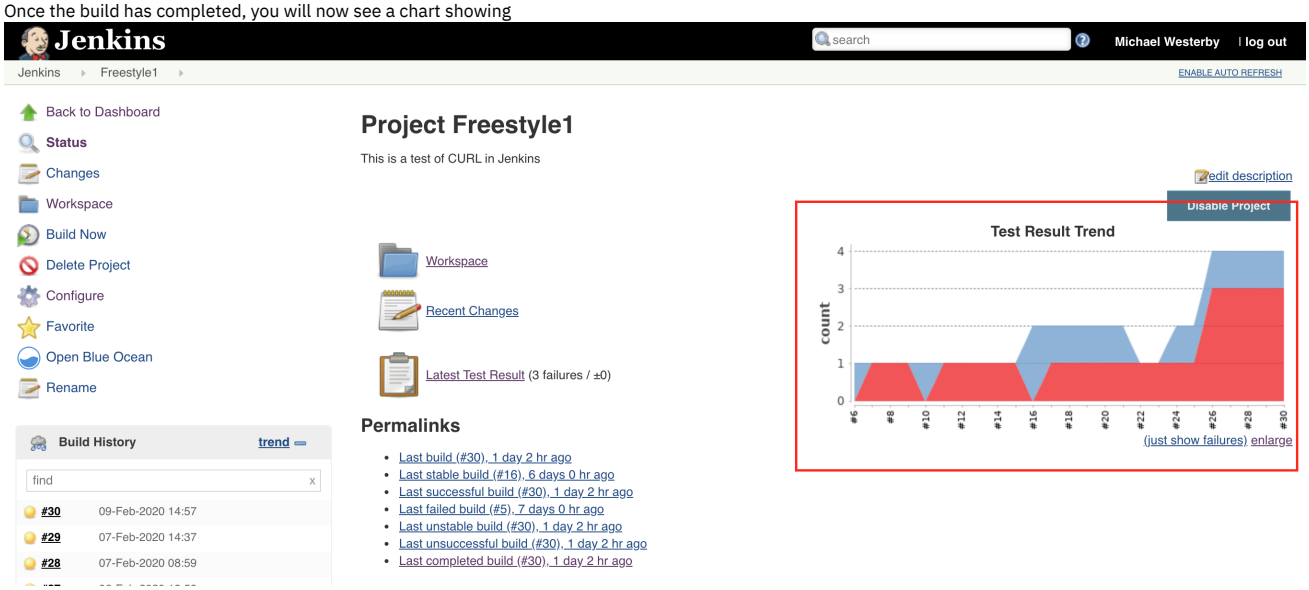
4. Within the **`Execute shell`** block paste a **`curl`** command that will invoke the hook that was created in step 1

```
curl -XPOST
-H 'x-api-key: <API-KEY>'
-H 'x-api-secret: <API-SECRET>'
-H "Content-type: application/json"
```

```
-d '{ options: { JUnitFormat: true }}'
'<API-HOOK-URL>/tests/run'
>| testReports.xml
```

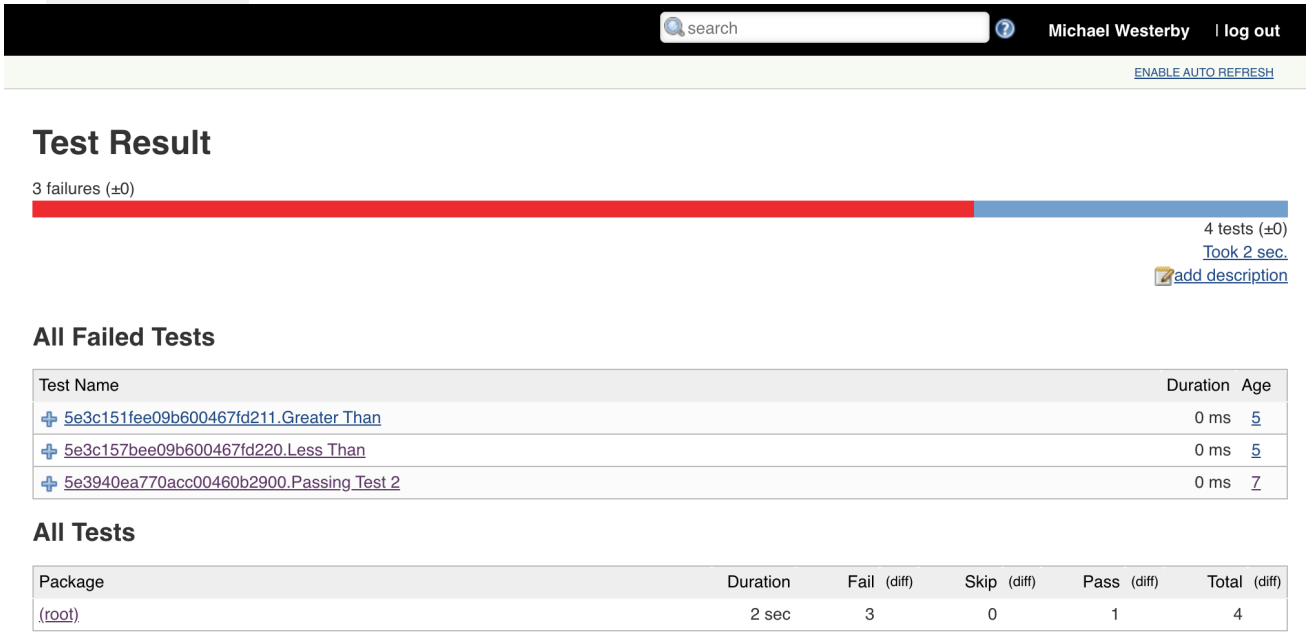


5. Under **Post-build Actions**, click **Add post-build action** and in the dropdown select **Publish JUnit test results report**.
    1. For **Test report XMLs** provide the name of the report created from the curl, in this tutorial **testReports.xml**



6. Save the project

Executing the build and reviewing the test results



1. Click **Build Now** on the project

2. Once the build has completed, you will now see a chart showing

3. Click **`Latest Test results`** and review the Junit results

To expand upon this tutorial additional options and steps can be found under Using API Hooks

What you did in this tutorial

In this tutorial you completed the following activities:

- Created a API Hook
- Created a Key and Secret used for authenicating with a hook
- Invoked the API Hook using the Key and Secret to start a test and process the results

AutoTest Assist

The AutoTest assistant exercises your API by sending it a series of randomly-generated requests, guided by the API definition and any custom rules that you provide, and alerts you about any conformance errors and server-side errors that it observes.

You control the auto-tester by creating and running an AutoTest *profile,* and you can create multiple profiles against the same API to cover different use-cases. A profile specifies how the auto-tester should run, which endpoints it should test, and what kind of data it should send. A default profile is constructed so that you can get immediate feedback by providing no more than a target URL and credentials.

The AutoTest assistant is especially useful while an API is under development as it can quickly identify errors in an implementation without you having to write test cases. It is also valuable later in the cycle for spotting regressions, as the random nature of its requests can provide coverage that your existing test cases do not match. However, it is not meant as a replacement for other testing tools in API Connect, but is rather complementary, and the information it provides when it identifies an error is often a good starting point for creating a test case.

Follow these steps to create and run your first profile:

- Creating a profile
- Modifying a profile
- Deleting a profile
- Running a profile
- Viewing the report

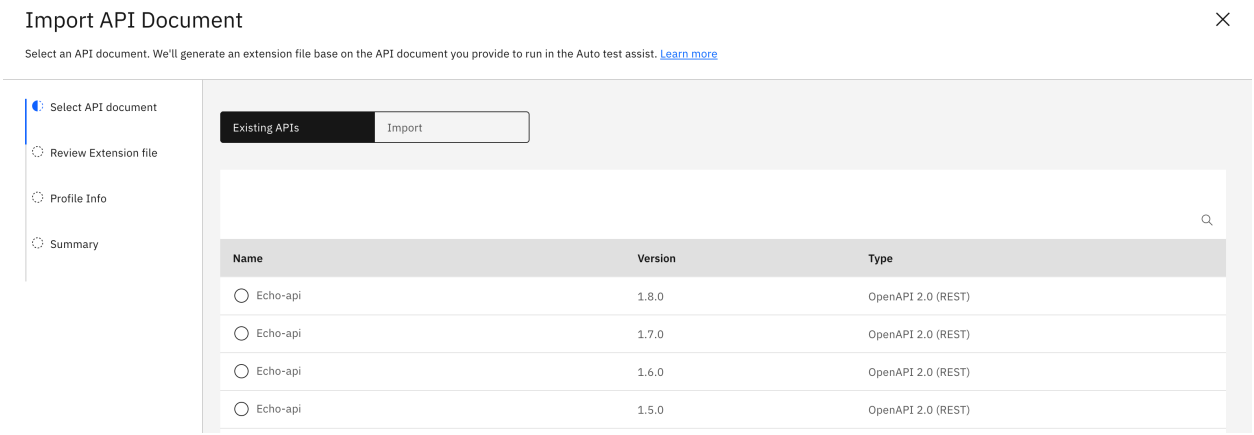
Consult these additional guides for detailed instructions on how to configure the auto-tester to support your use case:

- Profile Configuration
- Profile Security
- Data Generation Rules

Known limitations

- The API definition must conform to OpenAPI 2.0 (Swagger 2.0)
- The API definition document must have a `.json` or `.yaml` extension (you cannot select a document with another extension)
- If there are errors in the API definition then you will see only a blank screen, and the errors are not reported
- You must provide either a username and password, or a bearer token, to authenticate against the target API; other authentication methods are not supported
- You can run only one profile at a time

Creating an AutoTest profile



An AutoTest profile exists within a test suite, alongside your test cases.

To add an AutoTest profile to a test suite:

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. Go to the **Tests** > **AutoTest Profiles** tab.
5. Click **Add**.
6. Create an AutoTest profile using one of the following methods:

Existing APIs

1. Select a predefined API.

2. Click **Next**.
3. Review the read-only extension file.
4. Enter the profile name, description, and tags.
5. Click **Next**. You will see the message that the extension file and the AutoTest configuration has been generated.

Import

1. Drag and drop a JSON or YAML file that contains the API test case definition, or enter a URL for the API test case and provide a username and password if required for authentication.
2. Click **Next**.
3. Review the extension file and click **Next**.
4. Enter the profile name, description, and tags.
5. Click **Next**. You will see the message that the extension file and the AutoTest configuration has been generated.

What to do next

- Next topic: Running an AutoTest profile

Modifying an AutoTest profile

To edit an AutoTest profile in a test suite:

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. Go to the **Tests** > **AutoTest Profiles** tab.
5. Select an AutoTest profile.
6. Go to the **Info** tab, update the profile name, description, and tags, then click **Save**.
7. To edit the extension file, click the extension file, update the settings, and click **Save**. For more information, see API Extensions

What to do next

- Next topic: Running an AutoTest profile

API Extensions

An **API Extension** augments an OpenAPI definition with semantic information designed to improve the automatic generation of test cases. Extensions are used primarily by the AutoTest assistant to refine its randomly-generated test cases, but have wider applicability.

An extension comes in two parts:

- Resources identify the key resource types managed by the API, and their methods
- Properties attach semantic categories to schema properties, to constrain the format of values suggested for those fields

An extension is associated with a specific OpenAPI document and uses JSON Pointer notation to locate terms in that document.

Resources

The `resources` section contains a set of resource definitions, where each definition contains at least the following:

- a name for the resource
- a pointer to a schema of type `object` that models the resource
- a collection of methods that operate on the resource

Typically, a resource definition also identifies a field within the schema that stores a unique identifier for instances of that type.

For example, consider this extract from an API extension:

```
resources:
  Book:
    schemas:
      primary:
        json_ptr: '#/definitions/Book'
    properties:
      id_name: '$.book_id'
    operations:
      create:
        - json_ptr: '#/paths/~1books/post'
      retrieve:
        - json_ptr: '#/paths/~1books~1{book_id}/get'
        - json_ptr: '#/paths/~1books/get'
      update:
        - json_ptr: '#/paths/~1books~1{book_id}/put'
      delete:
        - json_ptr: '#/paths/~1books~1{book_id}/delete'
```

The `resources` section contains a single resource definition with the following properties:

- it defines a resource named `Book`
- a book is modeled by a schema of the same name located in the OpenAPI document under `definitions`
- each book has a property `book_id` that holds its unique ID
- there are operations defined in the OpenAPI document under `paths` that create, retrieve, update and delete books

The correspondence between the resource name and the schema name is common but not required: a resource name can be anything, as long as it is unique within the API.

The unique ID field for a book is identified by a simplified form of JSON Path expression that locates a property (`book_id`) within the primary schema.

Operations (or methods) on a resource are grouped by category:

- Create
- Retrieve
- Update

- Delete

There can be multiple operations in each. In this example there are two operations that retrieve books: one that returns a single book by ID, and another that returns a list of books, and this is common. A different definition might have **patch** as well as (or instead of) **put** under **update**.

JSON Pointer expressions in a resource definition all refer implicitly to the associated OpenAPI document, so the prefix **#** introduces a relative location within that document. JSON Pointer syntax uses the string **~1** to stand for a forward slash character (**/**) to prevent confusion with the same character used as a separator, so the operation defined in the OpenAPI document by the term:

```
paths:
  /books/{book_id}:
    get:
```

is identified here by the JSON Pointer:

```
#/paths/~1books~1{book_id}/get
```

Dependencies

A resource definition may also describe a dependency from one resource type to another.

For example:

```
  Order:
    schemas:
      primary:
        json_ptr: '#/definitions/Order'
    properties:
      id_name: '$.order_id'
    dependencies:
      - name: Book
        required: true
        references:
          - name: $.book_id
            in: body
        dependee_deletion: disabled
      - name: Customer
        required: true
        references:
          - name: customer_id
            in: path
        dependee_deletion: mutual
    operations:
      create:
        - json_ptr: '#/paths/~1customers~1{customer_id}~1orders~1{order_id}/post'
      # rest omitted for brevity
```

This definition says that the resource **Order** has dependencies on two other resources **Customer** and **Book** (which must be defined in the same extension).

Both dependencies are **required** in the sense that an order cannot exist unless there is a customer (to place the order) and at least one book (to buy).

An order refers to an existing book through the property **book_id** in the primary schema, and to a customer through the path parameter **customer_id**, as in the **create** method shown (and in other methods omitted).

A customer *owns* a set of orders; this is a hierarchical relationship implicit in the path:

```
/customer/{customer_id}/orders/{order_id}
```

When a customer is deleted, all their orders are also deleted, and this behavior is indicated by the **mutual** value of the deletion property.

A different relationship applies to books: a book cannot be deleted until all the orders which refer to it have been deleted, so deletion is indicated as **disabled** in that case.

There are three possible values for the **dependee_deletion** property:

- **enabled**: a referenced resource can be deleted even while dependent resources that refer to it still exist
- **disabled**: a referenced resource cannot be deleted until all dependent resources that refer to it have been deleted
- **mutual**: deleting a referenced resource deletes all the dependent resources that refer to it: this is typical where the dependent is owned by or contained in the referent

Pure resources

A pure resource is one that has no instances, or at least no instances that can be tracked with unique IDs, and is used as a placeholder for operations that do not behave as resource methods.

A pure resource differs from a standard resource in the following ways:

- it has no ID field (because there are no instances)
- dependencies have no **dependee_deletion** (for the same reason)
- all operations are grouped under a single **pure** category

For example:

```
ServiceAvailability:
  schemas:
    primary:
      json_ptr: '#/definitions/ServiceAvailability'
    operations:
      pure:
        - json_ptr: '#/paths/~1service~1status/get'
```

ServiceAvailability is a type that is returned as the result of a service status request but has no unique, persistent state.

Properties

The **properties** section assigns semantic categories to schema properties occurring in operation payloads, to constrain the range of values interpolated into generated request bodies.

For example:

```
properties:
  - json_ptr: '#/definitions/CardPayment'
    items:
      - name: card_number
        semantic: credit_card_number
      - name: expiry_date
        semantic: expiry
      - name: security_code
        semantic: cvv
```

The JSON Pointer expression locates a schema named **CardPayment** in the API document under **definitions**; the schema must have **object** type with at least the properties **card_number**, **expiry_date** and **security_code** which are specified here to have particular semantics that will guide the auto-generation of appropriate values wherever a **CardPayment** occurs in a request payload.

Semantic categories must be drawn from the following set:

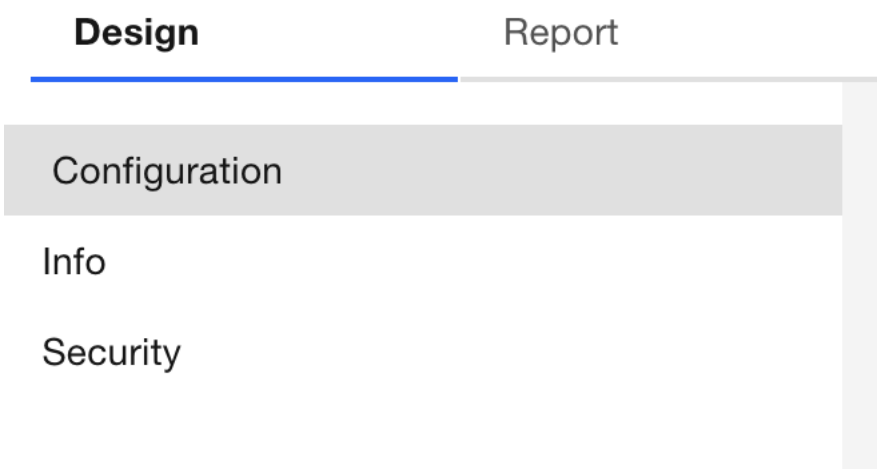
address	cvv	latitude	state_code
age	date	longitude	street
area_code	domain	minutes	temperature
birthday	email	month	time
certificate	expiry	name	timestamp
charset	first_name	number	token
cidr	gender	paragraph	twitter
city	geo_location	percentage	url
color	hours	phone	user_agent
content_encoding	humidity	phone_number	username
content_type	iban	prefix	uuid
coordinates	id	pressure	version
country	identity_provider	price	year
country_code	ip_address	revision	zip_code
credit_card_number	language	sentence	
currency	language_code	social_security_number	
currency_code	last_name	state	

Collection points to a schema that describes a set of resources. It's typically used to retrieve a list of resources.

Deleting an AutoTest profile

To delete an AutoTest profile in a test suite:

1. Log in to the API Manager.
2. Click the **Test APIs** tile.
3. On the Test page, select a test suite.
4. Go to the **Tests** > **AutoTest Profiles** tab.
5. On the **Tests** > **AutoProfiles** tab, locate the AutoTest profile you want to delete, click the **Options** icon > **Delete** option.

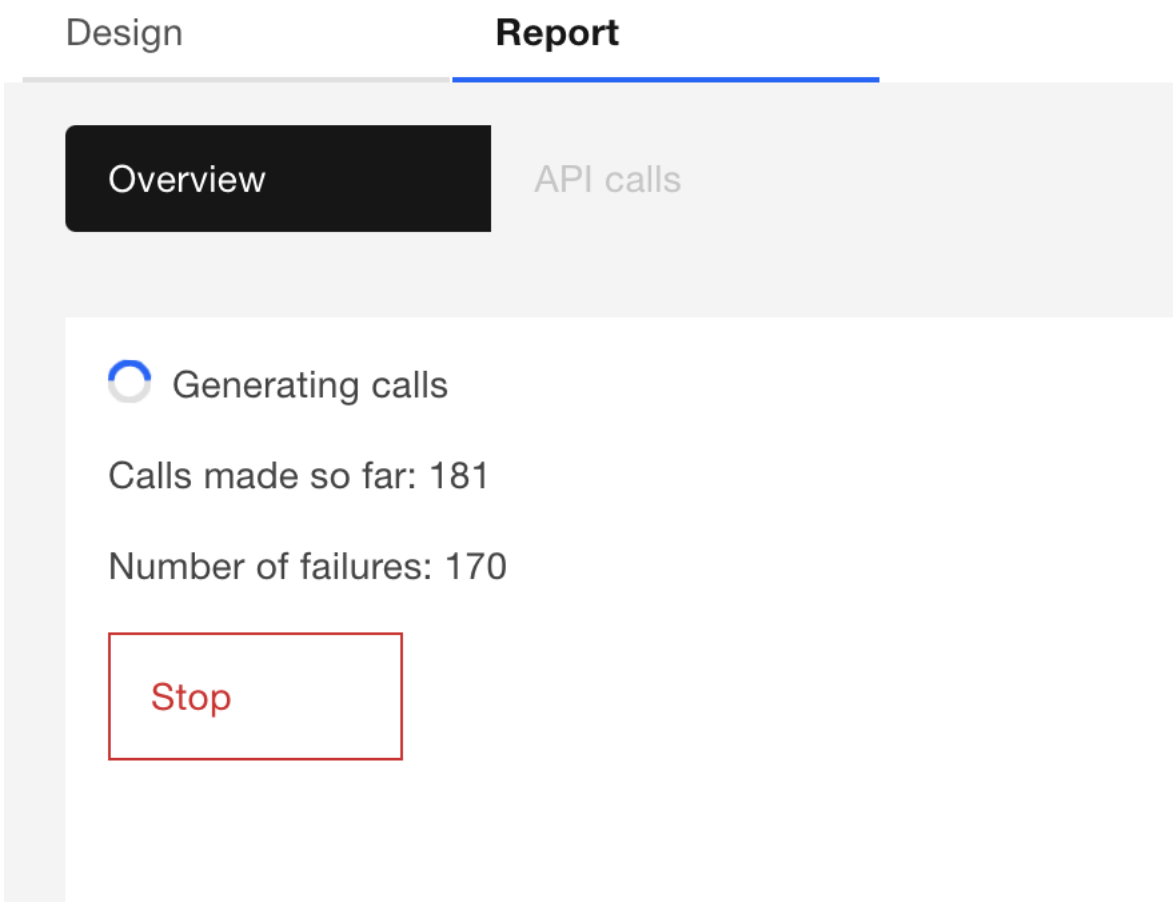


What to do next

- Next topic: Running an AutoTest profile

Running an AutoTest profile

To be able to run an AutoTest profile you will need to configure it first. Make sure to set the ServerURL parameter correctly otherwise all the generated API calls will fail. For more information please refer to AutoTest Profile Configuration. At any point during this process you can click on the save button to maintain your progress.



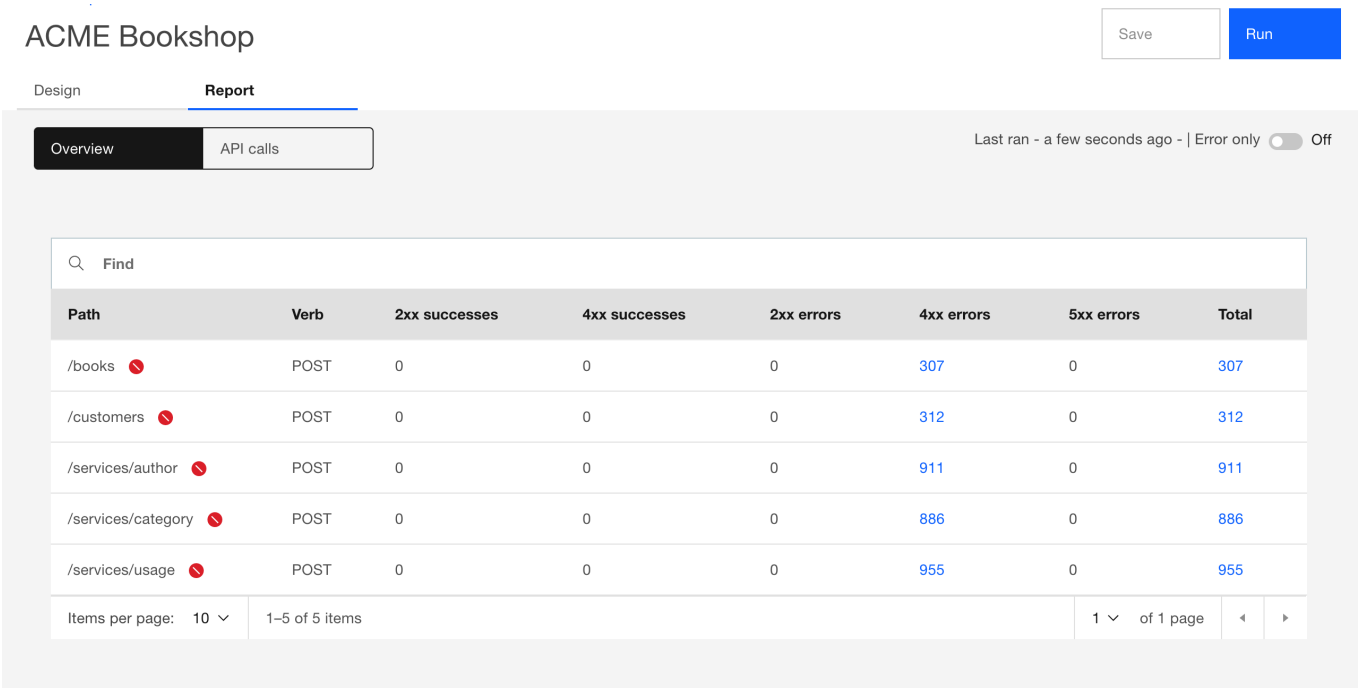
Once you have made your changes in the configuration panel, go to the security panel to set your authentication.

For more information read through AutoTest Profile Security.

Once you have made all your changes to the configuration and security. You can either save, or click on the run button.

This will take you to the report page where the exerciser will generate calls to test the API.

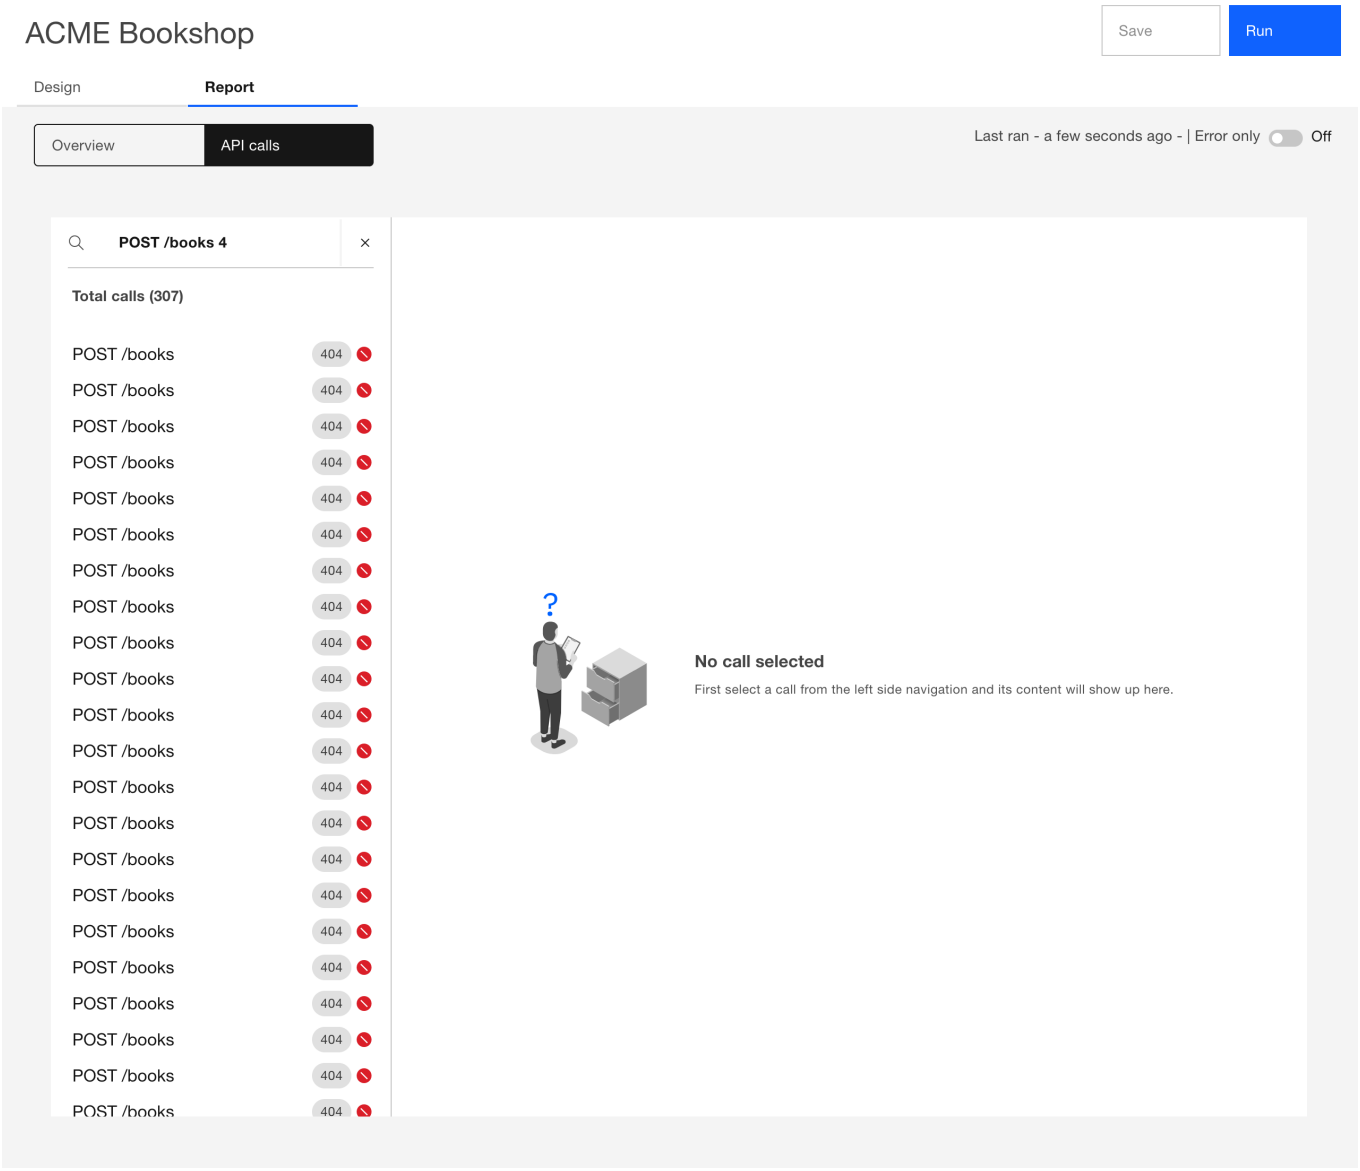
Once the generation has finished, it will take you to the next step AutoTest Report



What to do next

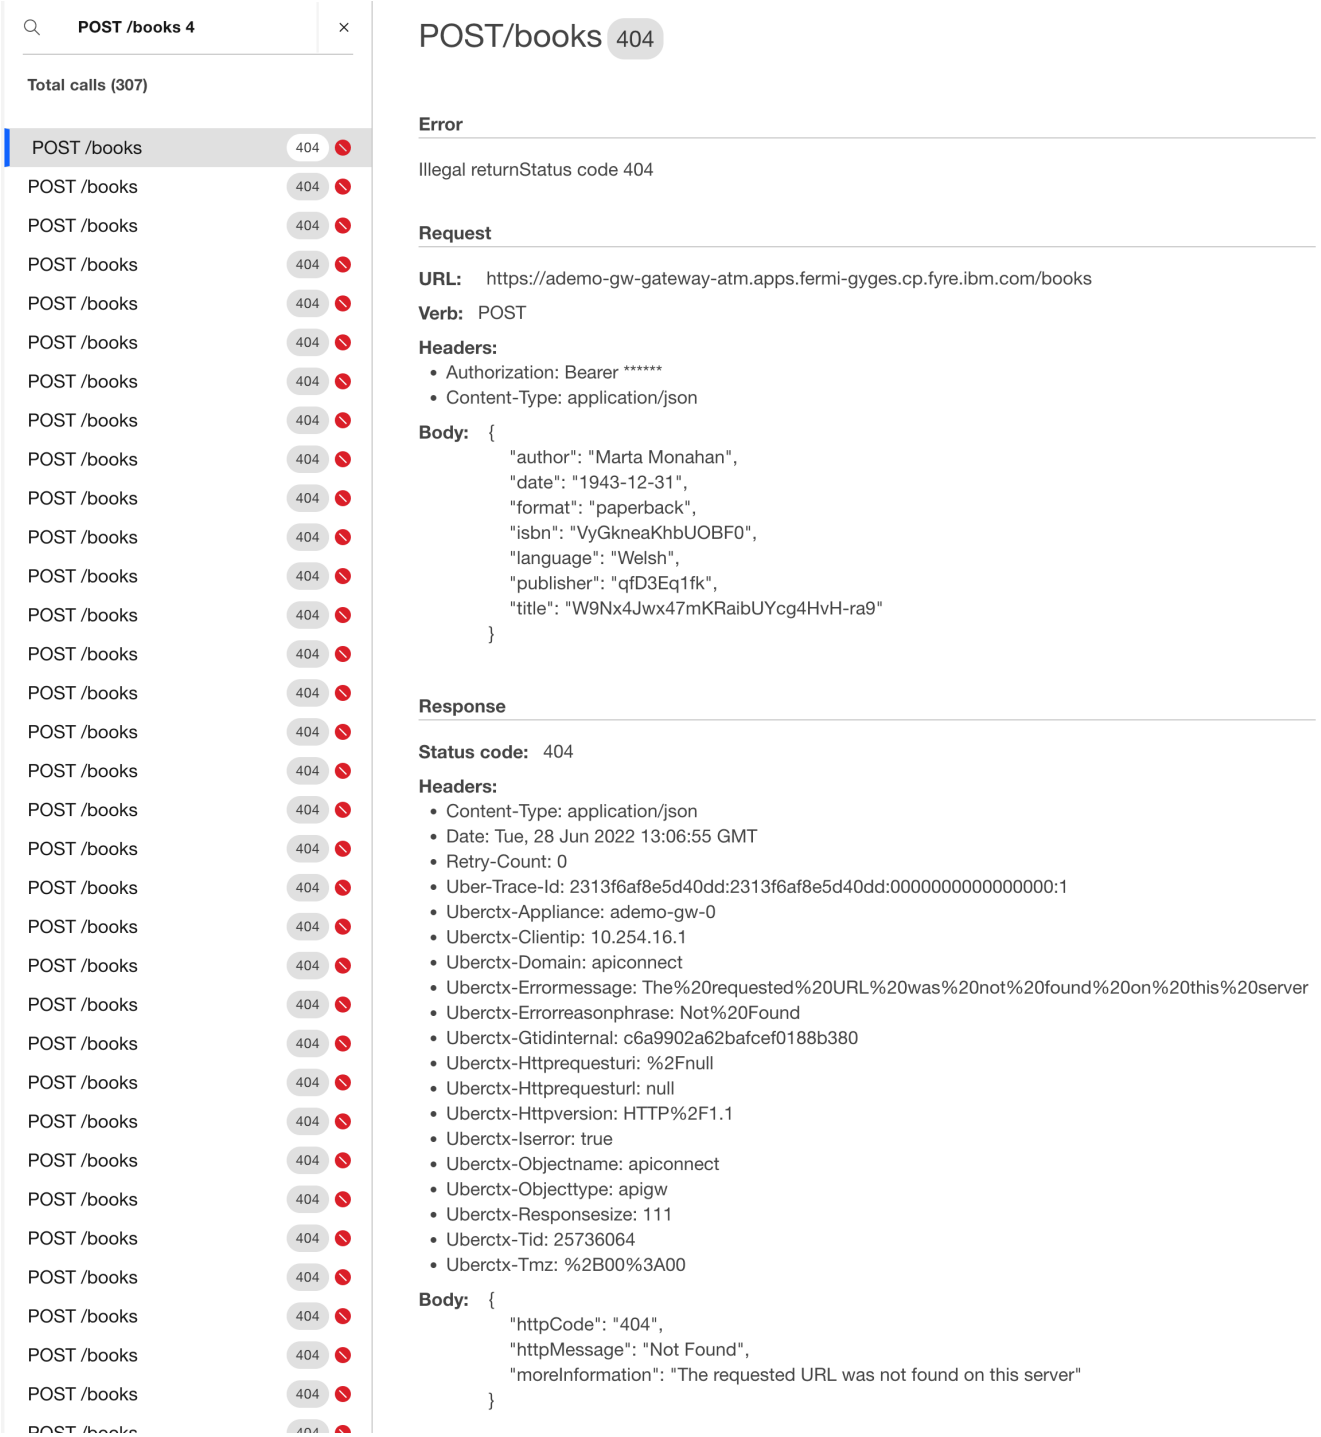
- Next topic: Viewing the AutoTest Report

Viewing the AutoTest report



Once the AutoTest run has completed (either stopped manually or the configured time to run threshold has been reached) you will be presented with the **Report** section, where you will be able to view the results of the run.

First up is the **Overview** tab, which contains a table displaying all the paths defined in the AutoTest profile's API specification, alongside their associated HTTP methods (verbs), and followed by the number of each class of responses received throughout the course of the AutoTest profile run.

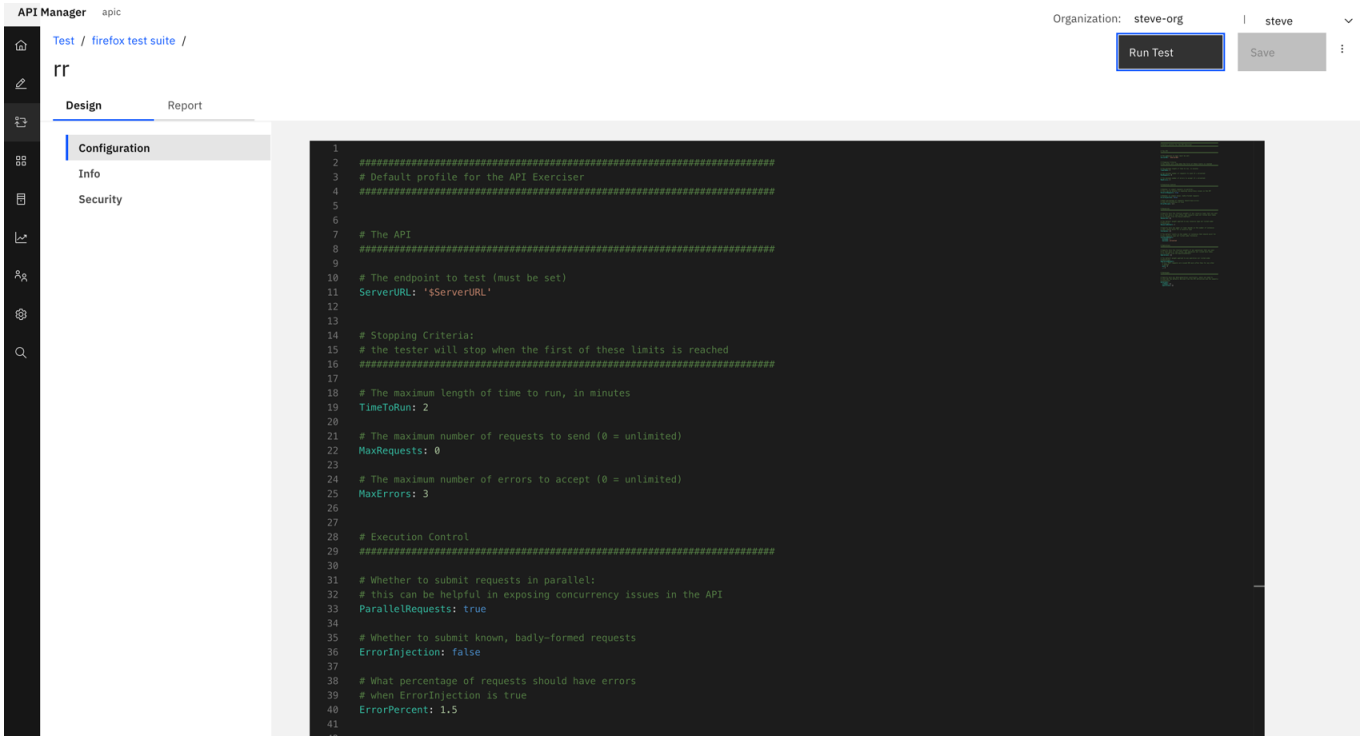


The **API calls** tab contains a more detailed view of every API call made by the run. The left side contains the list of the calls and their respective response statuses; the search bar lets you filter on the HTTP method, the path, and the response code; this should make it relatively easy to find specific requests amongst the potentially large number of API calls.

You can also get to the details view by clicking on any of the non-zero numbers in the overview table; this will automatically filter the list of API calls by the appropriate class of responses (or just the path and verb if the total tally is clicked on), as shown below.

*Either of the two views lets you apply a global **Errors only** filter by interacting with the toggle in the top right corner, under the **Save** and **Run** buttons. This will apply a filter to both the overview table and the detailed API calls list so that they will either display only errored or all requests.*

Selecting one of the calls from the list will render the details of that call on the right hand side. As seen below information such as headers and bodies for both the request and response is shown. This lets you closely exmaine precisely how a specific API endpoint had been called and the response the request received.



Profile Configuration

The configuration controls the execution of your profile; it determines for how long the test should run, and what kinds of requests it should generate. A newly-created profile includes a default configuration that you can run immediately to check that the auto-tester works with your API. The one thing you may have to set or change before you can run is the target Server URL which must point to your test deployment; the default value is copied from the API definition, where one is provided. You must also specify appropriate authentication settings on the separate **`Security`** tab (see Profile Security).

The configuration is in YAML format. The editor highlights syntactic errors as you type, and verifies the content for consistency with the API definition each time you press **`Save`**. If there is an error in the configuration, then the profile cannot run.

The Profile Configuration editor

Sections in the configuration:

- The API
- Stopping Criteria
- Execution Control
- Resources
- Operations
- Datatypes

The API

ServerURL

The server URL is the single endpoint to which all requests are sent. It must be a valid URL, reachable from your namespace, and include at least a scheme and a server address; it may also include a port number and a path prefix. It must not include a trailing slash. The server URL is prefixed to an operation path from the API definition to create the target of a request. For example, given this URL definition from the configuration:

```
ServerURL: https://api-host:8000/apis
```

And this operation path from the API definition:

```
paths:
  /movies:
    post:
```

The auto-tester will send **POST** requests to this target URL:

```
https://api-host:8000/apis/movies
```

Stopping Criteria

The profile stops running as soon as any of these criteria are met.

TimeToRun

The maximum length of time to run, in minutes: the auto-tester stops sending requests once this time period has elapsed. The overall running time will be longer because it includes additional time for setup and teardown.

For example, to set a maximum running time of ten minutes:

```
TimeToRun: 10
```

MaxRequests

The maximum number of requests to send: the auto-tester stops issuing requests once this number has been reached. The final total of requests may be greater if additional requests are needed for setup and teardown.

Set this to zero to disable the request limit, and then the auto-tester will issue as many requests as fit into the allotted time period.

For example, to set a maximum of two thousand requests:

```
MaxRequests: 2000
```

MaxErrors

The maximum number of error responses to allow: the auto-tester stops issuing requests once this number has been reached.

An error in this context is not an API error indicated by a **4xx** (or even, sometimes, a **5xx**) response, which is to be expected if the profile exercises all execution paths through the implementation. An error here is one where the response to a request is inconsistent with the API definition, which is a defect. Common cases include:

- the status code is not documented
- the payload does not conform to the schema
- any 500 error

There should be no such errors in a mature implementation so the limit is typically set low, so that the profile can terminate early if they occur. You can set the limit to zero and disable this stopping condition, which might be appropriate for a development environment where you know that some operations have defects (or you can disable those operations from ever being called as described under Operations).

For example, to set the error limit to three:

```
MaxErrors: 3
```

Execution Control

ParallelRequests

If this is **true** then the auto-tester spawns threads to issue multiple requests concurrently, otherwise it issues just one request at a time. The concurrent option increases throughput and can be helpful in exposing synchronization issues in the API.

The number of concurrent threads is fixed and cannot be changed.

For example, to disable concurrent requests:

```
ParallelRequests: false
```

ErrorInjection

If this is **true** then the auto-tester issues a certain percentage of malformed requests to further exercise the validation logic of the API, otherwise it only issues requests that are well-formed according to the API definition.

The percentage of requests is specified as **ErrorPercent**.

For example, to enable malformed requests:

```
ErrorInjection: true
```

ErrorPercent

The percentage of malformed requests, when **ErrorInjection** is **true**.

For example, to include 2% of malformed requests:

```
ErrorPercent: 2.0
```

Resources

The AutoTest execution model is based around the notion of "resources", where a resource has a schema (of object type) and a set of operations (or methods). Resources are defined in the API extensions.

The auto-tester only exercises operations that belong to resources. To decide which operation to execute next, the auto-tester first picks a resource type at random, and then an operation from that type (again, at random).

You control the frequency with which resources are selected by assigning them weights. The selection frequency for a given resource is computed as the weight for that resource divided by the sum of all the weights.

A zero weight means that the resource will never be selected, and you can use this to exclude certain resources from testing; for example, when you know that they are not yet fully implemented. It is an error for all weights to be zero which would leave nothing to test.

Use the **Resources** key to assign weights to specific resources, and **ResourceDefault** to set the default weight for any resources not specified.

Resources

The weights assigned to specific resource types. The value is an object, where the keys are resource names, and the values are non-negative integer weights. Resource names must be declared in the API extensions.

For example, to increase the test focus on **Customer** operations, and exclude **Order** operations entirely:

```
Resources:
  Customer: 2
  Order: 0
```

ResourceDefault

The default weight for any resource type not mentioned explicitly under **Resources**. The weight can be any non-negative integer value, but there are two common use cases:

- if the weight is 1 then all resources are selected with equal frequency, except where specified otherwise under **Resources**
- if the weight is 0 then all resources are disabled, except for those specified otherwise under **Resources**

For example, to disable all resources by default:

```
ResourceDefault: 0
```

In this case there must be at least one non-zero weight under **Resources**.

Instances

Upper and lower bounds on the number of resource instances that should exist at any time. The value is an object, where the keys are resource names, and the values specify lower and upper bounds for those resource types. Resource names must be declared in the API extensions, and the bounds must be non-negative integers that together define a non-empty range. The upper bound may also be **unlimited** in which case the number of instances depends upon the balance of create and delete requests issued for that type.

The auto-tester keeps track of the instances it creates for each resource type, in order to provide valid references and avoid too many 404 responses, and makes best efforts to keep the number of instances within any specified bounds.

For example, to place an upper bound on the number of **Customer** instances that should exist at any time:

```
Instances:
  Customer:
    maximum: 25
```

InstanceDefault

The default instance bounds for any resource type not mentioned explicitly under **Instances**.

For example, to make the default unlimited:

```
InstanceDefault:
  minimum: 1
  maximum: unlimited
```

Operations

Once the auto-tester has selected a resource type, it uses a similar weighting strategy to choose an operation from that type.

You control the frequency with which operations are selected by assigning them weights. Use the **Operations** key to assign weights to specific operations, and **OperationDefault** to set the default weight for any operations not specified.

A zero weight disables an operation entirely, and if all the operations are disabled for a resource then the resource itself is also disabled.

Operations

The weights assigned to specific operations. The value is an object whose schema follows the pattern established by the **Paths** object in OpenAPI, but the values assigned to each operation are non-negative integer weights.

For example, to increase test focus on the **put_customer** operation, and avoid **patch_customer** completely:

```
Operations:
  /customers/{customer_id}:
    put: 10
    patch: 0
```

The special key _ can be used to match all methods defined on a path that are not called out explicitly. For example, to disable all but the **put_customer** operation:

```
Operations:
  /customers/{customer_id}:
    put: 10
    _: 0
```

Remember that the weights are interpreted only across operations within the same resource type, and not across all operations in the API, so the overall distribution is determined by both the weight on the resource and the weight on the operation.

OperationDefault

The default weight for any operations not mentioned explicitly under **Operations**. The value is an object where the keys are method names and the values are the default weights for those methods where they occur under any path. The special key _ matches all method names that are not listed separately.

For example, to disable all operations by default:

```
OperationDefault:
  _: 0
```

In this case there must be at least one non-zero weight under **Operations**.

Datatypes

Place here any custom rules that guide the auto-tester in generating values for operation parameters and payloads. These rules override the default rules derived from the API definition and any semantic annotations in the API extensions.

Rule syntax is described in Data Generation Rules.

Schemas

Data generation rules for named schemas found under **definitions** (OpenAPI 2.0) or **components/schemas** (OpenAPI 3.0).

For example, given the schema definition:

```
Movie:
  type: object
  properties:
```

```
    title:
      type: string
    release_date:
      type: string
      format: date
    language:
      description: Two-letter ISO 639-1 language code
      type: string
      pattern: '[a-z]{2}'
```

The default generation rule for the **language** property, derived from this schema, will produce random string values that match the specified pattern (two lower-case alphabetic characters) but many of these will not be valid language codes, potentially giving rise to an excessive number of 400 responses.

To override the default generation rule and specify instead some particular language codes sufficient for testing:

```
Datatypes:
  schemas:
    Movie:
      properties:
        language:
          enum:
            - en
            - fr
            - de
```

To inject a small percentage of invalid values:

```
Datatypes:
  schemas:
    Movie:
      properties:
        language:
          choice:
            - enum:
                - en
                - fr
                - de
              weight: 98
            - const: xx
              weight: 2
```

Operations

Data generation rules for operation parameters and payloads described by inline (or unnamed) schemas and types. The value is an object whose schema follows the pattern established by the **Paths** object in OpenAPI.

Note that the auto-tester only supports **path** and **query** parameters at present, and other parameter types are ignored.

For example, given these (abbreviated) operation definitions:

```
paths:
  /movies:
    get:
      parameters:
        - name: limit
          in: query
          description: Sets an upper bound on the number of movies returned
          schema:
            type: integer
    post:
      requestBody:
        content:
          application/json:
            schema:
              type: object
              allOf:
                - $ref: '#/definitions/Movie'
                - properties:
                    keywords:
                      type: array
                      items:
                        type: string
```

To set values for the **limit** query parameter, and the **keywords** property of the payload to **post**:

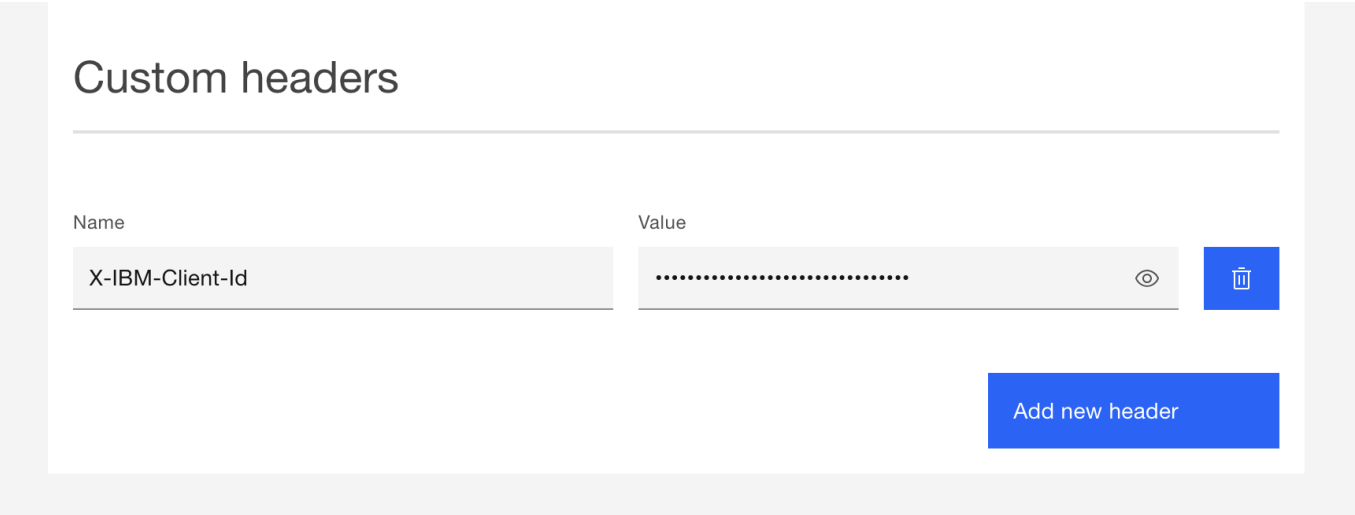
```
Datatypes:
  operations:
    /movies:
      get:
        parameters:
          - name: limit
            in: query
            data:
              # pick a random value between 0 and 500 (inclusive)
              minimum: 0
              maximum: 500
      post:
        requestBody:
          content:
            application/json:
              data:
                properties:
                  keywords:
                    # pick up to 3 items from the following list
                    items:
```

```
                    enum:
                      - avant-garde
                      - dystopia
                      - epic
                      - postmodern
                      - remake
                      - shootout
                  minItems: 0
                  maxItems: 3
```

Profile Security

Security is where you set credentials for the API under test. The auto-tester supports only **Basic** authentication (username and password) and **Bearer** (or **Token**) authentication; it does not support other authentication methods such as **OAuth,** or the use of custom headers.

Select your security type from the dropdown and enter the required information:



Security Type	Description	Credentials
None	Unsecured endpoint	n/a
Basic	Basic HTTP authentication	Username/Password
Basic-url	Same as **Basic** but omits the word `Basic` from the Authorization header	Username/Password
Bearer	Bearer (or Token) authentication	Token

If you provide incorrect credentials then they will not prevent the profile from running, but you can expect to see all requests fail, typically with the response **401 Unauthorized** or **403 Forbidden.**

If you provide a bearer token then be sure that it has a sufficient lifetime to cover the full period of the test, which is determined by the stopping criteria in the profile configuration. Otherwise, once the token expires, you can expect to see authentication failures as described earlier.

Custom headers

You can also confiure custom security headers should your APIs require them for authentication/authorization. Simply add the required header(s) and the appropriate value(s) under the custom headers section like so:

Data Generation Rules

This feature is available only in API Connect Enterprise as a Service

Data generation rules guide the auto-tester in choosing values to populate the parameters and payloads of its requests.

There are default rules derived from the API definition and extensions, but sometimes you want to override these, either to improve the general accuracy of the auto-tester or to tailor its requests to a specific use case, and you do that by adding custom rules to the Datatypes section of the profile configuration.

A data generation rule binds a **data generator** to a schema or type in the API definition such that, when the auto-tester assembles the data for a request and encounters that schema or type, it uses the generator to provide an appropriate value at that point.

Data generators

A **data generator** describes a never-ending sequence of values, and whenever the auto-tester calls on a generator it takes the next value from the sequence.

The syntax for generation rules reuses terms from JSON Schema where the implied constraints on a schema are sufficient to guide the auto-tester in generating conformant values. Such constraints occurring in the API definition help inform the default rules.

Constant

The **constant** generator always returns the same value, which can be of any simple type.

```
const: 0

# ==> 0, 0, 0, ...

const: Thursday

# ==> "Thursday", "Thursday", "Thursday", ...
```

Enumeration

The **enumeration** generator returns values selected at random from a given list, which can be of any simple type.

```
enum:
  - 0
  - 1
  - 2

# ==> 1, 0, 2, 0, ...

enum:
  - Thursday
  - Friday
  - Saturday

# ==> "Friday", "Saturday", "Saturday", ...
```

Pattern

The **pattern** generator returns string values that match a given regular expression.

```
pattern: '[0-9]{3}'

# ==> "884", "924", "121", ...

pattern: '[a-z][a-z_]{0,15}'

# ==> "dbe", "kg_cfsv", "dhbfgbjxavmsaxq", ...
```

Range

The **range** generator returns numeric values uniformly distributed over a given range (inclusive).

```
minimum: 0
maximum: 10

# ==> 10, 6, 8, ...
```

If either endpoint is omitted then it defaults to the most negative or most positive value of the type:

```
minimum: 0

# ==> 10029625, 3162517758, 841054690, ...
```

Semantic

The **semantic** generator returns values that conform to some pre-defined semantic category, covering names, addresses, credit card numbers, etc. The set of categories is the same as that allowed in the API extensions.

```
semantic: email

# ==> "herbertschaden@fahey.net", "emmyfarrell@cruickshank.com", "vilmaprohaska@zboncak.org", ...

semantic: first_name

# ==> "Antwan", "Connie", "Modesto", ...
```

Resource

The **resource** generator returns values that are unique identifiers of resource instances of a given type, selected at random from the pool of existing instances. The identifier of an instance is taken from the **id_name** property of the resource type defined in the API extensions and its type and format will vary accordingly.

```
resource: Customer

# ==> "e5537298-9041-47fc-b97e-c910d8f9d971", "f60521c8-2ccb-4036-a742-9f350271675f", "e5537298-9041-47fc-b97e-c910d8f9d971",
...
```

Array

The **array** generator returns array values whose contents are populated from a data generator defined recursively. The length of the array is chosen at random between **minItems** and **maxItems** inclusive.

```
items:
  pattern: '[0-9]{3}'
minItems: 3
maxItems: 3

# ==> ["770", "496", "219"], ["431", "895", "331"], ["864", "130", "204"], ...

items:
  enum:
    - 0
    - 1
minItems: 0
```

```
maxItems: 5

# ==> [], [1, 0, 1, 1], [0], ...
```

Object

The **object** generator returns object values whose properties are populated from named data generators, defined recursively.

```
properties:
  x:
    minimum: 0
    maximum: 100
  y:
    minimum: 0
    maximum: 100

# ==> {"x": 59, "y": 63}, {"x": 22, "y": 8}, {"x": 95, "y": 57}, ...
```

```
properties:
  code:
    pattern: '[0-9]{3}'
  language:
    enum:
      - en
      - fr
      - de

# ==> {"code": "452", "language": "fr"}, {"code": "504", "language": "en"}, {"code": "846", "language": "fr"}, ...
```

If a property is not required by the target schema then it may be marked with an `optional` attribute which specifies a frequency (between `0.0` and `1.0`) that determines how often the property is included in the generated object (where 0 means never, and 1 means always).

```
properties:
  code:
    pattern: '[0-9]{3}'
  language:
    optional: 0.5
    enum:
      - en
      - fr
      - de
  tag:
    optional: 0.0

# ==> {"code": "452", "language": "fr"}, {"code": "504", "language": "en"}, {"code": "846"}, ...
```

Choice

The **choice** generator returns values selected at random from a given list of data generators, using optional weights to bias the outcome. The alternatives must be simple generators, which excludes `array` and `object` generators.

```
choice:
  # bias the selection towards English
  - const: en
    weight: 5
  - const: fr
  - const: de

# ==> "en", "en", "en", ..., "de", "en", ...
```

```
choice:
  # normal values in the range 1-10
  - minimum: 1
    maximum: 10
    weight: 98
  # with a small percentage of outliers
  - const: 999
    weight: 2

# ==> 6, 3, 9, 1, ..., 999, 6, ...
```

Data generation rules

A **data generation rule** binds a data generator to a schema occurring in the API definition so that the auto-tester knows how to generate values for that schema in an API call. Rules are specified in the Datatypes section of the profile configuration, and override the default rules derived from the API definition and extensions.

Schemas occur widely in the OpenAPI specification, but there are three key locations which have most relevance to the auto-tester where the profile allows override rules:

- Named schemas
- Parameters
- Inline request bodies

Named schemas

A schema rule assigns a data generator to a named schema from the API definition, found either under `definitions` (OpenAPI 2.0) or `components/schema` (OpenAPI 3.0). The auto-tester will use the specified generator wherever the named schema occurs in a request.

Schema rules appear in the schemas section of the profile configuration, under `Datatypes`.

Because this is an *override,* the generator may be incomplete for the original schema, and the auto-tester will fall back to using the default rules to cover any gaps. In particular, if the schema describes an object type then the generator need only name a subset of the object properties, and the auto-tester will apply the override for those properties but use default rules for the rest.

For example, given this named schema in the API definition:

```
Movie:
  type: object
  properties:
    title:
      type: string
    release_date:
      type: string
      format: date
    language:
      description: Two-letter ISO 639-1 language code
      type: string
      pattern: '[a-z]{2}'
```

The default rule derived from the schema returns values such as:

```
{
  "title": "mkLHM22Ohabb6YG4-wdZFUwxQa7dn",
  "release_date": "2018-09-14",
  "language": "jq"
}
```

You can refine this by overriding the default rules for the **title** and **language** properties:

```
Datatypes:
  schemas:
    Movie:
      properties:
        title:
          semantic: sentence
        language:
          enum:
            - en
            - fr
            - de
```

This rule binds an object generator (introduced by the keyword **properties**) to the schema named **Movie** which -- combined with the default rule for **release_date** -- returns values such as:

```
{
  "title": "What dog everybody am myself hourly meeting how group over example her",
  "release_date": "2094-06-31",
  "language": "de"
}
```

Parameters

A parameter rule binds a data generator to a named parameter within an operation found under **paths** in the API definition.

Parameter rules appear in the operations section of the profile configuration, under **Datatypes**.

For example, given this parameter definition on **GET /movies** in the API definition that restricts the number of movies returned in a single call:

```
paths:
  /movies:
    get:
      parameters:
        - name: limit
          in: query
          description: Sets an upper bound on the number of movies returned
          schema:
            type: integer
```

The default rule derived from this definition will return values from the full integer range, but you can override this with a rule in the profile configuration that specifies a more realistic range, with occasional outliers to check the validation logic:

```
Datatypes:
  operations:
    /movies:
      get:
        parameters:
          - name: limit
            data:
              choice:
                - minimum: 1
                  maximum: 500
                  weight: 95
                - const: 0
                  weight: 3
                - const: 8000000
                  weight: 2
```

The format of the rule follows the format of the original definition but with the keyword **data** in place of **schema** to introduce the data generator.

In OpenAPI, a parameter is uniquely identified by a name *and a location* (so the same name could be used in, say, both query and header) so the parameter rules allow the **in** property as optional where needed to disambiguate. It's not used in this example because the query parameter is the only one named **limit**.

The auto-tester only supports parameters of type **query** and **path** at present (and **body** in OpenAPI 2.0). Rules bound to other parameter types are ignored.

Request body

A request body rule binds a data generator to the body of a request where the corresponding schema is specified directly as part of the operation in the API definition, rather than via a reference to a named schema.

Request body rules appear in the operations section of the profile configuration, under **Datatypes**.

For example, given this definition of the payload to a **POST** request:

```
paths:
  /movies:
    post:
      requestBody:
        content:
          application/json:
            schema:
              type: object
              allOf:
                - $ref: '#/components/schemas/Movie'
                - properties:
                    keywords:
                      type: array
                      items:
                        type: string
```

The following rule generates some appropriate keywords to attach to a new movie (where the movie itself is covered by the rules discussed earlier):

```
Datatypes:
  operations:
    /movies:
      post:
        requestBody:
          content:
            application/json:
              data:
                properties:
                  keywords:
                    # pick up to 3 items from the following list
                    items:
                      enum:
                        - avant-garde
                        - dystopia
                        - epic
                        - postmodern
                        - remake
                        - shootout
                    minItems: 0
                    maxItems: 3
```

As with the parameter rules, the format follows that of the original definition but with **data** in place of **schema**. The definition is in the style of OpenAPI 3.0, but the rule can work for OpenAPI 2.0 as well as long as the content type is consistent; alternatively, starting from an OpenAPI 2.0 definition, you can use a **body** parameter rule to specify the payload, but that does not work for 3.0.

Testing an API with the Policies editor

IBM® API Connect provides a basic test environment in the Policies editor so that you can ensure that your APIs are defined and implemented correctly.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note:

- If you are testing an OpenAPI 2.0 API, you can use either the Policies editor test tool described here, or you can use the Test tab. If you are testing an OpenAPI 3.0 API, only the Test tab is available; see Using the Test tab to debug your API.
- If you are testing an API that contains references to API properties, only those references that are defined inside the API assembly are resolved and replaced with their corresponding values when you invoke the API in the assembly test tool; property references that are defined outside of the API assembly are not resolved. For more information on API properties, see Setting API properties (OpenAPI 2.0) or Setting API properties (OpenAPI 3.0).
- Due to Cross-Origin Resource Sharing (CORS) restrictions, the assembly test tool cannot be used with the Chrome or Safari browsers on the macOS Catalina platform.

Procedure

To test an API, complete the following steps.

1. If you are using API Designer, set the mode to Online using the Options menu ⋮ on the main page.
2. In the navigation pane, click Develop, then select the APIs tab.
3. Click the title of the API that you want to work with.
4. Click the Gateway tab then, in the navigation pane, click Policies.
5. If you are testing the API for the first time and, when you created the API definition, you selected the Activate API option, your test setup will already be configured and you can proceed immediately to the next step to test your API. Otherwise, click Offline to toggle the API to the Online state. If you are retesting your API after making changes, the modified API will have been republished automatically on saving.
6. Click the Test icon.
   Note:
   - The Test icon is active only if you have toggled your API to the Online state, as described in step 5.
   - The Catalog, Product, Plan, and application details displayed in the Setup pane reflect your configured API testing preferences; see Specifying the testing preferences for an API,

7. In the Operation section, select the API operation that you want to test, then click Invoke.
   The API response is displayed in the Response section.
   Note: If you receive a message relating to an untrusted certificate, click the link provided, accept the certificate, then return to the test environment and click Invoke again. The message also mentions a lack of CORS support on the server, but this is just one possible cause for the connection failing.

Testing an API with the Local Test Environment

Use the Local Test Environment (LTE) to test APIs on your local machine, without the need to connect to an API Connect management server. The Local Test Environment is a lightweight API Manager running on your local machine. It allows you to rapidly test APIs locally.

API Connect provides the following methods for testing an API on your local machine:

- Invoke the API from the API Designer UI application running in Online mode as described in Testing an API.
- Call the API in the Local Test Environment with a cURL command, as described in the following sections.

Prerequisites

- The API Connect developer toolkit, including the API Designer user interface, installed. For installation and running instructions, see Installing the toolkit.
- The Local Test Environment and the API Designer must be from the same API Connect fix pack release in order for them to work together.
- Docker installed.
  Note: The Local Test Environment is not supported with Docker Version 18.09.x.
- A minimum of 4 GB of RAM available to Docker if a single gateway type is used, or 6 GB if both the DataPower® API Gateway and DataPower Gateway (v5 compatible) are used.
  Note: As you increase the number of APIs that are published to your gateways, you will need to allocate further memory to Docker. You will also need to start the Local Test Environment with a larger database; see **`apic-lte start`**.
- If you are using Windows, ensure that your C: drive (or the drive on which your HOME directory is located, if different), is enabled as a shared drive so that the Local Test Environment files are accessible to the Docker containers.

Installing the Local Test Environment

There are two options for installing the Local Test Environment:

- Each user downloads the Local Test Environment images to their local machine and installs the Local Test Environment from there.
- One user downloads the Local Test Environment images and uploads them to a private Docker registry, from where any user can install the Local Test Environment.

To install the Local Test Environment from your local machine, complete the following steps:

1. Open a browser and visit the API Connect announcement page, search for your product version, and locate the "Downloads" table on the product announcement page. In the table, click the link to download each of the following files:
   - apic-lte-images-*version*.tar.gz, which contains all required Docker images.
     Example: apic-lte-images-10.0.2.tar.gz
   - apic-lte-*platform*-*version*, which are binary files for the macOS, Linux®, and Windows platforms.
     Examples:
     - macOS: apic-lte-osx-10.0.2
     - Linux: apic-lte-linux-10.0.2
     - Windows: apic-lte-win-10.0.2
2. On the macOS or Linux platform, use the **`chmod`** command to make the binary file executable; for example:

   ```
   chmod +x linux-apic-lte
   ```

3. Load the Docker images into your local Docker image repository by entering the following command:

   ```
   docker load < apic-lte-images.tar.gz
   ```

Note: In all Local Test Environment commands that are used on the remainder of this page, replace *platform* with **`macOS`**, **`linux`**, or **`windows`**, depending on your platform, as follows:

- macOS: replace ***`platform`*`-apic-lte`** with **`osx-apic-lte`**
- Linux: replace ***`platform`*`-apic-lte`** with **`linux-apic-lte`**
- Windows: replace ***`platform`*`-apic-lte`** with **`win-apic-lte`**

To upload the Local Test Environment images to a private Docker registry, complete the following steps:

1. Download the **`IBM_API_CONNECT_LOCAL_TEST_ENVIRO.zip`** file as described in step 1.
2. Distribute the appropriate binary file to all users, according to the platform.
3. Upload the Local Test Environment to your private Docker registry; enter the following command:

   ***`platform`*`-apic-lte registry-upload apic-lte-images.tar.gz registry_host`**

   where *registry_host* is the host name or IP address of your private Docker registry. Now, any user can install and run the Local Test Environment as follows:
   a. If the private Docker registry requires authentication, log in by entering the following command:

      `docker login registry_host`

   b. Load the Docker images into your local Docker image repository by entering the following command:

      ***`platform`*`-apic-lte init registry_host`**

Starting the Local Test Environment

1. Start the Docker images by running the following command:

   ```
   platform-apic-lte start
   ```

   Note:
   - By default, the `platform-apic-lte start` command starts only a DataPower API Gateway. To also start a DataPower Gateway (v5 compatible), enter the following command:

     ```
     platform-apic-lte start --datapower-gateway-enabled --datapower-api-gateway-enabled
     ```

   - The Local Test Environment might fail to start with an error message that includes the strings `Error: certificate is not yet valid` and `CERT_NOT_YET_VALID`. The most likely cause is that the date and time setting is incorrect on the machine that is the running the Local Test Environment. Ensure that the date and time setting is correct, before attempting the start command again. If you are using Docker for Windows, the clock in the Docker containers can become out of sync with the system clock, especially after a machine has been put in sleep mode. In this case, restarting Docker should fix the clock discrepancy; for more information, see https://github.com/docker/for-win/issues/4526.
   - By default, the LTE starts with an empty backend database that does not contain the APIs and Products that might have been published during an earlier run of the LTE. To start the LTE with the backend database that was used during the previous run, use the flag `--keep-config`, for example, `platform-apic-lte start --keep-config`. When you use `--keep-config` any other flag that is specified for the start is ignored. Instead the same flags that were used during the earlier start are used, in particular the same gateways are enabled.
2. Verify that the Local Test Environment is installed and running correctly by running the following commands:
   a. Check the status of the LTE components:

      ```
      platform-apic-lte status
      ```

      This output from this command shows the status of all components, and provides endpoint and authentication details, and should be similar to the following:

      ```
      Container                       Status
      ---------                       ------
      apic-lte-apim                   Up 3 minutes
      apic-lte-datapower-gateway      Not Running
      apic-lte-datapower-api-gateway  Up 2 minutes
      apic-lte-db                     Up 3 minutes
      apic-lte-juhu                   Up 3 minutes
      apic-lte-lur                    Up 3 minutes

      - Platform API url: https://localhost:2000
      - Admin user: username=admin, password=7iron-hide
      - 'localtest' org owner: username=shavon, password=7iron-hide
      - 'localtest' org sandbox test app credentials client id: 80963e74076afe50d346d76401c3c08a
      - Datapower API Gateway API base url: https://localhost:9444/localtest/sandbox/
      ```

   b. Log in to the management server:

      ```
      apic login --server localhost:2000 --username shavon --password 7iron-hide --realm provider/default-idp-2
      ```

      This command confirms that you can log in to the management server, and the response should be as follows:

      ```
      Logged into localhost:2000 successfully
      ```

      Known issue: If you receive an error during the login, stop and then restart the LTE; then log in again.

Note: To configure the toolkit credentials for Local Test Environment, use the following command:

```
apic client-creds:set ~/.apic-lte/credentials.json
```

Preparing an API for testing in the Local Test Environment

To prepare an API for testing in the Local Test Environment, you must publish it to the Sandbox Catalog in the Local Test Environment. If you want to test an API that you already published, proceed to Testing an API in the Local Test Environment., otherwise, complete the following steps:

1. Launch the API Designer user interface with the following command:

   ```
   APIC_DESIGNER_CREDENTIALS=~/.apic-lte/credentials.json <path-to-designer>
   ```

2. Open the required local directory; this is the directory in which your API and Product definition files will be stored.
3. Connect to the Local Test Environment. If you haven't previously connected to the Local Test Environment, click Add Another Cloud, then complete the following steps:
   a. In the HOST URL field, enter `https://localhost:2000`, then click Next.
   b. In the Username field, enter `shavon`, in the Password field enter `7iron-hide`, then click Sign in.
      Note:
      - If you are not able to connect to the Local Test Environment using `https://localhost:2000`, enter `https://127.0.0.1:2000` instead in the HOST URL field.
      - If you receive an error during the login, stop and then restart the LTE; then log in with API Designer again.

   If you have previously connected to the Local Test Environment, click the existing tile to log in immediately.

   The API Designer welcome page opens.

4. Click Develop APIs and Products, then click the API that you want to test. For details on how to configure an API definition, see Developing your APIs and applications.
5. You must publish your API before testing. For instructions on how to publish an API, See Publishing a draft Product
   Note: Whenever you make any changes to an API, you must republish it before retesting.

Testing an API in the Local Test Environment.

To test an API in the Local Test Environment, issue a REST API call to the following URL:

```
https://localhost:9444/localtest/sandbox/basepath/operation_path?client_id=lte_client_id
```

where:

- *basepath* is the base path that is configured in the API definition.
- *operation_path* is the path for the operation that you want to invoke, as configured in the API definition.
- *lte_client_id* is the client ID for the test application in the local test environment, as returned by the **platform-apic-lte status** command in step 2.

The following example show how to test the API that is created in the tutorial Creating a proxy REST API definition, by using the **curl** utility; the API returns the details of bank branches:

```
curl -k https://localhost:9444/localtest/sandbox/branches/details?client_id=80963e74076afe50d346d76401c3c08a
[{"id":"0b3a8cf0-7e78-11e5-8059-a1020f32cce5","type":"atm","address":{"street1":"600 Anton Blvd.","street2":"Floor

```

Local Test Environment commands

The following table summarizes the Local Test Environment commands; use the **help** command to get full usage details for any command.

Table 1. Local Test Environment command summary

Command	Description
platform-apic-lte help *command*	Display help information for any command.
platform-apic-lte init	Download the Local Test Environment Docker images.
platform-apic-lte start	Start the Local Test Environment Docker images. Use the **--database-max-heap-size** parameter to set the size of the Local Test Environment database, in bytes; for example: **linux-apic-lte start --database-max-heap-size 4096M** **linux-apic-lte start --database-max-heap-size 1G** **linux-apic-lte start --database-max-heap-size 1048576K** **linux-apic-lte start --database-max-heap-size 1073741824** The default value is **1024M**. Tip: By default, the **platform-apic-lte start** command deletes all previous data and re-initializes the Local Test Environment configuration, so all your previous configuration, including published Products, is deleted. To retain the previous configuration, and to apply the same command parameters that were used in the previous **platform-apic-lte start** command, supply the **--keep-config** parameter.
platform-apic-lte status	Display status information for the Local Test Environment components, and endpoint and authentication details.
platform-apic-lte stop	Stop the Local Test Environment Docker images.
platform-apic-lte version	Display Local Test Environment version information.

Troubleshooting the Local Test Environment

You can consult the log file for each Local Test Environment microservice or database by using the following command:

```
docker logs container-name
```

where *container-name* is one of the following:

- **apic-lte-juhu**: the authentication gateway
- **apic-lte-apim**: the API Management service
- **apic-lte-lur**: the Local User Registry
- **apic-lte-db**: the Postgres database of the API Management service
- **apic-lte-datapower-api-gateway**: the DataPower API Gateway
- **apic-lte-datapower-gateway**: the DataPower Gateway (v5 compatible)

You can access the gateway logs in either of the following ways:

- Use the gateway administration web UI:
  1. Open the page **https://localhost:*web_ui_port*** in a browser; for details of the required port value, see Local Test Environment port values.
  2. Select the apiconnect domain and the WebGUI interface, and log in with user name `admin` and password `admin`.
  3. Click View Logs.
- Use the gateway administration CLI:

1. Open an SSH connection by using the following command:

   ```
   ssh -p gateway-ssh-port localhost
   ```

   For details of the required port value, see Local Test Environment port values. The user name is `admin` and the password is `admin`.
2. Enter the command **switch domain apiconnect**.
3. To view the gateway log, enter the command **show log**.
4. To view the log for the communication between the gateway and the API management system, enter the command **show logging gwd-log**.

Local Test Environment port values

If any of the default port values for the Local Test Environment components conflict with ports already in use on your system, you can change them when you start the Local Test Environment by passing one or more `--component port_value` parameters to the `platform-apic-lte start` command, where:

- *component* is the Local Test Environment component whose port value you want to change.
- *port_value* is the required value.

For example:

```
platform-apic-lte start --datapower-api-gateway-api-port 9445
```

The following table lists the components, together with the corresponding *component* parameters, and the default port values:

Component	*component* parameter	Default port value
DataPower API Gateway API port	`datapower-api-gateway-api-port`	9444
DataPower API Gateway API Connect service port	`datapower-api-gateway-apic-service-port`	3001
DataPower API Gateway REST management port	`datapower-api-gateway-rest-management-port`	5555
DataPower API Gateway SSH port	`datapower-api-gateway-ssh-port`	9023
DataPower API Gateway administration web UI	`datapower-api-gateway-web-gui-port`	9091
DataPower API Gateway XML management port	`datapower-api-gateway-xml-management-port`	5551
DataPower Gateway (v5 compatible) API port	`datapower-gateway-api-port`	9443
DataPower Gateway (v5 compatible) API Connect service port	`datapower-gateway-apic-service-port`	3000
DataPower Gateway (v5 compatible) REST management port	`datapower-gateway-rest-management-port`	5554
DataPower Gateway (v5 compatible) SSH port	`datapower-gateway-ssh-port`	9022
DataPower Gateway (v5 compatible) administration web UI	`datapower-gateway-web-gui-port`	9090
DataPower Gateway (v5 compatible) XML management port	`datapower-gateway-xml-management-port`	5550
Platform API port	`platform-api-port`	2000

Testing an API with the Explorer tab

Use the Explorer tab in the API editor to see how your APIs look to a consumer in the Developer Portal. You can also use the Try it tool to test the behavior of the API.

Before you begin

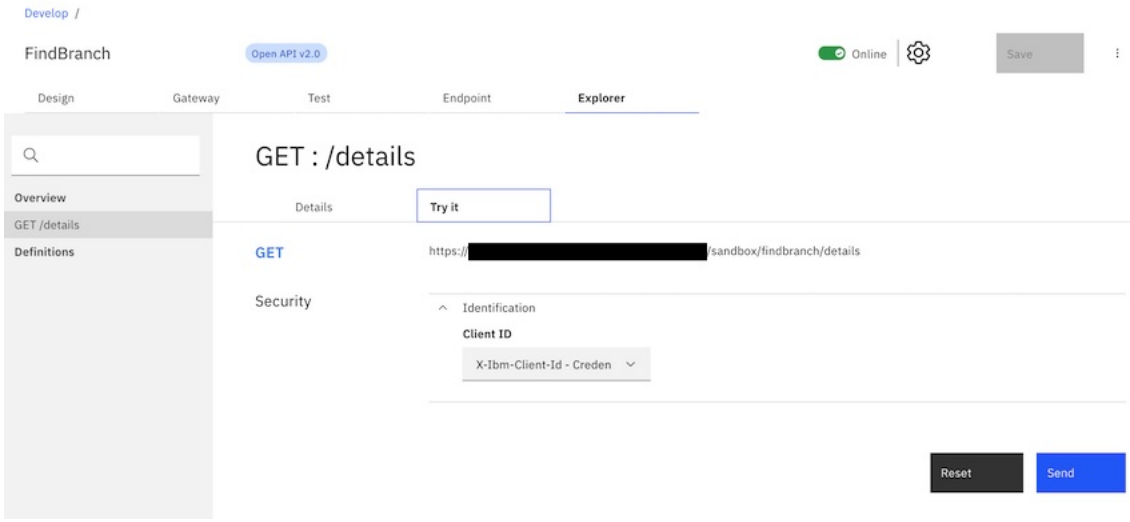
To test an API in the Try it test tool, the API must be auto-published. If the API is not auto-published, the Try it tool isn't enabled in the Explorer.

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

About this task

The Explorer tab in the API editor of the API Designer UI and API Manager UI enables you to view how your APIs look to an API consumer in the Developer Portal. You can check the descriptions of the different artifacts, and as well as any schemas or examples, and you can also test the behavior of the API by using the Try it tool.

Note:



- You cannot use the Try it tool to test non-enforced APIs.

Procedure

To test an API by using the Try it tool, complete the following steps.

1. If you are using API Designer, set the mode to Online using the Options menu ⋮ on the main page.
2. In the navigation pane, click Develop, then select the APIs tab.
3. Click the title of the API that you want to work with.
   The API editor is displayed.
4. Click the Explorer tab.
   An Overview of the API is displayed.
5. Click the API artifacts in the side menu bar to explore the operations and definitions that are available in the API, including reviewing any examples and schemas.
6. To test API behavior, click an operation in the side menu bar, and click the Try it tab.

The test pane for the operation is displayed, as shown in the following example:

7. Provide any required API parameters, and click Send.
   The API response is displayed in the Response section.
   Note: If you receive a message relating to an untrusted certificate, click the link provided, accept the certificate, then return to the test environment and click Send again.

What to do next

When you are happy with the look and behavior of your API, you can stage the API to a Product in a Catalog. For more information, see Staging an API.

Staging an API

The graphical wizard provides an option that adds the API to a Product and stages the Product in a Catalog. When a Product is in the staged state, it is not yet visible to, or subscribable by, any developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be staged only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.

Ensure that the Catalog has at least one gateway service configured.

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Stage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Staging is not available when working offline in API Designer.

A Catalog is a staging target, and behaves as a logical partition of the DataPower® Gateway, and the Developer Portal.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either `X-IBM-Client-Id` or `X-IBM-Client-Secret`.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of `$ref` properties), and ensuring these are valid JSON Pointers within the file.

Note: If the OpenAPI file that defines your API uses a `$ref` field to reference a fragment of OpenAPI code that is defined in a separate file, the `$ref` field is replaced with the contents of the target file before the product that contains the API is staged or published (the `$ref` field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
   The Develop page opens.

2. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
3. You can stage an API either from the Develop listing page, or from within the API definition itself.
    a. To stage an API from the Develop listing page, click the options menu icon ⋮ alongside the required API, and then select Stage.
    b. To stage an API from within the API definition, complete the following steps:
        i. Click the title of the API that you want to work with.
        ii. Click the options menu icon:

        iii. Click Stage.
4. Choose one of the following actions:
    - To stage the API by adding it to a new Product:
        - Select New Product - Publish using a new product.
        - When prompted, enter a Title and Version.
        - The Product Name is automatically entered. The Name is the used to refer to the product in CLI commands. See the toolkit CLI reference documentation.
        - Click Next.
    - To stage the API by adding it to an existing Product:
        - Select Existing Product - Publish using an existing product
        - Select the Product you want to use.
        - Click Next.
5. On the Stage To page, select the Catalog to which you want to stage the Product.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.

6. If, when the staged Product is subsequently published, you want it to be published only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
7. Click Stage.

Results

Your Product is staged to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you staged the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Staged.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to stage Products in the Catalog, an approval request is sent, and the Product moves to the Pending state; the Product is staged when the request is approved. If approval is not required, the Product is staged immediately.

For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Publishing an API

The user interface provides an option that adds an API to a Product and publishes the Product in a Catalog. Publishing a draft Product makes the APIs in that Product visible on the Developer Portal for use by application developers. The syndication feature in IBM® API Connect means that if Spaces are enabled for a Catalog, Products can be published only to a Space within that Catalog.

Before you begin

Ensure that you have a Catalog to stage to in the API Manager or API Designer user interfaces (UI). For more information, see Creating and configuring Catalogs.

Ensure that the Catalog has at least one gateway service configured.

Note: All references in this topic to a Catalog can also be applied to Spaces in a Catalog, unless specified otherwise. For more information about Spaces, see Using syndication in API Connect.
To complete the Product management tasks that are described in this topic, you must either be the owner of the API provider organization, or be assigned Product > Manage permission for the target Catalog or Space. For information on configuring Product management permissions for a Catalog or Space, see Creating and configuring Catalogs or Managing user access in a Space.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI. Publishing is not available when working offline in API Designer.

Validation of the API definition file occurs during the staging or publishing process. The following validation occurs:

- Validation against the OpenAPI schema by using the API Dev Tools Swagger Parser (https://www.npmjs.com/package/@apidevtools/swagger-parser).
- Validation against IBM extension properties.
- Semantic validation, which includes the following types of validation:
  - Ensuring that if an OpenAPI is enforced by an API Connect Gateway, then the scheme must be HTTPS, or the parameter name for an API key security scheme in the header must be either **`X-IBM-Client-Id`** or **`X-IBM-Client-Secret`**.
  - Ensuring that if the OpenAPI is not enforced by an API Connect Gateway, then a "host" must be provided.
  - De-referencing of local references in the definition file (that is, values of **`$ref`** properties), and ensuring these are valid JSON Pointers within the file.

Note: Products that contain an API with a Swagger property using **regex** that include lookahead assertions, such as "**`(?`**" cannot be validated or published. An error message is returned. For example:

```
Product has not been published!
The multipart 'openapi' field contains an OpenAPI definition with validation errors.
    definitions.properties.pattern Does not match format 'regex' (context: (root).definitions.properties.pattern, line: 0, col:
0)
400
```

Note: If the OpenAPI file that defines your API uses a **`$ref`** field to reference a fragment of OpenAPI code that is defined in a separate file, the **`$ref`** field is replaced with the contents of the target file before the product that contains the API is staged or published (the **`$ref`** field is supported only if you are using the API Connect developer toolkit). For more information, see Using $ref to reuse code fragments in your OpenAPI files.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. **Optional:** If you have accounts on multiple provider organizations, you can select a new provider organization for staging and publishing from the Organization menu.
3. You can publish an API either from the Develop listing page, or from within the API definition itself.
   a. To publish an API from the Develop listing page, click the options menu icon ⋮ alongside the required API, and then select Publish.
   b. To publish an API from withing the API definition, complete the following steps:
      i. Click the title of the API that you want to work with.
      ii. On the Develop page, click the Menu icon (three dots), adjacent to the API that you want to edit, and then click Edit API.
      iii. Click the Test tab and then select Target Configuration.
      The Preferences dialog box is displayed.
      iv. Set the Auto-publish option to On.
   Remember: The auto publish setting is not associated with individual APIs. If you activate the auto publish setting for one API, it applies to all other APIs, regardless of the catalogue or the gateway. Therefore, it is highly recommended that you select a single set of settings for all the APIs instead of changing the settings individually for each API.
4. Choose one of the following actions:
   - To publish the API by adding it to a new Product:
     - Select New Product - Publish using a new product.
     - When prompted, enter a Title and Version.
     - The Product Name is automatically entered. The Name is the used to refer to the product in CLI commands. See toolkit CLI reference documentation.
     - Click Next.
   - To publish the API by adding it to an existing Product:
     - Select Existing Product - Publish using an existing product
     - Select the Product you want to use.
     - Click Next.
5. Select the Catalog to which you want to publish the Product.
6. If Spaces have been enabled in the selected Catalog, select the Space that you require.
   Note: The Catalogs that you can select from are those that are defined for the management server and provider organization that you are connected to.
   If you are using the API Manager user interface, the connection details are determined by the API Manager URL that you open, and the user ID with which you log in. If you are using the API Designer user interface, you provide the management server details and user ID in the login window that opens when you first launch API Designer; see Logging into API Designer.

   For details of how to create a Catalog in a provider organization, see Creating and configuring Catalogs.
7. If you want to publish the Product only to selected gateway services, select Publish to specific gateway services, then select the required gateway services. Only the gateway services whose type matches the gateway type setting for the Product are listed. For information on gateway types, see API Connect gateway types.
8. Click Publish.

Results

Your Product is published to a Catalog. You can view the state of the Product in the Catalog in API Manager. If you published the product from API Designer, ensure you are logged into API Manager with the same user name and password that you used for API Designer. Click  Manage in the API Manager UI, then select the required Catalog. The Product is shown with a state of Published.

For information about the lifecycle of a product, see The Product lifecycle.

If approval is required to publish Products in the Catalog, a publish approval request is sent, and the Product moves to the Pending state; the Product is published in the Catalog when the request is approved. If approval is not required, the Product is published immediately.

Note: If approval is required to stage Products to the Catalog, a stage approval request is sent. When the request is approved, the Product moves to the staged state and must be separately published in the Catalog. For information on publishing a staged Product in a Catalog, see Publishing a Product.
For information on configuring Product lifecycle approvals for a Catalog, see Creating and configuring Catalogs. For information on approving requests, see Approving Product lifecycle and subscription requests.

If the Product contains no Plans, a Plan called Default Plan is added automatically to the Product in the Catalog.

Notes:

- If an OpenAPI 3 API contains a response wildcard (which is not supported), publishing is disabled for that API. You must correct the problem before you can publish the API.
- If the Product contains an API that includes a user-defined policy that has not been imported into this Catalog, the publish will fail. The user-defined policy must be available in the required Catalog for the Product to be published successfully. For detailed instructions on how to import a user-defined policy into a Catalog, see Importing a user-defined policy into a Catalog.

Creating a new version of an API definition

You can create multiple versions of an API definition and edit the versions independently by using IBM® API Connect.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

Note: If you want to publish a modified API to a production Catalog, you **must** create a new version of the API. You cannot publish an API to a production Catalog if there is already a published API with the same name and version.

Procedure

To create a new version of an API definition, complete the following instructions:

1. In the navigation pane, click Develop, then select the APIs tab.
2. You can create a new version of an API definition either from the Develop page, or from within the API definition itself.
   a. To create a new version of an API definition from the Develop page, complete the following steps:
      i. Alongside the API version that you want to work with, click the options icon ⋮, then click Save as a new version. The Save API as a new version window opens.
      ii. Enter your new version number, then click Save.
   b. To create a new version of an API definition from within the API definition itself, complete the following steps:
      i. Click the title of the API definition that you want to create a new version of.
      ii. Click the options menu icon:

      iii. Click New Version, enter your new version number, then click Submit.

Note: The version corresponds to the `info.version` property value of the API's OpenAPI definition. The `version.release.modification` version numbering scheme is recommended, for example `1.0.0`.

Results

You have created a new version of your API definition, which you can now edit independently of other versions. Each version of the API definition is listed separately on the APIs and Products page.

Related tasks

- Creating an API definition

Updating an API definition from a file

You can update an API by uploading a .yaml or .json file that contains the OpenAPI definition for the revised API.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

The update operation completely replaces the previous API definition.

Procedure

To update an API from a file, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to update.
3. Click the options menu icon:

4. Click Update, then either drag and drop the file or click the link to select the file from your local file system.

5. Click Submit, then click Save.

Updating a SOAP API

You can update the configuration of an existing SOAP API either by uploading a WSDL file, or by uploading a .zip archive that contains a primary WSDL file together with other WSDL or XSD files that it references.

About this task

You complete this task by using the browser based API Manager UI.

You can also use the API Connect developer toolkit CLI to update a SOAP API; for more information see API development and management commands.

When you initiate the update action, the specified WSDL is parsed to find a service that matches the name of the API that you are updating. If a match is found, the WSDL service is converted into a YAML file that is used to update the API. If no match is found, an error message is displayed.

Only those sections of the API that are affected by the new WSDL are replaced, the other sections are unchanged.

Procedure

To update a SOAP API from a WSDL file or a .zip archive, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the SOAP API that you want to update.
3. Click the options menu icon:

4. Then click Update WSDL, and either drag and drop the file or click the link to select the file from your local file system.
   The format of the WSDL file is validated. If the format is invalid, an error message is displayed.
5. Click Next.
   The services in the selected API are displayed. If no match is found, an error message is displayed.
6. Click Upload.
   The SOAP API is updated from the specified WSDL definition.
7. Click Save to save the updates.
8. If you updated a previously published API, you must publish it again for the change to take effect:
   a. Click the Online/Offline toggle (shown in step 3) to set the API as Offline.
   b. Click the toggle again to set the API back to Online, which publishes the API again.

Related tasks

- Creating an API definition

Renaming an API definition

By renaming an API definition, you change the **`name`** property that, together with the version, is used to uniquely identify the API definition in API Connect. The **`name`** property is initially generated automatically when you first create the API definition, based on the title, but you can later change it if desired.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Click the options menu icon:

4. To rename the API, select Rename.
   Only this version of the API is renamed.
5. Enter the new name, then click Submit.

Note: If you previously added the API to a Product, it will no longer be recognized by that Product. You must open the Product and modify the `apis:` section on the Source tab as appropriate; for example:

```
apis:
  newname1.0.0:
    name: 'newname:1.0.0'
```

Changing an API rate limit

When you activate an API to make it available for testing, as described in Activating an API, no rate limit is applied to restrict calls to the API. However, if desired, you can apply a rate limit to the API, or modify a previously applied rate limit. The rate limit defines the maximum number of calls allowed in a specified time period.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Note:

- For information about rate limits and burst limits in API Connect, see Understanding rate limits for APIs and Plans.
- If you opted to use an automatically generated Product, you can configure a rate limit to control calls to the API. If you selected your own Product, the **Target product rate limit** option is not available; instead, the rate limits that are configured in the selected Product and Plan are applied. for more information, see Defining rate limits for an API operation.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Select Test tab and click Target Configuration.
4. On the Preferences page, locate the Target product rate limit and click Edit.
5. Select Unlimited to allow unrestricted calls to the API, or select Custom to define the required rate limit; use the supplied fields to define the maximum number of calls allowed in a specified time period; for example, 100 calls per 1 minute.
   Note:
   The system clock determines the start time for rate, and burst limits. The intervals are configured as follows:
   - 1 second interval starts at each new second.
   - 1 minute interval starts at the beginning of each minute.
   - 1 hour interval starts at the beginning of each hour.
   - 1 day interval starts at midnight UTC.
   - 1 week interval starts on Thursday at 00:00:00 UTC.
6. Click Choose Rate Limit when done.
7. Click Save Preferences.

Results

You have successfully updated the rate limit period for the API.

Adding an OpenAPI extension to an API

You can extend the OpenAPI specification by adding either a JSON or YAML extension schema to an API. An OpenAPI extension is imported into a Catalog, or to a Space within a Catalog, then added to the API schema.

Before you begin

Import the OpenAPI extension into the Sandbox Catalog, or into any Catalog to which the API that you are adding the extension to will be published; see Importing an OpenAPI extension into a Catalog.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the **`Api-Drafts:Edit`** permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. Click the title of the API that you want to work with.
3. Select the Gateway tab, expand Gateway and portal settings, then click Extensions.
4. Select the OpenAPI extensions that you want to use with this API, then click Save.

Note: The OpenAPI extensions listed are those that have been imported into the Catalog and gateway service defined in the testing preferences for the API; see Importing an OpenAPI extension into a Catalog and Specifying the testing preferences for an API. You will also need to import the OpenAPI extension into any Catalog to which the API will be published.

5. Update the OpenAPI source for the API definition with the values for the fields as defined in your selected OpenAPI extension schema files, as follows:
   a. Click the Source icon </>.
   b. Add a property whose name must begin with `x-` and references the name of the OpenAPI extension that you created. Specify the values of the properties that were defined in the OpenAPI extension YAML file.
      For an example, see Referring to an extension in an API definition
   c. Click Save when done.

Downloading an API definition

You can download the details of your API definitions so that you can store them for later recovery.

Before you begin

To complete this task, you must have created an API definition. For more information, see Creating an API definition.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Drafts:View` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

You can download REST APIs that were created by using Creating a REST proxy API from a target service for example. This download creates a .yaml file that defines the API.

You can download SOAP APIs that were created by using Creating a REST proxy API from an existing WSDL service , or Creating a SOAP proxy API from an existing WSDL service for example. This download creates a .zip file that contains the WSDL definition and the YAML file that defines the API.

You can use the downloaded .yaml and .zip files to re-create your API. For information about creating an API from a .yaml file, see Adding a REST API by importing an OpenAPI definition file. For information about creating an API from a .zip file, see Adding a SOAP API by importing a zip file.

Procedure

To download a .yaml, or .zip file that contains the details of your API, complete the following steps:

1. In the navigation pane, click Develop, then select the APIs tab.
2. Alongside the API version that you want to work with, click the options icon and then click Download.
3. Save the file to the required location.

Results

You downloaded a .yaml, or .zip file with a representation of your API.

Deleting an API definition

You can delete an API definition that is no longer required.

About this task

You can complete this task either by using the API Designer UI application, or by using the browser-based API Manager UI.

API Manager UI only: To complete this task, you must be assigned a role that has the `Api-Drafts:Edit` permission. The pre-supplied Developer role has this permission by default; if you are assigned a custom role it must have this permission. For more information, see Creating custom roles.

Procedure

1. In the navigation pane, click Develop, then select the APIs tab.
2. You can delete an API either from the Develop listing page, or from within the API definition itself.
   a. To delete an API from the Develop listing page, click the options menu icon alongside the required API, and then select Delete.
   b. To delete an API from within the API definition, complete the following steps:
      i. Click the title of the API definition that you want to work with.
      ii. Click the options menu icon:

      iii. To delete just this version of the API, select Delete. To delete all versions of this API, select Delete API.

Note: If a Product was previously generated automatically from the API, by using the Activate API option, that Product will be deleted together with the API; such Products have the title *api_title* auto product.

3. Click Delete to confirm.

Using an options file when importing a WSDL service

When you create an API definition, or add a target WSDL service to an API definition, by importing a .zip file, you can specify additional directives by including an options file in the .zip file.

You can use an options file when importing a .zip file while performing any of the following tasks:

- Creating a REST proxy API; see Creating a REST proxy API from an existing WSDL service.
- Creating a SOAP proxy API; see Creating a SOAP proxy API from an existing WSDL service.
- Adding a target WSDL service to an API definition; see Editing an API definition.

The options file is a YAML file, and must have the file name apiconnect.yaml.

You can include the following fields in the file:

Table 1. Fields that can be included in the apiconnect.yaml file

Field name	Value	Default	Description
`suppressExamples`	`true` or `false`	`false`	Suppress auto-generation of examples.
`wssecurity`	`true` or `false`	`true`	Enable generation of definitions for WS-Security headers.
`implicitHeaderFiles`	Array of XSD file locations		Additional schema files, not referenced in the WSDL, that are used to define additional SOAP headers.
`port`	The `name` attribute for a `wsdl:port` in a `wsdl:service` definition.		Create the API by using the information for the specified port. If the specified port does not exist, or refers to a REST/XML port rather than a SOAP port, the API creation fails. If no `port` field is present in the options file, API Connect creates the API by using the first SOAP port that it finds in the `wsdl:service` definition.

Example

```
suppressExamples: true
wssecurity: false
implicitHeaderFiles:
  - xsdDir/schema1.xsd
  - xsdDir/schema2.xsd
```

Variable references in API Connect

In API Connect you can reference different variables in your API definition.

When defining an API, creating a custom policy, or configuring another policy or logic construct, you can include references to context variables and properties.

Variable references are resolved either when the API is staged in a Product, for static variables that are fixed upon staging, or when the API is called, for variables that can change with each API call.

Types of variables

Context variables
: A context variable is a variable relevant during an API call, for example, the input of the call, the path of the call, or the message during the call. A context variable is one of the variables that makes up that particular context.
Context variables can consist of more than one part, for example, `request.headers`.

: For a list of available context variables, see API Connect context variables.

API properties
: An API property is a variable in an API where its value depends upon the Catalog in which the API is staged or published. By referencing an API property, you can use the same API definition in different Catalogs where there are small differences between the instances of the API between the Catalogs. For example, an assembly could contain an `if` construct that executes its case when a particular Catalog is used, determined from the value of the API property. API properties can also be used to hide a value such as a password by encoding the value.
API properties are referenced by name.

: For a list of API properties, see API properties

: For more information, see Setting API properties (OpenAPI 2.0) or Setting API properties (OpenAPI 3.0).

: Note: Once defined, an API property is read only.

Catalog properties
: A Catalog property is specific to a Catalog. and can be referenced in any of the API definitions in that Catalog. For more information, see Creating and configuring Catalogs.

Notes:

- If you change the value of a Catalog property, any API that references that property must be republished for it use the new value.
- Catalog properties and API properties are not supported with global policies. Therefore, if you use such properties in a global policy, they are not replaced with the values specified in the Catalog or API property definitions.

Methods of referencing variables

You can get, or set, the value for a referenced variable.

- Get the value for a variable in either of the following ways:
  - Through the GatewayScript policy, run the **`apim.getvariable()`** API.
  - API Gateway only Through the GatewayScript policy, use the **`context.get()`** function; for more information, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.
  - Through the XSLT policy, run a stylesheet that uses the **`apim:getVariable`** extension function.
  - In an assembly policy field that supports variable references, use the following syntax:

    `$(variable)`
- Set the value for a variable in either of the following ways:
  - Through the Set Variable policy.
  - Through the GatewayScript policy, use the **`apim.setvariable()`** API.
  - API Gateway only Through the GatewayScript policy, use the **`context.set()`** function; for more information, see Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.
  - Through the XSLT policy, run a stylesheet that uses the **`apim:setVariable`** extension element.

GatewayScript references

When you want to reference a variable in a GatewayScript context, use one of the following methods:

`apim.getvariable(variable)`

where *variable* is the name of the context variable or API property that you want to reference.

`apim.setvariable(variable, value, action)`

where

- *variable* is the name of the context variable or API property that you want to reference.
- *value* is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, use the following code:

  ```
  var contentType = apim.getvariable('request.headers.content-type');
  apim.setvariable(variable, contentType, 'set');
  ```

  This property is required only when **`set`** or **`add`** is specified as the action.
- *action* is the action that you want to apply to the variable. Valid options are:
  - **`set`**
  - **`add`**
  - **`clear`**

  If no option is set, the default option of **`set`** is applied.

Use the **`getvariable`** method to retrieve the value of a context variable or API property, and the **`setvariable`** method to change one.

Some of the situations where you would use this type of reference are:

- GatewayScript policies. -For more information, see GatewayScript.
- **`if`** logic constructs. For more information, see if.
- User-defined policies. For more information, see Authoring policies.

Stylesheet references

You can reference a variable by using functions and elements in an XSLT policy with the following syntax:

`<xsl:variable name="variable_name" select="apim:getVariable(variable)" />`

where *variable* is a literal value, another variable, or a valid XSLT XPath statement.

```
<xsl:call-template name="apim:setVariable">
    <xsl:with-param name="varName" select="variable"/>
    <xsl:with-param name="value" select="value"/>
    <xsl:with-param name="action" select="action"/>
</xsl:call-template>
```

where

- *variable* is the name of the context variable or API property that you want to reference. This can be a literal value, another variable, or a valid XSLT XPath statement.
- *value* is the string value that you want to set the variable to. This can be a literal value, another variable, or a valid XSLT XPath statement. This property is required only when **`set`** or **`add`** is specified as the action.
- *action* is the action that you want to apply to the variable. This can be a literal value, another variable, or a valid XSLT XPath statement. Valid options are:
  - **`set`**
  - **`add`**
  - **`clear`**

  If no option is set, the default option of **`set`** is applied.

The following example sets a named variable to the value of the Content-Type header in a request:

```
<xsl:variable name="contentType" select="apim:getVariable('request.headers.content-type')" />
<xsl:call-template name="apim:setVariable">
```

```
    <xsl:with-param name="varName" select="'variable'"/>
    <xsl:with-param name="value" select="$contentType"/>
    <xsl:with-param name="action" select="'set'"/>
</xsl:call-template>
```

Inline references

In many situations you can make a simpler reference, by using the following syntax:

```
$(variable)
```

where *variable* is the name of the context variable or API property that you want to reference.
Some of the situations where you would use this type of reference are:

- The URL called by an Invoke or Proxy policy. For more information about the policies, see Invoke or Proxy.
- A Map policy. For more information, see Map.

Notes: The map policy can reference the following variables inline:

- Variables that are defined as inputs to the map policy and specified in the from field of a mapping.
- Context variable or API properties, provided that the `x-ibm-gateway-map-resolve-apic-variables` API property is not set to `false`. If an inline reference in a map policy resolves to a context variable or API property, it is immediately replaced by the corresponding value. For more information on the `x-ibm-gateway-map-resolve-apic-variables` API property, see Properties controlling the map policy.

For more information on the use of inline references, and examples, see the following About inline references section.

About inline references

When you use an inline reference for a property value in an assembly policy, the variable reference is replaced with the corresponding string value at run time, before the property is evaluated. For example, consider the following incoming request, which has two headers and two query parameters (a **curl** command is used to illustrate the request):

```
curl --data-binary @request.json \
   -H 'Content-Type: application/json' \
   -H 'X-Environment: test' \
   http://apiserver/org/catalog/petstore/getPetDetails?petid=285&storeid=z03
```

If an `invoke` policy is configured as follows:

```
invoke:
   target-url: https://backend/GetPetInfo/$(request.parameters.storeid)/$(request.parameters.petid)
```

then the value of the `target-url` property is evaluated as `https://backend/GetPetInfo/z03/285`, and this is therefore the URL to which the `invoke` policy sends its request.

DataPower Gateway (v5 compatible) only You can also use an inline reference in the `condition` property of a `switch` policy. Consider the following example:

```
- switch:
    case:
        - condition: "$(request.headers.X-Environment)" == "production"
          execute:
              - invoke:
                  http://www.finance.com/base/stockquote
        - condition: "$(request.headers.X-Environment)" == "test"
          execute:
              - invoke:
                  http://testserver1.finance.com/stockquote
```

Using the incoming request referred to previously, the value of the `X-Environment` header is `"test"`. The inline references are first evaluated, then the conditions are evaluated as JavaScript. Therefore, the first condition is evaluated as `"test" == "production"`, returning `false`, and the second condition is evaluated as `"test" == "test"`, returning `true`, so the `invoke` policy sends its request to `http://testserver1.finance.com/stockquote`.
Important: This example, which encloses the inline references inside double quotes, assumes that the API is deployed to the DataPower API Gateway. If you deploy the API to the DataPower Gateway (v5 compatible), then the double quotes are added implicitly when the inline references are evaluated, and you must therefore omit them from the `condition` property; the two conditions in this example would therefore be

```
condition: $(request.headers.X-Environment) == "production"
```

and

```
condition: $(request.headers.X-Environment) == "test"
```

However, as an alternative to using an inline reference in a `condition`, you can instead use pure JavaScript, as follows:

```
- switch:
    case:
        - condition: request.headers["X-Environment"] == "production"
          execute:
              - invoke:
                  http://www.finance.com/base/stockquote
        - condition: request.headers["X-Environment"] == "test"
          execute:
              - invoke:
                  http://testserver1.finance.com/stockquote
```

in which case the policy configuration will work correctly as-is in both types of gateway.
For more information on the types of gateway, see API Connect gateway types.

In addition to single strings, you can use an inline reference for a complete object. Consider the following example, which uses an inline reference in a `set-variable` policy:

```
- set-variable:
    actions:
```

```
        - set: saved.reqHdrs
           value: $(request.headers)
           type: string
```

Here, the `request.headers` structured JSON object is substituted with its corresponding string representation, and a variable named `reqHdrs` is therefore created, under the `saved` object, with a string value of `{"Content-Type":"application/json","X-Environment":"test",...}`. However, if you are using the DataPower API Gateway, you can specify `type: any`, in which case the `set-variable` policy copies the value as-is, and `saved.reqHdrs` is created as a JSON object rather than a string:

```
- set-variable:
    actions:
        - set: saved.reqHdrs
           value: $(request.headers)
           type: any
```

You can reference a property in a JSON or XML request directly by name, by using the following syntax:

`$(request.body.property_name)`

For example, if the request contains `{ "account-number": 123 }` or `<account-number>123</account-number>` you can retrieve the value `123` by using the following inline reference:

`$(request.body.account-number)`

If the property value is within a nested property structure, you can reference it by concatenating the property names. For example, if the request contains `{ "account": { "balance": 123 } }` or `<account><balance>123</balance></account>` you can retrieve the value `123` by using the following inline reference:

`$(request.body.account.balance)`

Similarly, you can reference a property in a JSON or XML response by using the following syntax:

`$(message.body.property_name)`

Restriction: If you are using the DataPower API Gateway, you can reference properties in this way only if the format of the request or response is JSON; the mechanism is not supported with XML request or response formats. If the you are using the DataPower Gateway (v5 compatible) the mechanism is supported with both JSON and XML formats.

API properties

Properties are used by the gateway to control behavior of certain policies. Typically, you provide properties, but the policy can also provide properties settings.

In IBM® API Connect, you can create API properties that consist of Catalog-specific values to eliminate the need for source code modifications. You can then reference the properties elsewhere in your API definition.

Pre-supplied API properties

Pre-supplied API properties for various policies are shown in the tables.

A list of invoke related API properties that control the behavior of the invoke policy.

Table 1. Properties controlling the invoke policy

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-decode-request-params	No	If set to a value of `true`, any request parameters that are referenced by a variable definition on an invoke target-url are URL-decoded. The default behavior is to not decode any parameters, thereby sending them to the target URL without alteration.	Boolean

DataPower Gateway (v5 compatible) only
x-ibm-gateway-invoke-suppress-clientid
	No	When set with a value of `true`, or not specified, the X-IBM-Client-Id HTTP header (if specified on the API request) is suppressed from being sent to the invoke target URL. When set with a value of `false`, the X-IBM-Client-Id HTTP header is no longer suppressed from being sent to the invoke target URL.
		This property is supported only by the DataPower® Gateway (v5 compatible). If you are using the DataPower API Gateway then to achieve the same functionality add a `header-control` property to the `invoke` policy configuration in the OpenAPI definition for your API, as in the following examples.
		
		Suppress the `X-Client-ID` header as follows:
		`- invoke:`
		`  target-url: http://myhostname/mypath`
		`  header-control:`
		`  type: blacklist`
		`  values:`
		`  - ^X-Client-ID$`
		
		Suppress the `userId` query parameter as follows:
		`- invoke:`
		`  target-url: http://myhostname/mypath`
		`  parameter-control:`
		`  type: blacklist`
		`  values:`
		`  - ^userId$`
			Boolean

DataPower Gateway (v5 compatible) only x-ibm-gateway-optimize-invoke	No	If set to `false`, prevents the replacement of the last invoke in a policy with proxy. Any value other than `false` (case insensitive) will result in the last invoke in a policy possibly being replaced by proxy when the API is executed in the gateway.	Boolean

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-queryparam-encode-plus-char	No	If set to a value of **true**, all "+" characters in the query parameter values of the target-url of the Invoke and Proxy policies are encoded to "%2F". The default value is **false**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-api-enforce-response-limits	No	If set to a value of **true**, allows the JSON parser to be enforced on the response rule. If the response body size is higher than the JSON parser limit set in the DataPower domain, a status code of 500 is returned. Note: The x-ibm-gateway-api-enforce-response-limits property is supported by the DataPower Gateway (v5 compatible) but not by the DataPower API Gateway. However, if you are using the DataPower API Gateway, consider using a Parse policy in your API assembly to enforce these limits. For information on the different types of gateway, see API Connect gateway types.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-invoke-emulate-v4-soap-error	No	IBM API Management Version 4.0 initiates a DataPower error when a SOAP fault is returned from a web service. IBM API Connect provides a mechanism to catch SOAP errors and does not initiate a DataPower error. For compatibility with APIs developed in IBM API Management Version 4.0, set this property to **true** only in the case where a gateway extension is expecting to handle a SOAP error in a post error rule. The default value is **false**. Note: This property is deprecated in favor of x-ibm-gateway-invoke-emulate-v4-invoke-error.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-invoke-keep-payload	No	If set to a value of **true**, the invoke policy sends a payload on an HTTP DELETE method. This property is available for use with IBM DataPower Gateway version 7.7.1.1 and later. The default value is **false**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-invoke-emulate-v4-invoke-error	No	IBM API Management Version 4.0 initiates a DataPower error when a backend server error is returned, either a SOAP fault returned from a web service or a JSON or XML (non-SOAP) error from a restful service. IBM API Connect provides a mechanism to catch SOAP errors and operation errors and does not initiate a DataPower error when they occur. If no catch policy is configured, a generic error message is generated. For compatibility with APIs developed in IBM API Management Version 4.0, set this property to **true** only in the case where a gateway extension is expecting to handle a backend server error in a gateway extension post error rule or if the client of the API is expecting the backend server error to be returned. The default value is **false**.	Boolean

A list of map-related API properties that control the behavior of the map policy.

Table 2. Properties controlling the map policy

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-array-first-element-value	No	In IBM API Management Version 4.0, if a mapping source value is from an array then only the first value is output. In API Connect, the default behavior is to return an array of all array element values. To maintain compatibility with IBM API Management Version 4.0, set this API property to **true** to only return the first array element value.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-resolve-apic-variables	No	By default, any API Connect variable that is found in the map configuration is resolved. For example, **$(request.headers.content-type)** resolves to the request's content type header. Because searching for variables in every map property can be CPU intensive, you can choose not to resolve variables by setting this API property to `false`. If this property is not configured or is set to any other value, the existing behavior to search for these variables continues. Note that variable usage within a map value JavaScript snippet is not changed provided that the variables that are referenced come from a configured map input.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-create-empty-array	No	This property controls how the map policy handles the output of an empty array; it can have the following values: • **all**: Output all empty arrays, including empty children arrays. This is the default value if the property is not configured or has an invalid value. • **parent**: Output only the current property's empty array value. Children map actions of this property are not attempted. • **none**: Prevent any empty output array values from being produced.	String
DataPower Gateway (v5 compatible) only x-ibm-gateway-optimize-schema-definition	No	Set the value of this property to **true** to provide a performance improvement to the map policy when a very complex schema definition is referenced by a policy output definition; for example, some very complex schemas that are generated by importing a very complex WSDL schema. The map policy builds a schema from an API definition when a referenced definition is provided as the value of the schema. If the schema does not have references that generate a circular reference, setting this property to **true** might provide a performance benefit while generating the same schema as would otherwise have been generated. However, in cases where the schema is very complex, with many potentially circular references, the generated schema could be different because the enhanced schema handling processes circular references differently. In such cases therefore, you should examine the resulting output to determine if the performance benefit gained is not at the expense of a change in the map policy output. The default value of this property, is **false**, maintaining the existing behavior and performance.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-null-value	No	Set the value of this API property to **true** to allow a property from a map policy's input data with a value of **null** to be mapped to the output document. By default, a property from a map policy's input data with a value of **null** is not mapped to the output document.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-resolve-xmlinput-datatypes	No	XML input elements with numeric or boolean data have no metadata to indicate whether this data should be mapped as a string value or as the specific data type. If you set the value of this property to **false**, XML input elements are always mapped as a string. If you set the value to **true**, numeric or boolean XML input elements are mapped as the corresponding data type from the input schema. The default value is **false**.	Boolean

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-map-xml-empty-element	No	This property controls how the map policy handles XML input empty elements and impacts JSON output when the input document is XML; it can have the following values: • **`string`**: The value for an empty XML element is considered to be an empty string. This is the default value if the property is not configured or has an invalid value. • **`null`**: The value for an empty XML element is considered to be null. A mapping of this element to a JSON output property does not occur unless the API property x-ibm-gateway-map-null-value is also specified with a value of **`true`**. • **`none`**: The empty XML element is ignored. • **`string-badgerfish`**: The value for an empty XML element is considered to be an empty string. The empty string value will be placed into a JSON badgerfish value property. • **`null-badgerfish`**: The value for an empty XML element is considered to be null. The null value will be placed into a JSON badgerfish value property. A mapping of this element to a JSON output property does not occur unless the API property **`x-ibm-gateway-map-null-value`** is also specified with a value of **`true`**.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-schema-definition-reference-limit	No	Set the value of this property to an integer value that specifies the maximum allowed number of iterations of a circular schema definition. The default value is 1, which means that circular schema definitions are not followed. The maximum possible value is 5. If you specify a value greater than 5, a value of 5 is assumed. If you specify a non-numeric value, a value of 1 is assumed.	String

DataPower Gateway (v5 compatible) only
x-ibm-gateway-map-emulate-v4-default-required-properties
	No	Set this property to true to have default values generated in the output for required properties that are either not mapped, or for which there is no input data present, in the following specific cases:
		• An array consists of objects that contain one or more required properties.
		• An object which is optional has one or more child properties that are required.
		By default, these required properties are not present in the output. If you set the **`x-ibm-gateway-map-emulate-v4-default-required-properties`** API property to **`true`**, these required properties will be present in the output. If the output schema defines a **`default`** property for the output property then the specified default value is used, otherwise a default value is assigned dependent on the data type, as follows:
		• String: empty string ("")
		• Number: 0
		• Boolean: false
		• Object: empty object
		• Array: empty array
		Example 1
		The input data has the following array of objects:
		`[{"a": "value1"}, {"a": "value2", "b": "value3"}]`
		The output schema defines the output object as having two properties, **`a`** and **`b`**, of which **`b`** is required. The map policy defines the following mappings:
		• **`input.array.a`** to **`output.array.a`**
		• **`input.array.b`** to **`output.array.b`**
		If the **`x-ibm-gateway-map-emulate-v4-default-required-properties`** API property is set to **`true`**, and **`b`** is either not mapped or has no input data present, then **`b`** is assigned a default value of an empty string, and the output is as follows:
		`[{"a": "value1", "b": ""}, {"a": "value2", "b": "value3"}]`
		Example 2
		The output schema defines the following structure:
		`{"a" : {"b" : {"c" : "value1", "d" : "value2"} } }`
		Property **`b`** is optional but property **`d`** within **`b`** is required.
		The map policy defines a mapping to **`output.a.b.c`**.
		If the **`x-ibm-gateway-map-emulate-v4-default-required-properties`** API property is set to **`true`**, and **`d`** is not mapped, then **`d`** is assigned a default value of an empty string, and the output is as follows:
		`{"a" : {"b" : {"c" : "value1", "d" : ""} } }`
		If the **`x-ibm-gateway-map-emulate-v4-default-required-properties`** API property is not specified or does not have a value of **`true`**, these required properties are **not** created in the output with their default values.
			Boolean

DataPower Gateway (v5 compatible) only x-ibm-gateway-map-post-process-json-output	No	Set the value of this property to **`true`** to enable post processing of mapped JSON output. The post processing of JSON output will use the output schema to ensure that property values are of the same data type as that defined in the schema. It will also normalize output property values that have a Badgerfish JSON syntax due to object mapping of an XML input. Set the value to **`false`** for no post processing of mapped JSON output. The default value is **`false`**.	Boolean

Property	Required	Description	Data type

DataPower Gateway (v5 compatible) only
x-ibm-gateway-map-emulate-v4-empty-json-object
	No	If a mapping fails because its input is not present and there is no default mapping configured, the default behavior is to not to make any change to the output mapping. Set the value of this property to **true** to create an empty object for the parent of the target mapping, emulating the behavior of IBM API Management Version 4.0.
		
		Example
		The map policy defines a mapping to **output.a.b.c**.
		If input data is present, the output is as follows:
		
		`{ "a": { "b": { "c": "inputvalue" } } }`
		
		If there is no input data, and the **x-ibm-gateway-map-emulate-v4-empty-json-object** API property is set to **true**, the output is as follows:
		
		`{ "a": { "b": { } } }`
		
		Properties **a** and **b** are created but the value of **b** is an empty object.
		The default value is **false**.
			Boolean

DataPower Gateway (v5 compatible) only A list of proxy-related API properties that control the behavior of the proxy policy.

Table 3. Properties controlling the proxy policy

Property	Required	Description	Data type

x-ibm-gateway-proxy-suppress-clientid	No	A setting of `false` activates the injection of the X-IBM-Client-Id HTTP header (if it is specified on the API request), or the **client_id** query parameter in the request URL, to the proxy target-url. If not specified, or set with a value of `true`, suppresses the sending of this parameter to the proxy target-url.
		This property is supported only by the DataPower Gateway (v5 compatible). If you are using the DataPower API Gateway then to achieve the same functionality add a **header-control** property to the **invoke** policy configuration in the OpenAPI definition for your API, as in the following examples.
		
		Suppress the **X-Client-ID** header as follows:
		
		`- proxy: target-url: http://myhostname/mypath header-control: type: blacklist values: - ^X-Client-ID$`
		
		Suppress the **userId** query parameter as follows:
		
		`- proxy: target-url: http://myhostname/mypath parameter-control: type: blacklist values: - ^userId$`
			Boolean

x-ibm-gateway-optimize-invoke	No	If set to `false`, prevents the replacement of the last invoke in a policy with proxy. Any value other than `false` (case insensitive) will result in the last invoke in a policy possibly being replaced by proxy when the API is executed in the gateway.	Boolean
x-ibm-gateway-queryparam-encode-plus-char	No	If set to a value of **true**, all "+" characters in the query parameter values of the target-url of Invoke and Proxy policies are encoded to "%2F". The default value is **false**.	Boolean
x-ibm-gateway-api-enforce-response-limits	No	If set to a value of **true**, allows the JSON parser to be enforced on the response rule. If the response body size is higher than the JSON parser limit set in the DataPower domain, a status code of 500 is returned.	Boolean

A list of API properties that control the behavior of the rate limit policy.

Table 4. Properties controlling the rate limit policy

Property	Required	Description	Data type
x-ibm-gateway-emulate-v4-plan-rate-limit	No	By default in IBM API Connect Version 10, if you configure a rate limit only for a Plan and not for the API operations within the Plan then a single rate limit threshold is set for the API as a whole, regardless of which operation in the API is requested. This behavior differs from IBM API Management Version 4.0 where the rate limit is set **individually** for **each** operation in the API. To change the Version 10 behavior to emulate the Version 4.0 behavior, set this API property to a value of **true**.	Boolean

A list of API properties that control the behavior of multiple policies.

Table 5. Properties controlling multiple policies

Property	Required	Description	Data type

Property	Required	Description	Data type
DataPower Gateway (v5 compatible) only x-ibm-gateway-sourcecode-resolve-apic-variables	No	If set to **true**, API Connect variable references are resolved. Set to **false** if you want the policy to ignore API Connect variable references. The default value is **true**. This property applies to the following policies: • Map • GatewayScript • XSLT • if • switch Note: This property setting is overridden by the x-ibm-gateway-map-resolve-apic-variables API property setting for the Map policy.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-api-json-parse-error-handling	No	If an API request or response payload includes valid JSON content that contains characters that cannot be represented in the JSONX XML internal syntax that is used by the DataPower Gateway, set this property to **escape-unicode** to allow the payload to be accepted without parsing errors. If this property is not configured or is set to any other value, the payload is rejected as invalid JSON. This property applies to the API request payload, and to the API response payload when **x-ibm-gateway-api-enforce-response-limits** is enabled.	String
DataPower Gateway (v5 compatible) only x-ibm-gateway-framework-preserve-escaped-reverse-solidus	No	By default, the string **** in a policy property is converted to a single **** character. Set this property to **true** to preserve the string ****.	Boolean
DataPower Gateway (v5 compatible) only x-ibm-gateway-inspect-request-headers	No	Causes an inspection of the HTTP headers in the API request to check for characters in the header values that are illegal XML characters; it can have the following values: • **default**: There is no inspection for these characters in the header values. If one is present, the API request fails with an HTTP 500 Internal Server Error. • **sanitize**: Any illegal XML characters in header values are replaced with a **?** character. The API processing will continue. Any API that attempts to read **request.headers.<headername>** will see the **?** character in the value. However, the original protocol headers representing **message.headers** will still have the original character, which will be sent to an invoke or proxy backend server. • **bad-request**: There will be an inspection for these characters in the header values. If one is present, the API request fails with an HTTP 400 Bad Request. The default value is **default**.	Boolean

API policies and logic constructs

Policies and logic constructs are pieces of configuration that control a specific aspect of processing in the Gateway server during the handling of an API invocation at run time.

Policies are the building blocks of assembly flows, and they provide the means to configure capability, such as security, logging, routing of requests to target services, and transformation of data from one format to another. Policies can be configured in the context of an API or in the context of a Plan.

Logic constructs behave in a similar way to policies, but they affect how and which parts of the assembly are implemented without modifying the data flow of the assembly.

IBM® API Connect provides the following ways that you can create, configure, and apply policies and logic constructs:

Policies associated with a Plan
: A Plan provides a mechanism for grouping API operations or subsets of operations from one or more APIs. You can set rate limiting policies on a Plan to specify how many requests an application is allowed to make during a specified time interval. You can also configure a policy for each operation that is included in a Plan. For more information, see Working with Products.

Registration policies
: This section provides details about the out-of-the-box (OOTB) policies that are automatically deployed to the DataPower® API Gateway. It outlines the policies included in the registration process and is updated as needed to reflect changes in each release.

Built-in policies
: A built-in policy enables you to apply a pre-configured policy statement to an assembly to control processing capabilities in the Gateway server. Built-in policies are applied by using the API Designer assembly editor to add a built-in policy to your assembly and to configure the properties for that policy. For more information, see Built-in policies.
Note: You can also apply built-in policies to your APIs by adding an **assembly** extension to your OpenAPI definition file. For more information, see IBM extensions to the OpenAPI specification.

Logic constructs
: A logic construct enables you to control the flow of data through your assembly during an API call. Like policies, logic constructs are applied to an API by using the API Designer assembly editor to add a logic construct to your assembly and to configure the behavior of the construct. For more information, see Logic Constructs.
Note: You can also apply logic constructs to your APIs by adding an **assembly** extension to your OpenAPI definition file. For more information, see IBM extensions to the OpenAPI specification.

User-defined policies
: A user-defined policy enables you to create your own policies to control extra processing features in the Gateway server, such as security, or routing of requests. User-defined policies are created outside of API Connect and then imported into one or more Catalogs, so they can be applied to an operation in the same way as built-in policies. For more information, see Authoring policies.

- **Built-in policies**
  IBM API Connect includes a number of built-in policies that you can use to apply preconfigured policy statements to an operation to control an aspect of processing

in the Gateway server when an API is invoked.

- **Logic Constructs**
  IBM API Connect includes a number of logic constructs that you can use to apply preconfigured logic to an assembly to control the flow of data through your assembly when the API is called.
- **Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway**
  In the code for GatewayScript and XSLT policies in your API assemblies, you can use API context variables to work with the messages that are generated when an API is called.
- **User-defined policies**
  Make a user-defined policy available to a Catalog, and apply that policy to a REST or SOAP API.

- execute

Built-in policies

IBM® API Connect includes a number of built-in policies that you can use to apply preconfigured policy statements to an operation to control an aspect of processing in the Gateway server when an API is invoked.

Note: Although some built-in policies can be used with both the DataPower® Gateway (v5 compatible) and the DataPower API Gateway, some policies are restricted to a particular Gateway. The following icons indicate which Gateway each policy can be used with:

- 

Indicates that the policy can be run on the DataPower Gateway (v5 compatible).
- 

Indicates that the policy can be run on the DataPower API Gateway.

For details of the two types of gateway, see API Connect gateway types.

Built-in policies are configured in the context of an API. You can use the API Designer assembly editor to add a built-in policy to an API and to configure the properties for that policy.

You can also add built-in policies to an API by creating an OpenAPI definition file. For more information, see Creating an OpenAPI definition file.

The following table shows the list of built-in policies that are available. The table contains links to configuration information for both the built-in policy definitions, and the OpenAPI policy definitions. The policies are the same, but they are created in different ways.

Table 1. Built-in policies

Built-in policy	OpenAPI policy	Description	DataPower Gateway	API Gateway
Activity Log	activity-log	Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity. Note: The Activity Log policy is not supported in the assembly for an API whose gateway type is DataPower API Gateway. Instead, you configure activity logging in the API design settings. For details, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).	✓	✓ Functionality provided in the API design; see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0)
Client Security	client-security	Provides a range of options for authenticating client access to your APIs, extending the capabilities of the OpenAPI specification.	✗	✓
Extract	extract	Use the Extract policy to extract and transform data from fields in your API.	✗	✓
GatewayScript	gatewayscript	Use the gatewayscript policy to execute a specified DataPower GatewayScript program.	✓	✓
Generate JWT	jwt-generate	Use the Generate JWT security policy in IBM API Connect to generate a JSON Web Token (JWT).	✓	✓
GraphQL Cost Analysis	graphql-cost-analysis	Use the GraphQL Cost Analysis policy to return a cost analysis of a target query.	✗	✓
GraphQL Execute	graphql-execute	Use the GraphQL Execute policy to execute a GraphQL query by using sub-queries.	✗	✓
GraphQL Introspect	graphql-introspect	Use the GraphQL Introspect policy to introspect a GraphQL schema.	✗	✓
if	if	Use the if policy to apply a section of the assembly when a condition is fulfilled.	✓	✓ Functionality provided by switch
Invoke	invoke	Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.	✓	✓
JSON to XML	json-to-xml	Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.	✓	✓
Log	log	Use the Log policy to customize or override the default activity logging configuration for an API.	✗	✓
Map	map	Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.	✓	✓
OAuth	oauth	Use the OAuth policy to policy to perform OAuth processing based on defined OAuth provider settings.	✗	✓

Built-in policy	OpenAPI policy	Description	DataPower Gateway	API Gateway
operation-switch	operation-switch	Use the operation-switch policy to apply a section of the assembly to a specific operation.	✓	✓
Parse	parse	Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.	✗	✓
Proxy	proxy	Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the `message.body` and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.	✓	✓ Functionality provided by Invoke
Rate Limit	ratelimit	Use the Rate Limit policy to apply one or more rate or burst limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls that an application can make to an API in a specified time period.	✗	✓
Rate Limit Info	ratelimitinfo	Use the Rate Limit Info policy to return information about your rate limits.	✗	✓
Redaction Redaction - DataPower API Gateway Redaction - DataPower Gateway (v5 compatible)	redact - DataPower API Gateway redact - DataPower Gateway (v5 compatible)	Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.	✓	✓
Set Variable	set-variable	Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.	✓	✓
switch	switch	Use the switch policy to execute one of a number of sections of the assembly based on which specified condition is fulfilled.	✓	✓
throw	throw	Use the throw policy to throw an error when it is reached during the execution of an assembly flow.	✓	✓
User Security	user-security	Use the user-security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.	✗	✓
Validate Validate - DataPower API Gateway Validate - DataPower Gateway (v5 compatible)	validate - DataPower API Gateway validate - DataPower Gateway (v5 compatible)	Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.	✓	✓
Validate JWT	jwt-validate	Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.	✓	✓
Validate Username Token	validate-usernametoken	Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.	✓	✗
XML to JSON	xml-to-json	Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).	✓	✓
XSLT	xslt	Use the XSLT policy to apply an XSLT transform to the payload of the API definition.	✓	✓

Including elements in your OpenAPI 2.0 API assembly, Including elements in your OpenAPI 3.0 API assembly

- **Activity Log**
  Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.
- **Client Security**
  The Client Security policy can be used to extend client authentication access for your APIs.
- **Extract**
  Use the Extract policy to extract and transform data from fields in the API context.
- **GatewayScript**
  Use the gatewayscript policy to execute a specified DataPower GatewayScript program.
- **Gemini invoke**
  Use the Gemini invoke policy to invoke Gemini operations.
- **Generate JWT**
  Use the Generate JWT security policy in IBM API Connect to generate a JSON Web Token (JWT).
- **GraphQL Cost Analysis**
  Use the GraphQL Cost Analysis policy to return a cost analysis of a target query.
- **GraphQL Execute**
  Use the GraphQL Execute policy to execute a GraphQL query by using sub-queries.
- **GraphQL Introspect**
  Use the GraphQL Introspect policy to introspect a GraphQL schema.
- **IBM Cloud Authentication**
  Use the IBM Cloud Authentication policy to authenticate with IBM Cloud and obtain an API key that can be used when sending requests to watsonx.ai.
- **Invoke**
  Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.
- **JSON to XML**
  Use the JSON to XML policy to convert the context payload of your API from the JavaScript Object Notation (JSON) format to the extensible markup language (XML) format.

- **Lambda**
  Use the Lambda policy to directly trigger AWS Lambda functions from API without using the Amazon API Gateway.
- **Log**
  Use the Log policy to customize or override the default activity logging configuration for an API.
- **Map**
  Use the Map policy to apply transformations to your assembly flow and specify relationships between variables.
- **OAuth**
  An OAuth policy performs the requested OAuth processing based on the defined OAuth provider settings.
- **openai invoke**
  Use the OpenAI invoke policy to invoke OpenAI operations.
- **Parse**
  Use the Parse policy to control the parsing of an input document. When the input document is a JSON string, the string is parsed instead of copied over.
- **Proxy**
  Apply the Proxy policy to invoke another API within your assembly, particularly if the separate API contains a large payload. The response from the backend is stored in the `message.body` and in the response object variable if it is defined. Only one policy is permitted to be run per unique assembly flow.
- **Rate Limit**
  Use the Rate Limit policy to apply one or more rate, burst, or count limits at any point in your API assembly flow. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.
- **Rate Limit Info**
  Use the Rate Limit Info policy to return information about rate limits, burst limits, and count limits. Rate and burst limits restrict the number of calls made to an API in a specified time period, while count limits impose a strict limit on the total number of calls.
- **Redaction - DataPower API Gateway**
  Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.
- **Redaction - DataPower Gateway (v5 compatible)**
  Use the Redaction policy to completely remove or to redact specified fields from the Request body, the Response body, and the activity logs. You might find this policy useful for removing or blocking out sensitive data (for example, credit card details) for legal, security, or other reasons.
- **Set Variable**
  Use the Set Variable policy to set the value of a runtime variable, or to clear a runtime variable, or to add a header variable.
- **Token Mediation**
  The Token Mediation policy acts as a mediator for OAuth tokens by caching the token and exchanging it for a session cookie via a set-cookie header. It enables clients to retrieve the cached token from policy or have the policy set the HTTP Authorization header for OAuth resource access.
- **User Security**
  Use the User Security policy to extract a user's credentials, authenticate those credentials, and obtain authorization from the user.
- **Validate - DataPower API Gateway**
  Use the Validate policy to validate the payload in an assembly flow against a schema.
- **Validate - DataPower Gateway (v5 compatible)**
  Use the Validate policy to validate the payload in an assembly flow against a JSON or an XML schema.
- **Validate JWT**
  Use the Validate JWT security policy to enable the validation of a JSON Web Token (JWT) in a request before allowing access to the APIs.
- **Validate Username Token**
  Use the Validate Username Token policy to validate a Web Services Security (WS-Security) UsernameToken in a SOAP payload before allowing access to the protected resource.
- **watsonx.ai invoke**
  Use the watsonx.ai invoke policy to invoke watsonx.ai operations.
- **Websocket Upgrade**
  Use the Websocket Upgrade policy to process API requests and responses through a WebSocket connection.
- **XML to JSON**
  Use the XML to JSON policy to convert the context payload of your API from the extensible markup language (XML) format to JavaScript Object Notation (JSON).
- **XSLT**
  Use the XSLT policy to apply an XSLT transform to the payload of the API definition.

Activity Log

Use the Activity Log policy to configure your logging preferences for the API activity that is stored in IBM® API Connect analytics. The preferences that you specify will override the default settings for collecting and storing details of the API activity.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see activity-log.

Note that if you are using the DataPower API Gateway, you can configure your logging preferences by using the API design editor. For more information, see Configuring activity logging (OpenAPI 2.0) or Configuring activity logging (OpenAPI 3.0).

About

An API event record exists for each API execution event in the Gateway server. By default, the content type that is collected and stored in API event records is `activity` for when API execution completes successfully, and `payload` for when API execution completes with an error code. Apply the Activity Log policy to your assembly to change the type of content to log in these API event records. For more information about API event records, see API event record field reference.
Note: If payload logging is enabled, for the gateway to capture payloads buffering must also be enabled. Enable buffering as follows in the API YAML:

```
x-ibm-configuration:
  ...
  activity-log:
    enabled: true
    error-content: payload
    success-content: payload
  ...
  buffering: true
```

Note:
Activity log policies that call for logging of analytics data upon success do not apply for the OAuth provider. The OAuth provider logs analytics data for failure cases, but does not log successful cases.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Activity Log policy properties

Property label	Required	Description	Data type
Title	Yes	A title for the policy is required, but a default value, `activity-log` is provided.	string
Description	No	A description of the policy.	string
Content	Yes	Defines the type of content to be logged when the operation is successful. Valid values: • **`none`**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **`activity`**: Logs invocation only (only the resource URI is recorded). • **`header`**: Logs activity and header. • **`payload`**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **`activity`**.	string
Error content	No	Indicates what content to log if an error occurs. Valid values: • **`none`**: Indicates that no logging occurs. Restriction: This option disables notifications for application developers who use your Developer Portal. • **`activity`**: Logs invocation only (only the resource URI is recorded). • **`header`**: Logs activity and header. • **`payload`**: Logs activity, header, and payload (the original request, if any, and the final response). The default value is **`payload`**.	string

Client Security

The Client Security policy can be used to extend client authentication access for your APIs.

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see client-security.

About

You use the Client Security policy to create an assembly action that's separate from the OpenAPI specification, to allow for more options to authenticate an application. Note that you cannot use the client-security policy to perform rate-limiting enforcement.

In a client security action, you define the following settings.

- Control whether to stop processing if client security fails. When client security fails, stops assembly processing and returns an error.
- Control whether to require the client secret. When required, the secret is compared to the registered secret on the application that is identified by the client ID.
- Define the method to extract client credentials from the request.
  - For all methods except HTTP, use the ID Name and the Secret Name properties to specify the location that contains the ID and the location that contains the secret.
    - When Cookie, specify which cookie.
    - When Context Variable, specify which runtime context variable.

        - When Form, specify the form data.
        - When Header, specify which header.
        - When Query, specify which query parameter.
    - For the HTTP method, use the HTTP Type property to specify the format of the authorization header, which expects the Basic form in the `basic base64_id:secret` format.
- Define the method to authenticate the extracted client credentials. The supported methods are Native (this means by using IBM® API Connect), or by using a specified Third party user registry.
    - If Third party, use the User Registry Name property to specify the user-registry to authenticate the extracted client credentials. The supported registry types are LDAP and authentication URL.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Client Security policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is `client-security`.	string
Description	No	A description of the policy.	string
Stop on Error	Yes	If this setting is enabled, assembly processing stops if client security fails, and an error is returned. The check box is selected by default.	boolean
Secret Required	Yes	If this setting is enabled, the client secret must be sent in the request. The secret is compared to the registered secret on the application that is identified by the client ID. The check box is selected by default.	boolean
Credential Extraction Method	Yes	Select one of the following options to define how the calling application authenticates: • Header: client ID and client secret credentials must be supplied in the request header. • Query: client ID and client secret credentials must be supplied as query parameters in the request URL. • Form: client ID and client secret credentials must be supplied as form data sent in a POST request. • Cookie: client ID and client secret credentials must be supplied in a header called `Cookie`. • HTTP: the calling application must authenticate by using basic authentication. • Context Variable: the credentials that are used for authenticating the client are obtained from context variables that you set in the assembly flow prior to the Client Security policy, by using a GatewayScript policy for example. The names of these context variables are determined by the values that you supply in the ID Name and Secret Name properties of the Client Security policy. The default value is Header.	string
ID Name	Yes, unless the selected value of Credential Extraction Method is HTTP	The name of the parameter whose value specifies the client ID. For all Credential Extraction Method options other than Context Variable and HTTP, the calling application must supply a parameter with this name, in the location defined by the Credential Extraction Method option. For the Context Variable option, this property specifies the name of a context variable. This property does not apply if the Credential Extraction Method is HTTP.	string
Secret Name	Yes, if Secret Required is enabled and the selected value of Credential Extraction Method is other than HTTP	The name of the parameter whose value specifies the client secret. For all Credential Extraction Method options other than Context Variable and HTTP, the calling application must supply a parameter with this name, in the location defined by the Credential Extraction Method option. For the Context Variable option, this property specifies the name of a context variable. This property does not apply if the Credential Extraction Method is HTTP.	string
HTTP Type	Yes, if the selected value of Credential Extraction Method is HTTP	The authentication type. Currently, the only available option is Basic.	
Authenticate Client Method	Yes	Select one of the following options: • Native: only client ID and client secret are used to authenticate the client. If the selected value of Credential Extraction Method is HTTP then the calling application must supply the client ID for the user name, and the client secret for the password. • Third party: a user registry is used to authenticate the client. If the selected value of Credential Extraction Method is other than HTTP then the calling application must supply the user name for the client ID, and the password for the client secret. The default value is Native.	string
User Registry Name	Yes, if the selected value of Authenticate Client Method is Third party	Select the user registry that will be used to authenticate the client. The supported registry types are LDAP and authentication URL.	string

API Gateway only

Extract

Use the Extract policy to extract and transform data from fields in the API context.

Before you begin

Table 1. Gateways that support this policy and the corresponding policy versions

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly editor. For details about how to configure the policy in your OpenAPI source, see extract.

About this task

The Extract policy specifies the data source that contains the content to transform, the fields that contain the content, and expressions that define how to transform the content. You use a subset of JSONata notation to specify the fields to extract and transform. For more information, see Constructing JSONata expressions to extract and transform data.

The input to the Extract policy must be parsed data. One way to produce parsed data is to add a Parse policy before the Extract policy in your assembly.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.
2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Extract policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 2. Extract policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **extract**.	string
Description	No	A description of the policy.	string
Root	Yes	The data source that contains the content to transform. The default value is **message.body**.	string
Capture	Yes	The path expression that identifies the field. The default setting is **$**, which indicates the entire input.	string
Transform	Yes	The expression that defines how to transform the content.	string

6. Specify a version for the policy by clicking the Source icon </>, and completing the **version** section of the policy YAML. For example:

```
execute:
  - extract:
      version: 2.0.0
      title: extract
...
```

   You must specify a version for the policy that is compatible with the gateway that you are using. When the API is published, if the version is incompatible with the gateway, a validation error is thrown that specifies the available versions.
7. Click Save.

Example

Transform the contents of the **account** field to include only the last 4 characters.

```
- extract:
    version: 2.0.0
    title: extract
    root: message.body
    extracts:
      - capture: $.members.policy.**.account
        transform: $substring($,-4)
    description: Include only the last 4 characters of the account field.
```

- **Constructing JSONata expressions to extract and transform data**
  To extract and transform data from fields in the API context when using the Extract policy with the DataPower API Gateway, you supply a JSONata expression that defines the fields to extract and transform.

API Gateway only

Constructing JSONata expressions to extract and transform data

To extract and transform data from fields in the API context when using the Extract policy with the DataPower® API Gateway, you supply a JSONata expression that defines the fields to extract and transform.

JSONata support in API Connect

API Connect supports v2.0 of the JSONata specification, with the following limitations:

- If you use a JSONata expression to extract or redact fields, soft linked copies of the field are also affected by the Extract or Redaction policy, even if the fields exist in different locations.

- API Connect does not support higher order JSONata functions (functions that process other functions).
- If a JSONata function supported by API Connect calls a higher order function as an argument, that argument is not supported (due to the lack of support for higher order functions).
- The following JSONata v2.0 functions are not supported:
  - `$eval()`
  - `$sift()`
  - `$each()`
  - `$error()`
  - `$assert()`
  - `$fromMillis()` is supported with the following restrictions:
    - The `$fromMillis()` parameter supports numbers in the range -5364662400000 - 2903299199000.
      - A value less than -5364662400000 uses -5364662400000. In other words, reports the timestamp as 1800-01-01T00:00:00Z.
      - A value greater than 2903299199000 uses 2903299199000. In other words, reports the timestamp as 2261-12-31T23:59:59Z.
- `$now()` is supported with the following restrictions:
  - The following component specifiers are not supported:
    - `W` = Week in year
    - `w` = Week in month
    - `X` = ISO week-numbering year
    - `x` = ISO week-numbering month
  - Representing numbers as words are not supported, so the following presentation modifiers are not supported:
    - `W` = Uppercase word (for example: [YW] => TWO THOUSAND AND TWENTY-FOUR)
    - `w` = Lowercase word (for example: [Yw] => two thousand and twenty-four)
    - `Ww` = Title case word (for example: [YWw] => Two Thousand and Twenty-Four)
  - Error messages are generic.

Table 1 lists the functional extensions that you can use with standard JSONata notation. Each extension corresponds to a part of the API context.

Table 1. Functional extensions to JSONata

Extension	Variable	Description

`$apiCtx()`	Generic access to an API context	The `$apiCtx()` extension gives generic access to an API context.
		• Sample transform field in an extract action:
		`"$apiCtx().request.uri"`
		• Sample condition of a case in a switch action:
		`"$apiCtx().request.path = '/simple/apictx-function'"`

`$header(name)`	`message.headers.name`	Message header
`$httpVerb()`	`request.verb`	HTTP method of the request
`$operationID()`	`api.operation.id`	ID of the operation
`$operationPath()`	`api.operation.path`	Path of the operation
`$queryParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keyword is `query`. • `request.parameters.`*`name`*`.values`	Searches for the index of `query` in `request.parameters.`*`name`*`.locations` and returns `request.parameters.`*`name`*`.values[index]`, where `[index]` is the value for `query` in locations. Parameter values are not URL decoded.
`$statusCode()`	`message.status.code`	Status code
`$storageType([arg])`	*`variable`*`.body` You can specify any variable in the API context. When no variable is specified, the default variable `message.body` is used.	Storage type of the message. The supported values are `binary`, `empty`, `graphql`, `json`, `stream`, or `xml`.

`$urlParameter('name')`	• `request.parameters.`*`name`*`.locations` The supported keywords are `path` and `query`
	• `request.parameters.`*`name`*`.values`
		Searches for the index of `path` and `query` in `request.parameters.`*`name`*`.locations` and returns a single array that contains both `path` and `query` values from `request.parameters.`*`name`*`.values`. When the URL contains both path and query parameter values, the array includes the path values first followed by the query values. The values of each parameter type are added in the order that they are received. Parameter values are URL decoded. For example, the following URL contains both path and query parameter values.
		`http://example.com/petstore/cats/adopt?breed=Sphynx&breed=Siamese`
		The `$urlParameter('breed')` URL returns the following array of values.
		`[cats, adopt, Sphynx, Siamese]`
		In this example, the URL includes an API path that is configured as `/petstore/{breed}/{breed}`, where `breed` is configured to be a path parameter of the API path. As a result, `cats` and `adopt` are included in the output.

`$xpath(path, xpathExpression)`	You can specify any writable variable in the API context. The `xpathExpression` must be a literal string.	Allows use of XPath expressions. The following example specifies all price elements in the source. `$xpath($, '//price')`

Table 2 lists the functional extensions that you can use with GraphQL APIs.

Table 2. Functional extensions to JSONata for GraphQL

Extension	Variable	Description
`$gqlActiveOperation([graphql_message])`	`message.body`	Gets the active operation found in the specified GraphQL message. The `operationName` must be the same as the name of the active operation.
`$gqlAlias(graphql_field_node)`	`message.body`	Gets the alias of a GraphQL field node.
`$gqlFragments([graphql_message])`	`message.body`	Gets the fragments found in the specified GraphQL message.
`$gqlName([graphql_node])`	`message.body`	Gets the node name. For operations, the node name is the `operationName`. For fields, fragment definitions, arguments, and other elements, the node name is the name of the element. By default, the `operationName` of `message.body` is retrieved.
`$gqlOperations([graphql_message])`	`message.body`	Gets the operations found in the specified GraphQL message.
`$gqlType([graphql_node])`	`message.body`	The operation type of the active operation is retrieved for Query, Mutation, and Subscription query types.

In addition to the functional extensions, you can use the following operators:

- You can use the `&` (concatenation) navigation operator.

You can use the following JSONata numeric operators:

- `+` (addition)
- `-` (subtraction)
- `*` (multiplication)
- / (division)
- % (modulo)

You can use the following JSONata comparison operators for number values or strings:

- `=`
- `!=`
- `<`
- `>`
- `<=`
- `>=`

You can also use the following operators and expressions.

- Parentheses to convert a sequence into an array, specify operator precedence, or compute complex expressions on a context value.
- Array ranges and predicate expressions.
- Single asterisk (`*`) and double asterisk (`**`) wildcard characters.

The following elements of a GraphQL query can be exposed in JSONata notation using the syntax shown.

- `query`
  The entire GraphQL query including operations and fragments.

- *`operationName`*
  For an anonymous operation, *`operationName`* can be empty.

- *`~fragmentSpreadName`*
- *`on~typeCondition`*
- *`~~fragmentDefinitionName`*

GatewayScript

Use the gatewayscript policy to execute a specified DataPower® GatewayScript program.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see gatewayscript.

About

The gatewayscript policy gives you built-in access to the DataPower Gateway module via variable **`apim`**.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. gatewayscript policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **gatewayscript**.	string
Description	No	A description of the policy.	string

Source	Yes	The GatewayScript source code to execute. For example:
		
		`var message = [ 'Hello', 'World!' ];`
		`console.debug(message.join(' '));`
			string

Examples

The following examples show how the full OpenAPI for the policy looks in the source code.

Example one:

```
gatewayscript:
  title: writes message to DataPower log
  source: console.debug('Hello World!');
```

Example two:

```
gatewayscript:
  title: script written in multiple lines
  source: |
    var message = [ 'Hello', 'World!' ];
    console.debug(message.join(' '));
```

For more code examples, see GatewayScript code examples and, if you are using the DataPower API Gateway, Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

For general information on using GatewayScript, see the following topics in the DataPower product documentation:

- GatewayScript APIs for API management
- Accessing and manipulating a variable in the API context
- OAuth context variables

Errors

The following error can be thrown while the policy is being executed:

- **JavaScriptError** - a generic error that captures all errors that occur during the execution of the policy.
- **GatewayScript code examples**
  Example GatewayScript code snippets to help the creation of a gatewayscript policy.

Related tasks

- Creating a new REST OpenAPI definition

GatewayScript code examples

Example GatewayScript code snippets to help the creation of a gatewayscript policy.

Attention:

- The mechanisms described here for interacting with the API Connect context are intended for v5-compatible gateways and also to provide v5 compatibility for APIs created for the API Gateway. However, if you are writing a GatewayScript policy or user-defined policy for a new API Gateway API, use the mechanisms described in Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway for better performance and long-term support. For API Gateway APIs, the v5-compatibility functions listed here are to be used for v5 migration only.
- The GatewayScript functions that are listed here use the common name **apim** to call the methods. However, you can change the common name to one of your choice by using one or other of the following function calls depending on your gateway type:

  DataPower Gateway (v5 compatible)
  ```
  var name = require('local:///isp/policy/apim.custom.js');   // v5-Compatible Gateway
  ```
  API Gateway
  ```
  var name = require('apim');                                 // DataPower API Gateway
  ```

  where *name* is your chosen name; for example:

  ```
  var apim = require('apim');
  ```

Access the assembly context

The following code snippets show examples of how to access the assembly context.
Example one returns the **request** context:

```
apim.getvariable('request');
```

Example two returns the header named **myheader**:

```
apim.getvariable('request.headers.myheader');
```

Example three shows how to set, add, or clear a context variable, in this case a message header:

```
apim.setvariable('message.headers.name', value, action)
```

where

- *name* is the name of the message header that you want to set, add, or clear.
- *value* is the string value that you want to set the variable to. This can be a literal value, or another variable. For example, to set your named variable to the value of the Content-Type header in a request, you would specify the *value* as `request.headers.content-type`. This property is only required when `set` or `add` is specified as the action.
- *action* is the action that you want to apply to the variable. Valid options are:
  - `set`
  - `add`
  - `clear`

  If no option is set, the default option of `set` is applied.

For a complete list of context variables, see API Gateway context variables, and for more information about how to reference context variables in IBM API Connect see Variable references in API Connect. If you are using the DataPower® API Gateway, see also Using context variables in GatewayScript and XSLT policies with the DataPower API Gateway.

Read input synchronously

The following code snippets show examples of how to read input synchronously by using the `apim.getvariable` function to read data direct from a context. JSON input is returned as a JavaScript object. XML data is returned as a NodeList object (DOM).
Example one returns a synchronous read of the original request body into the variable that is called *json*:

```
var json = apim.getvariable('request.body');
```

Example two returns a synchronous read of the current message into the variable that is called *xml*:

```
var xml = apim.getvariable('message.body');
```

Note: If the content type of the data is neither XML nor JSON, the `apim.getvariable()` function returns a NodeList object consisting of one binary node, which must be converted to a string. If the content really is XML or JSON, you must then parse this string, as illustrated in the following example:

```
var data = apim.getvariable('request.body');

// if a nodelist was returned and the type is 13 (BLOB/Binary Node), convert it
// to a Buffer, which can then be converted to a string
if ((data.item && data.length > 0 && data.item(0).nodeType === 13)) {
  data = data.item(0).toBuffer().toString();
}

// if the string really is XML or JSON, then now add code to parse it with
// the appropriate XML or JSON parse function
      .
      .
      .
```

Read input asynchronously

The following code snippets show the `apim.readInput()` calls that you can use to perform a JavaScript callback function to read input data asynchronously into a variable. JSON input is returned as a JavaScript object. XML data is returned as a NodeList object (DOM). Other types of input are returned as a Buffer object.

```
apim.readInput(callback(err,input) {});
apim.readInputAsJSON(callback(err,json) {});
apim.readInputAsXML(callback(err,nodelist) {});
apim.readInputAsBuffer(callback(err,buffer) {});
```

Note: The `apim.readInput()` function attempts to determine the input data type and call the appropriate `apim.readInputAstype()` function in order to return the data in the correct format. However, to ensure that the correct data type is returned, use the `apim.readInputAstype()` function.
The `apim.readInputAstype()` function reads the data from either the INPUT context (for example `session.INPUT`), or from a policy output context (for example `policy.output`), depending on whether a previous policy had been called that had written output to a policy output context. This function then calls the underlying IBM DataPower GatewayScript `readAstype` method on the relevant context to read the data, and then use JavaScript callbacks to return the data to a variable. For more information about DataPower methods, see Gateway programming model and GatewayScript.

The following is an example of how to use the `apim.readInputAsJSON()` callback function to get data into a variable that is called *json*:

```
apim.readInputAsJSON(function (error, json) {
if (error)
{
// handle error
}
else
{
// the json parameter will contain the json data that has been read
// process the json object in some way and write to the output context
if (json.test=='true')
{
// if json data contains a variable called test that is set to true, then also add some test data
json.data = 'This is my test data'
}
session.output.write(json);
// write to the output context
}
});
```

Configure error information

The following code block shows an example of how to configure the policy implementation to produce error information by using the `apim.error()` function. In this example, `MyError` is thrown to the assembly flow. If there is a catch handler it catches this error, otherwise the assembly skips the execution of the flow and sends a `500 Internal Error` response.

```
apim.error('MyError', 500, 'Internal Error', 'Some error message');
```

where:

- `MyError` is the name of the error.
- `500` is the HTTP code of the required error message.
- `Internal Error` is the HTTP reason phrase for the error.
- `Some error message` is the suggested action for the user.

Accessing the caught exception in a catch block

The following example shows how, in the `catch` block of an API assembly, you can obtain the details of the current caught exception. A possible use would be to create a custom error response using the details of the caught exception.

```
let exception = apim.getError();
```

The function returns a JSON object; for example:

```
{
  "name": "OperationError",
  "message": "This is a thrown Operation Error",
  "policyTitle": "Throw Operation Error",
  "status": {
    "code": "500",
    "reason": "Internal Server Error"
  }
}
```

Write output

The following example shows how to write data into the output, in this case the JSON data `'{ "status": "created" }'`, by using the `session.output.write` variable:

```
session.output.write('{ "status": "created" }');
```

The `session.output.write` variable is a standard GatewayScript method that writes data to the output context. For more information, see Contexts and sessions.
Use the following function to set the format of the content that is written to the `session.output` variable:

```
apim.output('application/type');
```

For example, if you were creating a policy that called:

```
session.output.write('<test>this is some xml data</test>');
```

the policy would write XML data to the output context. You would need to configure the policy to also call

```
apim.output('application/xml');
```

to tell the system that the output is XML. It can cause issues in the processing of the policy if the actual output context format, and the format that is specified in `apim.output`, are different.
Note: If you use `apim.setvariable` to manipulate `message.body`, you must immediately follow the `apim.setvariable` function call with an `apim.output` function call that specifies the content type of the payload that was written to `message.body` by `apim.setvariable`.

API Gateway only

Gemini invoke

Use the Gemini invoke policy to invoke Gemini operations.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see gemini-invoke.

About

The Gemini invoke policy provides access to six Gemini operations:

- **`POST models/[model]:generateContent`**
- **`POST models/[model]:countTokens`**
- **`POST models/[model]:embedContent`**
- **`POST models/[model]:batchEmbedContents`**
- **`GET models/[model]`**
- **`GET models`**

The Gemini invoke policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Gemini invoke policy properties

Property label	Required	Description	Data type
Title	No	Gemini invoke chat completions	string
Description	No	A description of the policy.	string
Gemini Operation	Yes	The Gemini operation to invoke; must be one of the following operations: • **`POST models/[model]:generateContent`** An HTTP POST operation for **`generateContent`**. See Generating Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:countTokens`** An HTTP POST operation for **`/countTokens`**. See Counting tokens in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:embedContent`** An HTTP POST operation for **`embedContent`**. See Embed Content in the Gemini API documentation for sample request and response examples. • **`POST models/[model]:batchEmbedContents`** An HTTP POST operation for **`batchEmbedContents`**. See Batch Embed Content in the Gemini API documentation for sample request and response examples. • **`GET models`** An HTTP GET operation for **`/models`**. See List Models in the Gemini API documentation for sample response examples. • **`GET models/[model]`** An HTTP GET operation for **`/models/[model]`**. See Retrieve model in the Gemini API documentation for sample response examples.	string
Gemini API Key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate Gemini requests.	string
Enable response caching	No	Response caching is enabled by default to optimize API performance; however, you can disable it if needed for your API. When response caching is enabled, then when a request is sent to the Gemini service, the response cache is inspected to determine if the request payload has an associated cached response. If so, that cached response and its associated HTTP response headers are placed into the DataPower API Gateway context message specified by the Output Message property. If there is no cached response, the request is passed to the Gemini service, and the response is cached for subsequent operations using the time-to-live specified in the Response Cache Expiration property.	boolean
Response Cache Expiration	No	The duration of the cache (the time-to-live). The minimum duration is 60 seconds and the maximum duration is 86400 seconds (1 day) -- any value outside of that range will fail validation when the API is published, even if the value is accepted in this field.	integer
Cache Scope	No	A string that adds uniqueness to the key used to store a cached response. Adding a cache scope enables the same request to be saved in multiple cache entries.	string
Gemini Operation Path Parameters	No	For operations that have a path parameter designated with a path parameter name in square brackets in the operation, specify the name of the parameter and the value separated by a colon. If the operation has more that one path parameter, each path parameter designation should be separated with a comma. For example, for operation **`GET models/[model]`**, the path parameter property would be specified as **`model:somename`**. Note: If a path parameter is required for the operation selected but was not provided, the invoke operation will fail. However, for operations that don't require a path parameter, any provided path parameter will be ignored.	string
Gemini Operation Query Parameters	No	For operations that support query parameters, specify a query parameter string that specifies the name of the parameter and value separated with an equal sign character. If more than one query parameter is supported, each query parameter would be separated with an ampersand character. The supported operations at this time do not support query parameters, although operations that could be supported in the future would support query parameters.	string
Output Message	No	The name of the DataPower API Gateway context message that receives the Gemini response. By default, this property uses message as the value, which enables the response to be accessible by subsequent API policies in **`message.body`** and **`message.headers`**.	string

Generate JWT

Use the Generate JWT security policy in IBM® API Connect to generate a JSON Web Token (JWT).

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.1.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see jwt-generate.

About

JSON Web Token (JWT) is a compact, URL-safe way of representing claims that are to be transferred between two parties. The Generate JWT policy enables you to generate claims and configure whether they are to be used as the payload of a JSON Web Signature (JWS) structure, or as the plain text of a JSON Web Encryption (JWE) structure. Specifying the cryptographic material for both the JWS and the JWE produces a nested JWT that is both digitally signed and encrypted. The JWT is then assigned to the Authorization header as a Bearer token (the default option), or to the runtime variable in the JSON Web Token (JWT) property, if specified.

Note:

- For algorithm types HS256, HS384, and HS512 the cryptographic objects referenced must be a Shared Secret Key.
- For algorithm types RS256, RS384, RS512, ES256, ES384, ES512, PS256, PS384, PS512 the cryptographic objects referenced must be a Crypto Key (private key).
- The cryptographic material can be provided through a JSON Web Key (JWK).
- If both a cryptographic object and a JWK are specified, the cryptographic object is used to sign the JWT.

Prerequisites

The following prerequisites apply:

- If you are using one or more cryptographic objects (crypto objects), they must be located in the API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or certificate that is needed to encrypt or sign the JWT contents.
- If a JSON Web Key (JWK) is being used, it must be referenced by a runtime variable.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. Generate JWT policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`jwt-generate`**.	string
Description	No	A description of the policy.	string
JSON Web Token (JWT)	No	Runtime variable in which to place the JWT that is generated. The default value is: **`generated.jwt`**. However, if not set, the JWT that is generated is written to the Authorization Header as a Bearer token.	string
JWT ID Claim	No	Indicates whether a JWT ID (jti) claim should be added to the JWT. If selected, the property is set to **`true`**, and a UUID is generated and set as the JTI claim value.	boolean
Issuer Claim	Yes	Runtime variable from which the Issuer (iss) claim string can be retrieved. This claim represents the Principal that issued the JWT. The default value is: **`iss.claim`**	string
Subject Claim	No	Runtime variable from which the Subject (sub) claim string can be retrieved.	string
Audience Claim	No	Runtime variable from which the Audience (aud) claim string can be retrieved. Multiple variables are set by using a comma-separated string.	string
Validity Period	Yes	The length of time (in seconds), that is added to the current date and time, in which the JWT is considered valid. The default value is **`3600`**.	integer
Private Claims	No	Runtime variable from which a valid set of JSON claims can be retrieved. These claims are added to any set of claims specified previously.	string
Sign JWK variable name	No	Runtime variable that contains the JWK that is used to sign the JWT.[1]	string

Property label	Required	Description	Data type
Cryptographic Algorithm	No	The cryptographic algorithm to use. Valid values are: • HS256 • HS384 • HS512 • RS256 • RS384 • RS512 • ES256 • ES384 • ES512 • PS256 • PS384 • PS512	string
Sign Crypto Object	No	The cryptographic object to use to sign the JWT.[1]	string
Sign KID value	No	The customized `kid` value for JWT signing.	string
Encryption Algorithm	No	The encryption algorithm to use. Valid values are: • A128CBC-HS256 • A192CBC-HS384 • A256CBC-HS512	string
Encrypt JWK variable name	No	Runtime variable that contains the JWK to use to encrypt the JWT.	string
Key Encryption Algorithm	No	The key encryption algorithm to use. Valid values are: • RSA1_5 • RSA-OAEP • RSA-OAEP-256 • dir • A128KW • A192KW • A256KW	string
Encrypt Crypto Object	No	The cryptographic object to use to encrypt the claim.	string
Encrypt KID value	No	The customized `kid` value for JWT encryption.	string

Example

```
    - jwt-generate:
        version: 2.1.0
        title: jwt-generate
        description: New jwt-generate v2.1.0 policy.
        jwt: generated.jwt
        jti-claim: true
        iss-claim: iss.claim
        sub-claim: sub.claim
        aud-claim: aud.claim
        exp-claim: 3600
        private-claims: private.claims
        jws-jwk: jws.jwk
        jws-alg: HS256
        jws-crypto: jwsCryptoObjectName
        custom-kid-value-jws: jws.kid
        jwe-enc: A128CBC-HS256
        jwe-jwk: jwe.jwk
        jwe-alg: RSA1_5
        jwe-crypto: jweCryptoObjectName
        custom-kid-value-jwe: jwe.kid
```

Errors

The following error can be thrown while the policy is being executed:

- `RuntimeError` - a generic error that captures all errors that occur during the execution of the policy. Upon failure, the detailed error message that is received from the underlying JOSE module is written to the default system log as an error message. This detailed error message is also assigned to the runtime variable jwt-generate.error-message, so it can be retrieved via catch.

If a catch is not configured, in the case of a failure the Generate JWT policy returns an HTTP code 500 `Invalid-JWT-Generate` failure. The detailed error message from the underlying JOSE module can be found in the system log.
Attention: If you are an API developer who is troubleshooting a failure that one of your customers had with your API, consider the security risks before sending a customer the exact content of the log message. You can avoid the possibility of someone launching an attack based on the information that they receive from the log message by sending the customer only general information about the message.

Related information

- Introduction to JSON Web Tokens

[1] A JWK and a Crypto Object are both valid ways of providing the cryptographic data necessary to sign the JWT. However, if both data types are specified, only the Crypto Object is used. If you are using one or more cryptographic objects (crypto objects), they must be located in the API Connect domain on the DataPower appliance. The cryptographic objects must reference the Shared Secret Key or certificate that is needed to encrypt or sign the JWT contents.

GraphQL Cost Analysis

Use the GraphQL Cost Analysis policy to return a cost analysis of a target query.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see graphql-cost-analysis.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL Cost Analysis policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`graphql-introspect`**.	string
Description	No	A description of the policy.	string
Input	No	A variable in the API context that contains the input to the GraphQL cost analysis. The content of the body field of the variable is the GraphQL cost query. By default, the variable name is **`message`**. The query should be in the format as specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **`__cost`**.	string
Output	No	A variable in the API context where the results of the GraphQL cost analysis are stored. The content of the body field of the variable is the result of GraphQL cost analysis. The default variable name is the same as that of the variable specified for the input field. Therefore, by default, the input of the GraphQL cost analysis is overwritten by the output.	string
Target	No	A variable in the API context that contains the target for the GraphQL cost analysis. The content of the body field of the variable is the GraphQL context. By default, the variable name is **`graphql_execute_args`**. The target context specifies the query to analyze and, optionally, the result of the query execution.	string

GraphQL Execute

Use the GraphQL Execute policy to execute a GraphQL query by using sub-queries.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0 (DataPower API Gateway Version 10.0.4.0 and later) 2.1.0 (DataPower API Gateway Version 10.5.2.0 and later)

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see graphql-execute.

About

The GraphQL Execute policy executes a GraphQL query by using sub-queries. The policy splits up the original GraphQL query into different sub-queries that can then be processed in different ways. The GraphQL Execute policy supports the following four different sub-queries as targets:

1. **`root`**; contains the core GraphQL query that you want to invoke on the backend.
2. **`__introspection`**; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend.
3. **`__rateLimit`**; contains the **`__rateLimit`** query that specifies the different rate limit data that you want to receive.
4. **`__cost`**; contains the **`__cost`** query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **`__cost`**.

The **`root`**, **`__rateLimit`**, and **`__introspection`** targets can be executed in any order, or at the same time. The **`__cost`** target can be executed at any time if no response data is expected. If response data is expected, then the **`__cost`** target is executed after the **`root`** target in order to accurately return correct response cost data. After all the targets are executed, the GraphQL Execute policy combines all of the responses together. To enable the responses of the individual targets to be correctly merged with each other into a final, single response, the GraphQL Execute policy must include all of the introspection types that are associated with each level of the response data.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL Execute policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`graphql-execute`**.	string
Description	No	A description of the policy.	string
Target	No	The target for the sub-queries. Valid values are: • **`root`**; contains the core GraphQL query that you want to invoke on the backend. • **`__introspection`**; contains the introspection query that can be processed locally on the DataPower API Gateway without having to invoke the backend. • **`__rateLimit`**; contains the **`__rateLimit`** query that specifies the different rate limit data that you want to receive. • **`__cost`**; contains the **`__cost`** query that specifies the different cost data that you want to receive. This query must be in the format that is specified in the IBM GraphQL Cost Directives specification, see Introspection of Cost Analysis Results: **`__cost`**.	string

GraphQL Introspect

Use the GraphQL Introspect policy to introspect a GraphQL schema.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	2.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see graphql-introspect.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. GraphQL Introspect policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy. The default value is **`graphql-introspect`**.	string
Description	No	A description of the policy.	string
Input	No	A variable in the API context that contains the input to introspect. The content of the **`body`** field of the variable is the input to introspect. By default, the variable name is **`message`**.	string
Output	No	A variable in the API context where the results of the introspection are stored. The content of the **`body`** field of the variable is the result of GraphQL introspection. The default variable name is the same as that of the variable specified in the Input field. Therefore, by default, the input of the introspection is overwritten by the output.	string

API Gateway only

IBM Cloud Authentication

Use the IBM Cloud Authentication policy to authenticate with IBM Cloud and obtain an API key that can be used when sending requests to watsonx.ai.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® API Gateway	1.0.0

This topic describes how to configure the policy in the assembly user interface; for details on how to configure the policy in your OpenAPI source, see ibm-cloud-authentication.

About

The IBM Cloud Authentication policy provides an API key to the IBM Access Manager and, if successfully authenticated, returns a Bearer token to be used by all subsequent watsonx.ai operation requests. The Bearer token is cached and will be valid for approximately 60 minutes. A new token is retrieved when a response for the API key was not cached. or expired.

The IBM Cloud Authentication policy supports the properties shown in Table 2.

Properties

The following table lists the policy properties, indicates whether a property is required, specifies the valid and default values for input, and specifies the data type of the values.

Table 2. IBM Cloud Authentication policy properties

Property label	Required	Description	Data type
Title	No	The title of the policy; the default value is `ibm-cloud-authentication`. The title displays in the API assembly editor in the UI.	string
Description	No	A description of the policy.	string
API key	Yes	The API key, or a variable reference to the variable that contains an API key. The API key is used to authenticate subsequent watsonx.ai requests.	string

Invoke

Apply the Invoke policy to call another service from within your assembly. The response from the backend is stored either in the variable `message.body` or in the response object variable if it is defined. The policy can be used with JSON or XML data, and can be applied multiple times within your assembly.

Note: The Invoke policy does not support responses with multipart form data, that is, when the response is set to `Content-Type: multipart/related`.

Gateway support

Table 1. Table showing which gateways support this policy, and the corresponding policy version

Gateway	Policy version
DataPower® Gateway (v5 compatible)	1.0.0
DataPower API Gateway	2.0.0 2.1.0 (DataPower API Gateway Version 10.0.1.1 or later) 2.2.0 (DataPower API Gateway Version 10.0.2.0 or later) 2.3.0 (DataPower API Gateway Version 10.0.3.0 or later)

- **Configuring the Invoke policy for DataPower API Gateway**
  Follow these steps to configure the Invoke policy for DataPower API Gateway in the assembly user interface.
- **Configuring the Invoke policy for DataPower Gateway (v5 compatible)**

API Gateway only

Configuring the Invoke policy for DataPower API Gateway

Follow these steps to configure the Invoke policy for DataPower® API Gateway in the assembly user interface.

About this task

Note: This topic describes the Invoke policy implementation in the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), see Configuring the Invoke policy for DataPower Gateway (v5 compatible). For information about the different types of gateway, see API Connect gateway types.
For details on how to configure the policy in your OpenAPI source, see invoke.

Procedure

1. In the navigation pane, click  Develop, then select the APIs tab.
   The Develop page opens.

2. Click the title of the API definition that you want to work with.
3. Select the Gateway tab, then click Policies in the navigation pane.
   For more information about working with the assembly editor for an API, see The assembly editor.
4. Find the Invoke policy in the palette, and drag the policy onto your canvas.
5. Specify the following properties.

Table 1. Invoke policy properties

Property label	Required	Description	Data type
Title	Yes	The title of the policy. The default value is **`invoke`**.	string
Description	No	A description of the policy.	string
URL	Yes	Specifies a URL for the target service. For a SOAP API, a URL is added by default. Where possible, the Invoke URL value is pre-supplied from information that is defined in the imported WSDL.	string
Backend type	No	Select one of the following options to determine how the payload is sent to the backend. Detect Detect the message type and send the payload to the backend accordingly. XML Package the payload as XML and send. If the message type is not XML, the operation fails. JSON Package the payload as JSON and send. If the message type is not JSON, the operation fails. Binary Package the payload as binary and send, regardless of the message type. GraphQL Package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. The default value is Detect.	string
GraphQL send type(policy version 2.2.0 and later)	Yes, if Backend type is set to GraphQL or Detect, and HTTP Method is set to POST or Keep	Select one of the following values to determine how the GraphQL payload is sent to the back end. Detect Detect the message type and send the payload to the back end accordingly. GraphQL Package the payload as GraphQL and send. If the message type is not GraphQL, the operation fails. JSON Package the payload as JSON and send. If the message type is not GraphQL, the operation fails. Note: GraphQL send type is supported only if Backend type is set to GraphQL or Detect, and HTTP Method is set to POST or Keep.	string
TLS profile	No	Specifies a TLS profile to use for the secure transmission of data.	string
Timeout	Yes	The time to wait before a reply from the endpoint (in seconds). The default value is **`60`**.	integer
Follow redirects	No	Specifies the behavior if the back-end server returns the HTTP status code **`301 Moved Permanently`**. If you select this checkbox, the **`invoke`** policy follows the URL redirection by making a further call to the URL specified in the **`Location`** header in the response. If you clear this checkbox, the **`invoke`** saves the **`301`** status code and the API call is considered to be complete. Note: The **`follow-redirect`** property is supported only by the DataPower API Gateway. If you are using the DataPower Gateway (v5 compatible), the **`invoke`** always follows the URL redirection; the **`proxy`** policy (not supported by the DataPower API Gateway) saves the **`301`** status code and completes the API call without following the URL redirection.	boolean
Username	No	The username to use for HTTP Basic authentication.	string
Password	No	The password to use for HTTP Basic authentication.	string
HTTP Method	Yes	The HTTP method to use for the Invoke. The following values are valid. • Keep • GET • POST • PUT • DELETE • PATCH • HEAD • OPTIONS The default value is **`GET`**. However, if set to **`Keep`**, or the property is removed from the source, the HTTP method from the incoming request is used.	string
HTTP Version (policy version 2.1.0 and later)	Yes	The HTTP version that will be used when connecting to the backend server. Select one of the following values. • HTTP/1.0 • HTTP/1.1 • HTTP/2 The default value is HTTP/1.1.	string
HTTP/2 Required (policy version 2.1.0 and later)	No	Select this checkbox to require that the server selects HTTP/2 during a TLS connection, otherwise the DataPower API Gateway rejects the connection and fails the request. For a non-TLS connection, a warning is logged stating that the requirement can't be enforced. This setting applies only if HTTP Version is set to HTTP/2.	boolean
Compression	No	Select this checkbox to enable Content-Encoding compression on upload. The checkbox is cleared by default.	boolean

Property label	Required	Description	Data type
